If the weight to be sustained be given, and the sectional dimensions of the bar be required, divide the weight given by one-third or one-quarter of the cohesive strength, and the square root of the quotient will be the side of the square. If the section be rectangular, the quotient must be divided by the breadth.

Tables I. and II. are derived chiefly from the summary in Rankine's *Civil Engineering*, p. 511, obtained from the experiments of Clay, Fairbairn, Hodgkinson, Mallet, Morin, Napier, Napier and Sons, Rennie, Telford, and Wilmot. Most of the remainder are from Rennie and other authorities.

1630s. English boiler-plates are stated to be of two classes: Yorkshire, and the manufacture of other districts, classed as Staffordshire.

1630*t*. The *tensile* strength of cast iron was long very much overrated when Tredgold estimated it at 20 tons. Captain Brown, however, put it at 7·26 tons; G. Rennie (*Phil. Trans.* 1818) obtained 8·52 and 8·66 tons; Barlow conjectured at least 10 tons from theoretical principles; Hodgkinson made the following experiments more recently;

Name and Quality of Iron.	Hot Blast Iron.		Cold Blast Iron.	
	Weight, lbs.	Mean. Tons cwt.	Weight, lbs.	Mean. Tons cwt.
Carron, No. 2 - -	13,892 12,993 13,629	13,505 = 6 0½	16,772 16,594	16,683 = 7 9

	Mean	7 4⅗	Mean	7 14

Low Moor, (Yorkshire,) No. 3, bore 6½ tons.
A mixture of irons, a mean of four experiments, gave 7 tons 7¾ cwt.

1630*u*. The mean of several experiments on the ultimate cohesive strength of a *wrought iron bar*, 1 inch square section, was:—

No. 11	experiments by Captain Brown, gave - -	56,000 lbs.	= 25·00	tons.
No. 9	,, by Telford, ,, - - -	65,520 ,,	= 29·25	,,
No. 10	,, by Brunel, ,, - - -	68,992 ,,	= 30·80	,,
No. 4	,, by Barlow, ,, - - -	56,560 ,,	= 25·25	,,
	Mean	61·768 lbs.	= 27·575	tons.

No. 3 experiments by Brunel, on hammered iron, gave 30·4, 32·3, and 30·8 tons respectively.

Several experiments by Cubitt, gave - - - 58,952 lbs. = 26 tons 6·3 cwt.

	Highest lbs.	Lowest lbs.	Mean lbs.	Breaking Weight. Tons.
188 bars, rolled, experimented upon by Kirkaldy,	68,848	44,584	57,555	= 25¾
72 angle irons ,, ,, ,,	63,715	37,909	54,729	= 24½
167 plates, lengthways ,, ,, ,,	62,544	37,474	50,737	= 21¾
160 plates, crossways ,, ,, ,,	60,756	32,450	46,171	

He states that 25 tons for bars and 20 tons for plates, are the amounts generally assumed.

1630*v*. The detailed experiments by Messrs. Clarke and Fairbairn, on the strength of *iron plates*, are given in the work by the latter, and in the *Engineers' Pocket Book* for 1861 and 1865. Clarke assumes the ultimate tensile strength of wrought iron plates at 20 tons per square inch, and of bars at 24 tons, and that within this former limit, its extension may be taken at $\frac{8}{100,000}$ of the length, per ton, per inch square of section.

The ultimate strength of plates drawn in direction of the fibre	experiment 1,	19·66 tons.
	„ 2,	20·2 „
„ „ „ „ broken across the fibre	„ 1,	16·93 „
	„ 2,	16·7 „

The ultimate *extension* was twice as great when the plate was broken in the direction of the fibre. The best scrap rivet iron, made by Messrs. Mare at their London works, broke on an average with 24 tons per square inch; the mean ultimate extension, which was uniform, was $\frac{1}{8}$ of the length.

Compression, &c.

1630*w*. *Compression* is the second of the forces under which Transverse strain is comprised. The following facts appear to be well established as to materials under a crushing force. I. The strength is as the transverse area or section. II. The plane of rupture in a crushed body is inclined at a constant angle to the base of the body. III. The measure of compression-strength is constant only within certain proportions of the height and diameter in any specimen. Hodgkinson found that twelve cylinders of teak wood furnished the following results:—

	½ inch diam.	inch diam.	2 inch diam.
Crushing weight	2439 lbs.	10,171 lbs.	40,304 lbs.
Proportion of weights	1 „	4·17 „	16·5 „

The areas being as the squares of the diameters an exact proportion would have been 1, 4, and 16; but some materials may possibly be found to have an increased apparent strength.

Table I., of Experiments on Timber Pillars, made by the Committee of the Institute of British Architects, 1863–64.

1630*x*. It is now a well ascertained circumstance that the crushing strength of a body varies according to its relative height and breadth. Hodgkinson remarks, "When bodies are crushed they give way by a wedge sliding off in an angle dependent on the nature of the material; and in *cast iron* the height of this wedge is about $1\frac{1}{2}$ of the diameter or thickness of the base of the wedge." Gregory puts the angle of this wedge at 34°. If the body to be crushed is shorter than would be sufficient to admit a wedge of the full length to slide off, then it would require more than its natural degree of force to crush it; because the wedge itself must either be crushed, or slide off in a direction of greater difficulty. If, on the other hand, the height of the body to be crushed be much greater than the length of the wedge, then the body will sustain some degree of flexure, and fracture will be facilitated in consequence. *Phil. Trans.*, 1840, cxxx. page 419. Warr says, "It is highly probable that none of Hodgkinson's values would agree with the most careful trial on any similar woods." See 1502*d*, *et seq.*

1630*y*. The power of resistance to compression of cast-iron was heretofore very much overrated. It has now been well ascertained by experiment that a force of 93,000 lbs. upon an inch square will crush it; and that it will bear 15,300 lbs. upon an inch square without permanent alteration.

TABLE OF THE COMPRESSION OF A CAST IRON BAR (AS A PILLAR), 10 feet long and 1 inch square.

1630*z*. Hodgkinson's experiments in 1851 on the ultimate strength of cast iron, the pieces being placed in an iron box or frame, gave a mean in 81 trials of 107,750 lbs. per square inch, or 48 tons 2 cwt.; and the crushing force to the tensile, as 6·507 to 1. Rennie's calculations gave only 40 tons per square inch for the lowest estimate.

TABLE OF THE CRUSHING OF CUBES OF IRON.

Materials.	Crushing Weight.		Materials.	Crushing weight.	
		Square inch.			Square inch.
A cube of $\frac{1}{8}$ inch side	lbs.	lbs.		lbs.	lbs.

Cast lead	483				
		(Rennie)			(Rennie)

1631. Hodgkinson, "considering the pillar as having two functions, one to support and the other to resist flexure, it follows that when the material is incompressible (supposing such to exist), or when the pressure necessary to break the pillar is very small on account of the greatness of its length compared with its lateral dimensions, then the strength of the whole transverse section of the pillar will be employed in resisting flexure; when the breaking pressure is one-half of what would be required to crush the material, one-half only of the strength may be considered as available for resistance to flexure, whilst the other half is employed to resist crushing; and when, through the shortness of the pillar, the breaking pressure is so great as to be nearly equal to the crushing force, we may consider that no part of the strength of the pillar is applied to resist flexure." Thus he assumed that the real breaking weight would be equal to the breaking weight as obtained for the long columns, multiplied by the force requisite to crush it without flexure; and divided by the same two quantities added together, minus the pressure which it would support as flexible, without being weakened by crushing. The formula thus found for calculating the strength was $\frac{Wc}{W+\frac{3c}{4}}$.

Here W breaking weight of long pillars, and c crushing force of the iron. (Warr and Gregory.)

1631*a*. Euler, treating on the strength of pillars purely on theoretical grounds, showed that the strength varied as the fourth power of the diameter, and inversely as the square of the length of the pillar. The strength of similar pillars increases as the square of their diameter; and as the area is as the square of the diameter, the strength increases as the area of the pillar (Warr.)

1631*b*. The strength of a pillar or a column, or the power of resistance to compressive force, is obtained by the law that the resistance to crushing is as the cube of the thickness multiplied by the width, and this divided by the square of the length. Therefore in columns of equal length and thickness, the resistance is as their width; and in equal lengths and widths, it is as the cube of the thickness. If the width and thickness be equal, or if the pillar be square, the resistance is inversely as the square of its length.

I*a*.	The formula for a rectangular *pillar* of oak, is	$\frac{R\,b\,d^3}{4d^2+\cdot5l^2}=W$ lbs.	R =	3,960.
I*b*.	„	„ cast iron, is $\frac{R\,b\,d^3}{4d^2+\cdot18l^2}=W$ lbs.	R =	15,300.
I*c*.	„	„ wrought iron, is $\frac{R\,b\,d^3}{4d^2+\cdot16l^2}=W$ lbs.	R =	17,800.
II*a*.	„	solid *cylinder* of oak, is $\frac{R\,d^4}{4d^2+\cdot5l^2}=W$ lbs.	R =	2,470.
II*b*.	„	„ cast iron, is $\frac{R\,d^4}{4d^2+\cdot18l^2}=W$ lbs.	R =	9,562.
II*c*.	„	„ wrought iron, is $\frac{R\,d^4}{4d^2+\cdot16l^2}=W$ lbs.	R =	11,125.

Here l length in feet; b breadth in inches; d diameter in inches; R resistance to compressive force; W breaking weight of the pillar or cylinder. (Tredgold, *Cast Iron.*)

1631*c*. The relative strengths of long columns of different materials, but of the same dimensions, are as follows:—

Cast iron.	Cast steel.	Wrought iron.	Dantzic oak.	Red deal.	
1,000	2,518	1,745	108·8	78·5	(Gregory)

			English oak.	Red Pine.	Teak.	Larch.	Elm.	
100	180	79	18	15	19	12	10	(Hurst.)

1631*d*. Hodgkinson, *Cast Iron*, 1846, states that there are general properties common to wrought iron, steel and wood. It appeared from experiments that long (solid) pillars break first at, or near to, the middle; this occurred in all cases. Pillars were, therefore, tried, having a middle diameter of from $1\frac{1}{4}$ to 2 inches, the ends being 1 inch. The strength was not increased according to the increase of the middle diameter, but appeared to be from $\frac{1}{6\cdot62}$ to $\frac{1}{8\cdot05}$, or from one-seventh to one-eighth; they did not, however, fracture in the middle, as did those of uniform diameter. He found that—

The strength, as dependent on the diameter, was on the mean - 3·736
„ „ „ length, „ „ - 1·7

I. The formula given by him for *long* solid cylindrical pillars (when l exceeds 30 d) with flat ends and fixed, is $\frac{44\cdot16\text{ tons }d^{3\cdot33}}{l^{1\cdot7}}=W$ tons, or (33,379 lbs. = 14·901 tons). The formula for ditto with rounded ends (or when l is less than 30d and exceeding 15d, is $\frac{14\cdot9\text{ tons }d^{3\cdot76}}{l^{1\cdot7}}=W$ tons, or (98,922 lbs. = 44·16 tons). Here d external diameter inches; l length feet; $\frac{1}{10}$ of W to be taken for safe weight.

II. For *short pillars*, below 30 times their diameter in height with flat ends, or 15 times their diameter in pillars with rounded ends, the above formulæ do not apply.

III. For *solid columns*, when the length is less than 30*d*, the formula is $\frac{49\,W\,a}{W+37\,a} = W^1$. Here W^1 crushing weight of short column in tons; a sectional area of solid part of columns inches. In *hollow columns* the thickness of metal should not be less than $\frac{d}{12} \cdot \frac{W\,C}{W+\frac{3}{4}C} = W^1$ tons. Here W as found above for long columns; C crushing force of material × sectional area of column; and W^1 crushing weight of short columns.

1631*e*. The formula for a rectangular pillar of timber, fixed at both ends $\frac{7,200\,a}{1+\frac{l^2}{250\,h^2}} = W$ lbs.

" cylindrical pillar of cast iron " $\frac{80,000\,a}{1+\frac{l^2}{400\,h^2}} = W$ lbs.

" rectangular strut of wrought iron " $\frac{36,000\,a}{1+\frac{l^2}{3,000\,h^2}} = W$ lbs.

A pillar rounded or jointed at both ends $\frac{80,000\,a}{1+4\times\frac{l^2}{400\,h^2}} = W$ lbs.; or 36,000, or 7,200, as the case may be. (Rankine, from Gordon, and Hodgkinson.)

1631*f*. The formula for a circular post or pillar $\frac{C\,d^4 \text{ inches}}{l^2 \text{ feet}} = W$ tons, or safe load $= \frac{1}{10}\,W$.

" square pillars $\frac{1{\cdot}7\,C\,s^4}{l^2} = W$ " "

" rectangular column $\frac{1{\cdot}7\,C\,b\,t^3}{l^2} = W$ " "

Here b breadth t least thickness in inches; s side in inches; d diameter; and C Teak 15; English oak 14; Canadian oak 13; Baltic oak 12; Red pine 12; Riga fir 11; Ash 12; Beech 11; Larch 9; and Elm 8. (Hurst.)

1631*g*. In order to give lateral stiffness to a flat-ended pillar, its ends should be spread so as to form a capital and base, whose abutting surfaces should be "faced" in the lathe, or planed, to make them exactly plane and perpendicular to the axis of the pillar. For the same reason, when a cast iron pillar consists of two or more lengths, the ends of those lengths should be made truly plane and perpendicular to the axis of the pillar by the same process, so that they may abut firmly and equally against each other; and they should be fastened together by at least four bolts passing through projecting flanges. (Rankine.)

1631*h*. *Hollow Columns.*—With an equal quantity of metal, a round column cast hollow is far stronger than one cast solid. The best form for cast iron columns is to make the inner diameter five-eighths of the size of the exterior diameter. The ring thus formed of the section of the column increases in strength according to the thinness, but the size of it must be kept within practical limits. If, in casting a hollow column, the core is driven to one side, the column of course cannot be loaded to its full resistance; it will not carry more than the thinnest part of it is strong enough to bear. Hollow columns, therefore, require particular care in casting them. Hodgkinson noticed in hollow pillars above 30 times as long as their diameter, that although the pillars were generally thicker on one side than the other, yet in bending, the compressed was always the thinner side; and as cast iron resists compression with above six times the force with which it sustains tension, *no danger resulted* from this almost unavoidable difference of thickness.

I. The formula given by him for a *hollow cylinder* not less than 15 times its diameter in height, with rounded ends, is $\frac{13{\cdot}0 \text{ tons } d^{3{\cdot}76} - d_1^{3{\cdot}76}}{l^{1{\cdot}7}} = W$ tons.

II. For the same when not less than 30 times its height, with flat ends and fixed by discs, is $\frac{44{\cdot}3 \text{ tons } d^{3{\cdot}35} - d_1^{3{\cdot}55}}{l^{1{\cdot}7}} = W$ tons.

III. When the length is equal to 20 diameters, the value of W is =77,817 lbs. or 34·7 tons.

Gregory has adopted an average of $d^{3{\cdot}6}$ in both of these formulæ.

IV. For *short pillars*, below those lengths, the formulæ do not apply, as the strength of the column becomes modified in consequence of its being then partially crushed as well as bent.

Stancheons and Struts.

1631*i*. Gordon's formula for the ultimate strength of *wrought iron struts* of a solid rectangular section fixed at the ends, as deduced from Hodgkinson's experiments, is $\frac{36,000}{1+3000\frac{l^2}{b^2}} = \frac{W \text{ or load}}{a \text{ or sect. area}}$. ($b$ least thickness). For other forms of cross section, approximate rules have been given. But it may be, in many cases, more satisfactory to take into account the least "radius of gyration" of the cross section; and for that purpose the formula may be put in the following shape: $\frac{36,000}{1+\frac{l^2}{36,000\,r^2}} = \frac{W}{a}$. Here r^2 is the mean of the

squares of the distances of the particles of the cross section from a neutral axis traversing its centre of gravity in that direction which makes r^2 least. For hinged ends, take $\frac{1}{4}$ or 9,000 is to be substituted for 36,000. The value of r^2 for a solid rectangle, least dimension $= b$, then $\frac{b^2}{12}$. For a thin square cell, side $= b$, then $\frac{b^2}{6}$. For a thin rectangular cell, breadth $= b$, depth $= h$, the $\frac{12}{h^2 \cdot \frac{h+b}{h+3b}}$. For a solid cylinder, diameter $= b$, then $\frac{b^2}{16}$. For a thin cylindrical cell, diameter $= b$, then $\frac{b^2}{8}$. For an angle iron of equal ribs, breadth of each $= b$, then $\frac{b^2}{24}$. For an angle iron of unequal ribs, greater $= b$, lesser $= h$, then $\frac{b^2h^2}{12(b^2+h^2)}$. For a cross of equal arms $\frac{b^2}{24}$. For H iron, breadth of flanges $= b$, their joint area $=$ B, area of web $=$ A, then $\frac{b^2 \cdot \frac{A}{B}}{12}$. (Rankine, who follows out the subject further.)

1631*k*. *Stancheons* of cast iron are recommended to be used in lieu of cast iron *columns*. The form shown in *fig.* 613*x*. is generally considered as the best for use; the flanges which divide the length into three equal parts, are found to add considerably to the strength of the casting in resisting the tendency of its load to produce deflection from the vertical position. Hodgkinson's experiments show that while *cast iron* is the better material for a pillar whose length does not exceed 26 times the diameter, *wrought iron* is the better material when the length exceeds that limit. For pillars with hinged ends, about 13 times is the limit, but these results are roughly approximate only. In order to stiffen *wrought iron* struts, they are made of various forms in cross section, such as angle iron, T iron, double T iron, channel iron, &c. The cross is a very convenient form as in cast iron; it is generally built by riveting bars of simple forms together. Thus it may be made up of T irons riveted back to back, or four angle irons riveted back to back; or by one flat bar, two narrower flat bars, and four angle irons, all riveted together, as *fig.* 613*y*., and as used for the strut diagonals of the Warren girders in the Crumlin viaduct. The stiffest form for a wrought iron strut is that of a cell or built tube, *fig.* 614*a*., which may be cylindrical, rectangular, or triangular, as *fig.* 614*b*. When a wrought iron strut is considered as hinged at the end, that is generally effected by its abutting at each end against a cylindrical pin, by which it is connected with some other piece of the frame-work, in the manner already described for tie-bars. To fix its ends in direction, as it seldom has large abutting faces, it is in general necessary to fasten it to the adjoining pieces of the structure by several bolts or rivets.

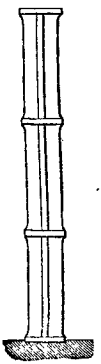

Fig. 613*x*.

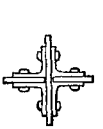

Fig. 613*y*.

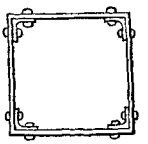

Fig. 614*a*.

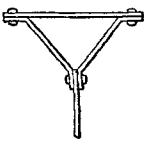

Fig. 614*b*.

1631*l*. Cast iron, from its great resistance to crushing, is peculiarly well suited for struts, especially those of moderate length. The best form containing a given quantity of metal is that of a hollow cylinder (*fig.* 614*c*.); the thickness of metal is seldom less than $\frac{1}{12}$ of the diameter. I. The formula for the *cylinder* has already been given; II. for a cast iron strut of a cross shape (*fig.* 614*d*.) the whole width being d, then $\frac{80{,}000}{1+\frac{3l^2}{400d^2}} = W$ lbs. per square inch of sectional area. III. For a hollow square (*fig.* 614*e*.), $d =$ diagonal, $\frac{80{,}000}{1+\frac{3l^2}{800d^2}} = W$, as before. IV. For a hollow cylinder (*fig.* 614*f*.), $d =$ diameter $\frac{80{,}000}{1+\frac{l^2}{400d^2}} = W$, as before. These formulæ refer to struts fixed at both ends. V. When they are hinged at the ends, the second term of each division is to be made four times as great.

1631*m*. With the ends fixed; I. the formulæ for a hollow tube (*fig.* 614*c*.) $a = 3000$, then $\frac{16s \text{ (or sectional area inches)}}{1+\frac{l^2 \text{ inches}}{a \; D^2 \text{ or (diam. inches)}}} = W$ tons.

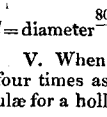

Fig. 614*c*.

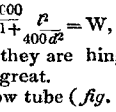

Fig. 614*d*.

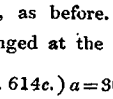

Fig. 614*e*.

Fig. 614*f*.

II. The formulæ for a cross with equal arms (*fig.* 614*d*) $a = 1000$.

III. The formulæ for an angle with equal sides (*fig.* 614*e*) $a = 1000$.

IV. When hinged at the ends, take $\frac{a}{4}$.

1631*n*. *Detrusion, or shearing*, denominates that kind of fracture, which would occur in the use of shears if their edges were blunt; or when the punch of a punching machine

makes a hole in a plate. Fairbairn has deduced the following laws from his experiments: I. That the ultimate resistance to shearing in any bolt or rivet, is proportional to the sectional area of the bar torn asunder. II. That the ultimate resistance of any bar to a shearing strain is nearly the same as the ultimate resistance of the same bar to a direct longitudinal tensile strain.

TABLE OF THE RESISTANCE OF MATERIALS TO SHEARING AND DISTORTION.

Materials.	Resistance to Shearing, per square inch.	Transverse Elasticity, or Resistance to Distortion, per square inch.
	lbs. avoirdupois.	lbs. avoirdupois.
Brass wire, drawn	- -	5,330,000
Copper	- -	6,200,000
Cast iron	27,700 to 32,500	2,850,000
Wrought iron	50,000	8,500,000 to 9,500,000
Pine, red	500 to 800	62,000 to 116,000
Fir, Spruce	600	—
Larch	970 to 1,700	—
Oak, English	2,300	82,000
Poplar	1,800	—
Ash and Elm	1,400	76,000
Deal	592	
Cast iron	73,000 ? Warr.	Rankine.
Wrought iron	45,000 to 53,000	

1631o. To find the length between the end of a beam and the foot of a strut or of a rafter, necessary to resist the thrust of the latter, so as to prevent the detrusion of the beam, the formula to be used is $\frac{4h}{bS}$ = the length in inches. Here b the breadth of the beam in inches; h horizontal thrust in pounds; and S, the cohesive strength in pounds of a square inch of the material. Tredgold states that 4 is a sufficient value for a factor of safety in this case; S = 600 lbs. per square inch for fir, and 2,300 lbs. for oak. The strap or bolt usually employed to bind the rafter and beam together, should be at as acute an angle as possible, and holds the rafter in its place should the end of the beam give way.

1631p. *Iron fastenings to joints.* In forming eyes by welding, at the end of iron bars for chain links and other purposes, the bar is found to be weaker than in its plain form. In iron plate work, the joints are made by riveting on which the whole efficacy of the built-up plate work depends. Taking the strength of the plain plate as 100, a double-

Fig. 614.

riveted plate will be 70; and a single-riveted, 56. Again, with *single plate jointings* having a top and bottom covering plate over the joint, and with half-inch rivets, as A, *fig.* 613*x*, the plates were torn asunder through the rivet-holes, with 24·41 tons in the square inch. With a *double plate*, having a single covering plate on the side of the joint, as B, the plates broke asunder by shearing off the rivets close to the plate, with 18·73 tons per square inch; but the rivets having been made larger, a similar strength to the previous experiment was realised. A plain plate broke with 22·78 tons mean value.

1631q. Fairbairn recommends the flanges or double plates to be used as long as possible, and the joints to be carefully united by covering plates, *chain-riveted*, as C, with three or more rows of rivets according to the widths of the plates. Eight rivets are required in each of the lines, four on each side of the joints, to give sufficient strength, and the area of the rivets collectively should be equal to the area of the jointed plates taken transversely through one line of the rivets, the area of the parts punched out in that line being deducted. These proportions give the required security to the joint, and afford nearly the same strength to a tensile strain as the solid plate; that is, if the covering plates be as much thicker as will give the same area of section through the rivet-holes as the unperforated double plate. (*par.* 1629*e*.)

1631r. Rivets are made of the most tough and ductile iron. It is essentially necessary that the rivet should tightly fit its hole; and the longitudinal compression to which rivets are subjected during the formation of its head, whether by hand or machinery, tends to produce that result. The diameter of a rivet for plates less than half an inch thick, is

about double the thickness of the plate. For plates of half an inch thick and upwards, about once and a half the thickness of the plate. The length of the rivet *before* clenching (which is effected whilst the rivet is red hot), measuring from the head, equals the sum of the thickness of the plates to be connected, added to $2\frac{1}{2}$ inches multiplied by the diameter of the rivet.

1631*s*. Steel rivets, fully larger in diameter than those used in riveting iron plates of the same thickness, being found to be greatly too small for riveting steel plates, the probability is suggested that the proper proportion for iron rivets is not, as generally assumed, a diameter equal to the thickness of the two plates to be joined. The shearing strain of steel rivets is found to be about a fourth less than the tensile strain. (Kirkaldy).

1631*t*. In the bridge over the Thames for the Charing Cross Railway, the holes were drilled and not punched. This is a point upon which engineers differ considerably; but most firms punch the holes. At Fairbairn's works at Manchester, drilling holes was considered to be more expensive without adding to the strength. Mr. Parkes thinks that the punching injured the iron considerably, and thought Fairbairn's experiments went to show it. (Society of Engineers, *Transactions*, 1865).

1631*u*. *Pins, keys, and wedges* are exposed, like rivets, to a shearing stress. The formula for finding their proper sectional area is the same. They must be held tightly in their seats; and in order that a wedge or key may not slip out of its seat, its angle of obliquity ought not to exceed the angle of repose of iron upon iron, which, to provide for the contingency of the surfaces being greasy, may be taken at about 4°. (Rankine).

1631*v*. If a *bolt or screw* has to withstand a shearing stress, its diameter is to be determined like that of a cylindrical pin. If it has to withstand tension, its diameter is to be determined by having regard to its tenacity. In either case the effective diameter of the bolt is its least diameter; that is, if it has a screw upon it, the diameter of the spindle inside the thread. The projection of the thread is usually one-half of the pitch; and the pitch should not in general be greater than one-fifth of the effective diameter, and may be considerably less. In order that the resistance of a screw or screw-bolt to rupture, by stripping the thread, may be at least equal to its resistance to direct tearing asunder, the length of the nut should be at least one half of the effective diameter of the screw; and it is often in practice considerably greater; for example, once and a half that diameter. The head of a bolt is usually about twice the diameter of the spindle and of a thickness which is usually greater than $\frac{2}{3}$ths of that diameter. (Rankine).

1631*w*. *Washers* are flat plates of iron, placed at the sides of timbers to secure them against the crushing action of the head and nut of a bolt whilst being screwed up. For fir, the diameter of the washer is made about $3\frac{1}{2}$ times that of the bolt; and for oak, about $2\frac{1}{2}$ times. When a bolt is placed oblique to the direction of the beam which it traverses, a notch should be cut in the timber perpendicular to the bolt, to receive the pressure of the washer equally, or notched to receive a bevelled washer of cast iron, one side of which fits the wood, and the other fits the axis of the bolt.

Torsion.

1631*x*. *Torsion*, or the resistance of bodies to being twisted, is found: I. When a body is fastened at one end and a force is applied at the other. II. When the force at one end is greater than at the other end. III. When the forces at the ends are in opposite directions, and are so applied as to twist the body. As this fact chiefly, if not entirely, concerns machinery in motion, we refer the student for more specific details to Warr, *Dynamics*, p. 269, who gives a table of "modulus of torsion" of various timbers and metals, derived from experiments made by Bevan, in *Phil. Trans.* 1829, p. 128. Approximate formulæ are given by Hurst:— I. When the shaft is circular, $\sqrt[3]{\frac{Wl}{C}} = d$. And $\frac{Cd^3}{l} = W$. II. When the shaft is square, $\sqrt[3]{\frac{4Wl}{5C}} = s$. Here d diameter inches; W weight pounds permanently sustained by the shaft; l length of lever in feet, at the end of which W acts; s side in inches; and C, cast steel 590; wrought iron 335; cast iron 330; gun metal 170; brass 150; copper 135; lead 34.

1631*y*. In the *Artizan* for 1857 and 1858 is an instructive *Enquiry into the Strength of Beams and Girders*, by S. Hughes, deserving attention. The chief authorities for the data contained in that article, and also in this section, are quoted herein.

CHAP. II.

MATERIALS USED IN BUILDING.

SECT. I.

STONE.

1636. It is not our intention to advert to the stone which the Continent affords for building purposes; a knowledge of the different kinds there found would be of no use to the English architect, and would occupy too much of our space as mere information. It is almost superfluous to say that the choice of stone for a building intended to be durable is of the very highest importance. "In modern Europe," it has been observed, "and particularly in Great Britain, there is scarcely a public building, of recent date, which will be in existence a thousand years hence. Many of the most splendid works of modern architecture are hastening to decay in what may be justly called the infancy of their existence, if compared with the dates of public buildings that remain in Italy, in Greece, in Egypt, and the East."

1637. The various sorts of stone take their names either from the places where they are quarried or from the substances which principally enter into their composition. The term "Freestone," which is used in a very arbitrary way, is, as its name implies, that sort which can be wrought with the mallet and chisel, or cut with the saw, an operation which cannot be performed upon granite, whose hardness requires it to be dressed with pointed tools of different weights and sizes. It includes the two great general divisions of Limestone and Sandstone. The limestone of Portland is that which has for many years past been chiefly used in the metropolis. Latterly, other sorts have found their way in from the provinces; and though, from many circumstances, we do not think it likely that Portland stone, from its facility of transport and other causes, will be altogether superseded, there is no doubt that its use is on the wane from the introduction of provincial sorts.

1638. We shall proceed, after some preliminary observations, to give, from the Report addressed in 1839 to the Commissioners of Woods and Forests on the occasion of selecting the stone for building the new Houses of Parliament, a view of the principal sorts of stone found and used in the island. A new edition was printed in 1845.

1639. The qualities requisite for a building stone are hardness, tenacity, and compactness. It is not the hardest stone which has always the greatest tenacity or toughness, for limestone, though much softer, is not so easily broken as glass.

1640. The *decay and destruction* of stone are accelerated by nearly the same causes as those which destroy rocks themselves on the surface of the globe. Such causes are of two kinds: those of decomposition and those of disintegration. The former affects a chemical change in the stone itself, the latter a mechanical division and separation of the parts. The effects of the chemical and mechanical causes of the decomposition of stone in buildings are much modified, according to their situation, as in the town or country. In populous and smoky towns the state of the atmosphere accelerates decomposition more than in those placed in the open country. (par. 1667.)

1641. "As regards the sandstones that are usually employed for building purposes, and which are generally composed of either quartz or siliceous grains, cemented by siliceous, argillaceous, calcareous or other matter, their decomposition is effected according to the nature of the cementing substance, the grains being comparatively indestructible. With respect to limestones composed of carbonate of lime, or the carbonates of lime and magnesia, either nearly pure or mixed with variable proportions of foreign matter, their decomposition depends, under similar circumstances, upon the mode in which their component parts are aggregated, those which are most crystalline being found to be the most durable, while those which partake least of that character suffer most from exposure to atmospheric influences.

1642. "The varieties of limestones termed Oolites (or Roestones) being composed of oviform bodies cemented by calcareous matter of a varied character, will of necessity suffer unequal decomposition, unless such oviform bodies and the cement be equally coherent and of the same chemical composition. The limestones which are usually termed '*shelly*,' from being chiefly formed of either broken or perfect fossil shells cemented by calcareous matter, suffer decomposition in an unequal manner, in consequence of the shells, which, being for the most part crystalline, offer the greatest amount of resistance to the decomposing effects of the atmosphere.

1643. "Sandstones, from the mode of their formations, are very frequently laminated,

more especially when micaceous, the plates of mica being generally deposited in planes parallel to their beds. Hence, if such stone be placed in buildings with the planes of lamination in a vertical position, it will decompose in flakes, according to the thickness of the laminæ; whereas, if it be placed so that the planes of lamination be horizontal, that is, most commonly upon its natural bed, the amount of decomposition will be comparatively immaterial.

1644. "Limestones, such at least as are usually employed for building purposes, are not liable to the kind of lamination observable in sandstones; nevertheless, varieties exist, especially those commonly termed *shelly*, which have a coarse laminated structure, generally parallel to the planes of their beds, and therefore the same precaution in placing such stone in buildings so that the planes of lamination be horizontal, is as necessary as with the sandstones above noticed.

1645. "The chemical action of the atmosphere produces a change in the entire matter of the limestones, and in the cementing substance of the sandstones according to the amount of surface exposed to it. The mechanical action due to atmospheric causes occasions either a removal or a disruption of the exposed particles, the former by means of powerful winds and driving rains, and the latter by the congelation of water forced into or absorbed by the external portions of the stone. These effects are reciprocal, chemical action rendering the stone liable to be more easily affected by mechanical action, which latter, by constantly presenting new surfaces, accelerates the disintegrating effects of the former.

1646. "Buildings in this climate are generally found to suffer the greatest amount of decomposition on their southern, south-western, and western fronts, arising doubtless from the prevalence of winds and rains from those quarters; hence it is desirable that stones of great durability should at least be employed in fronts with such aspects.

1647. "Buildings situated in the country appear to possess a great advantage over those in populous and smoky towns, owing to lichens, with which they almost invariably become covered in such situations, and which, when firmly established over their entire surface, seem to exercise a protective influence against the ordinary causes of the decomposition of the stone upon which they grow.

1648. "As an instance of the difference in degree of durability in the same material subjected to the effects of the atmosphere in town and country, we may notice the several frusta of columns and other blocks of stone that were quarried at the time of the erection of St. Paul's Cathedral in London, and which are now lying in the island of Portland, near the quarries from whence they were obtained. These blocks are invariably found to be covered with lichens, and although they have been exposed to all the vicissitudes of a marine atmosphere for more than 150 years, they still exhibit, beneath the lichens, their original forms, even to the marks of the chisel employed upon them, whilst the stone which was taken from the same quarries (selected, no doubt, with equal, if not greater, care than the blocks alluded to) and placed in the cathedral itself, is, in those parts which are exposed to the south and south-west winds, found in some instances to be fast mouldering away. Colour is of more importance in the selection of a stone for a building to be situated in a populous and smoky town, than for one to be placed in an open country, where all edifices usually become covered, as before stated, with lichens; for although in such towns those fronts which are not exposed to the prevailing winds and rains will soon become blackened*, the remainder of the building will constantly exhibit a tint depending upon the natural colour of the material employed.

1649. "Before we proceed to adduce a few examples of the present condition of the various buildings we have examined, we would wish to observe that those which are highly decorated, such as the churches of the Norman and pointed styles of architecture, afford a more severe test of the durability of any given stone, all other circumstances being equal, than the more simple and less decorated buildings, such as the castles of the fourteenth and fifteenth centuries, inasmuch as the material employed in the former class of buildings is worked into more disadvantageous forms than in the latter, as regards exposure to the effects of the weather; and we would further observe, that buildings in a state of ruin, from being deprived of their ordinary protection of roofing, glazing of windows, &c., constitute an equally severe test of the durability of the stone employed in them.

1650. "As examples of the degree of durability of various building stones in particular localities, the following may be enumerated. Of the sandstone buildings which we examined, we may notice the remains of Ecclestone Abbey, of the thirteenth century, near Barnard Castle, constructed of a stone closely resembling that of the Stenton quarry in the vicinity, as exhibiting the mouldings and other decorations, even to the dog's-tooth ornament, in excellent condition. The circular keep of Barnard, apparently also built of the same material, is in fine preservation. Tintern Abbey may also be noticed as a sandstone

* We must take leave to question this statement; as, for instance, in St. Paul's Cathedral we find the northern front peculiarly black, whilst the south front and south-western angle are comparatively white. This we have always considered to have arisen from the more constant action of the sun's rays upon them.

edifice that has to a considerable extent resisted decomposition; for although it is decayed in some parts, it is nearly perfect in others. Some portions of Whitby Abbey are likewise in a perfect state, whilst others are fast yielding to the effects of the atmosphere. The older portions of Ripon Cathedral, constructed of sandstone, are in a fair state of preservation. Rivaulx Abbey is another good example of an ancient sandstone building in a fair condition. The Norman keep of Richmond Castle in Yorkshire affords an instance of a moderately hard sandstone which has well resisted decomposition.

1651. "As examples of sandstone buildings of more recent date in a good state of preservation, we may mention Hardwicke Hall, Haddon Hall, and all the buildings of Craigleith Stone in Edinburgh and its vicinity. Of sandstone edifices in an advanced state of decomposition we may enumerate Durham Cathedral, the churches at Newcastle upon Tyne, Carlisle Cathedral, Kirkstall Abbey, and Fountains Abbey. The sandstone churches of Derby are also extremely decomposed; and the church of St. Peter at Shaftesbury is in such a state of decay that some portions of the building are only prevented from falling by means of iron ties.

1652. "As an example of an edifice constructed of a calciferous variety of sandstone, we may notice Tisbury Church, which is in unequal condition, the mouldings and other enrichments being in a perfect state, whilst the ashler, apparently selected with less care, is fast mouldering away.

1653. "The choir of Southwell Church, of the twelfth century, may be mentioned as affording an instance of the durability of a magnesio-calciferous sandstone, resembling that of Mansfield, after long exposure to the influences of the atmosphere.

1654. "Of buildings constructed of magnesian limestone we may mention the Norman portions of Southwell Church, built of stone similar to that of Bolsover Moor, and which are throughout in a perfect state, the mouldings and carved enrichments being as sharp as when first executed. The keep of Koningsburgh Castle, built of a magnesian limestone from the vicinity, is also in a perfect state, although the joints of the masonry are open in consequence of the decomposition and disappearance of the mortar formerly within them. The church at Hemmingborough, of the fifteenth century, constructed of a material resembling the stone from Huddlestone, does not exhibit any appearance of decay. Tickhill Church, of the fifteenth century, built of a similar material, is in a fair state of preservation. Huddlestone Hall, of the sixteenth century, constructed of the stone of the immediate vicinity, is also in good condition. Roche Abbey, of the thirteenth century, in which stone from the immediate neighbourhood has been employed, exhibits generally a fair state of preservation, although some portions have yielded to the effects of the atmosphere.

1655. "As examples of magnesian limestone buildings in a more advanced state of decay, we may notice the churches at York, and a large portion of the Minster, Howden Church, Doncaster Old Church, and others in that part of the country, many of which are so much decomposed that the mouldings, carvings, and other architectural decorations are often entirely effaced.

1656. "We may here remark, that, as far as our observations extend, in proportion as the stone employed in magnesian limestone buildings is crystalline, so does it appear to have resisted the decomposing effects of the atmosphere; a conclusion in accordance with the opinion of Professor Daniell, who has stated to us that from the results of experiments, he is of opinion 'the nearer the magnesian limestones approach to equivalent proportions of carbonate of lime and carbonate of magnesia, the more crystalline and better they are in every respect.'

1657. "Of buildings constructed of oolitic and other limestones, we may notice the church of Byland Abbey, of the twelfth century, especially the west front, built of stone from the immediate vicinity, as being in an almost perfect state of preservation. Sandysfoot Castle, near Weymouth, constructed of Portland oolite in the time of Henry VIII., is an example of that material in excellent condition; a few decomposed stones used in the interior (and which are exceptions to this fact) being from another oolite in the immediate vicinity of the castle. Bow and Arrow Castle, and the neighbouring ruins of a church of the fourteenth century, in the Island of Portland, also afford instances of the Portland oolite in perfect condition. The new church in the island, built in 1766, of the variety of the Portland stone termed *roach*, is in an excellent state throughout, even to the preservation of the marks of the chisel.

1658. "Many buildings constructed of a material similar to the oolite of Ancaster, such as Newark and Grantham Churches, and other edifices in various parts of Lincolnshire, have scarcely yielded to the effects of atmospheric influences. Windrush Church, built of an oolite from the neighbouring quarry, is in excellent condition, whilst the Abbey Church of Bath, constructed of the oolite in the vicinity of that city, has suffered much from decomposition; as is also the case with the cathedral, and the churches of St. Nicholas and St. Michael in Gloucester, erected of a stone from the oolitic rocks of the neighbourhood.

1659. "The churches of Stamford, Ketton, Colley Weston, Kettering, and other places

in that part of the country, attest the durability of the Shelley oolite, termed *Barnack Rag*, with the exception of those portions of some of them for which the stone has been ill-selected. The excellent condition of those parts which remain of Glastonbury Abbey show the value of a shelly limestone similar to that of Doulting, whilst the stone employed in Wells Cathedral, apparently of the same kind, and not selected with equal care, is in parts decomposed. The mansion, the church, and the remains of the abbey at Montacute, as also many other buildings in that vicinity, constructed of the limestone of Ham Hill, are in excellent condition. In Salisbury Cathedral, built of stone from Chilmark, we have evidence of the general durability of a siliciferous limestone; for, although the west front has somewhat yielded to the effects of the atmosphere, the excellent condition of the building generally is most striking.

1660. "In the public buildings of Oxford, we have a marked instance both of decomposition and durability in the materials employed; for whilst a shelly oolite, similar to that of Taynton, which is employed in the more ancient parts of the cathedral, in Merton College Chapel, &c., and commonly for the plinths, string-courses, and exposed portions of the other edifices in that city, is generally in a good state of preservation, a calcareous stone from Heddington, employed in nearly the whole of the colleges, churches, and other public buildings, is in such a deplorable state of decay, as in some instances to have caused all traces of architectural decoration to disappear, and the ashler itself to be in many places deeply disintegrated.

1661. "In Spofforth Castle we have a striking example of the unequal decomposition of two materials, a magnesian limestone and a sandstone; the former employed in the decorated parts, and the latter for the ashler or plain facing of the walls. Although the magnesian limestone has been equally exposed with the sandstone to the decomposing effects of the atmosphere, it has remained as perfect in form as when first employed, while the sandstone has suffered considerably from the effects of decomposition.

1662. "In Chepstow Castle, a magnesian limestone in fine preservation, and a red sandstone in an advanced state of decomposition, may be observed, both having been exposed to the same conditions as parts of the same archways; and in Bristol Cathedral there is a curious instance of the effects arising from the intermixture of very different materials, a yellow limestone and a red sandstone, which have been indiscriminately employed both for the plain and decorated parts of the building; not only is the appearance in this case unsightly, but the architectural effect of the edifice is also much impaired by the unequal decomposition of the two materials, the limestone having suffered much less from decay than the sandstone.

1663. "Judging, therefore, from the evidence afforded by buildings of various dates, there would appear to be many varieties of sandstone and limestone employed for building purposes which successfully resist the destructive effects of atmospheric influences; amongst these the sandstones of Stenton, Whitby, Tintern, Rivaulx, and Cragleith, the magnesio-calciferous sandstones of Mansfield, the calciferous sandstone of Tisbury, the crystalline magnesian limestones, or *Dolomites* of Bolsover, Huddlestone and Roche Abbey, the oolites of Byland, Portland, and Ancaster, the Shelly oolites and limestones of Barnack and Ham Hill, and the siliciferous limestone of Chilmark appear to be amongst the most durable. To these, which may all be considered as desirable building materials, we are inclined to add the sandstones of Darley Dale, Humbie, Longannet, and Crowbank, the magnesian limestones of Robin Hood's Well, and the oolite of Ketton, although some of them may not have the evidence of ancient buildings in their favour." The Report upon which we have drawn so largely, and from which we shall extract still larger drafts, then proceeds to close by a preference to limestones on account "of their more general uniformity of tint, their comparatively homogeneous structure, and the facility and economy of their conversion to building purposes," of which it prefers the crystalline; on which account, and its combination with a close approach to the equivalent proportions of carbonate of lime and carbonate of magnesia, for uniformity in structure, facility and economy in conversion, and for advantage of colour, the parties to the Report prefer the magnesian limestone or dolomite of Bolsover Moor and its neighbourhood. The Report deserves every commendation; upon the whole it has been well done, and is the first scientific step the government of this country has ever taken in respect of practical architecture. It, moreover, only cost the moderate sum of £1,400, including the many collections of specimens deposited in various institutions for reference.

1664. The following table presents a synoptical, and, to the architect, important view of the relative value, in every respect, of the principal species of stone which the various provinces of England afford for building purposes. It is taken from the Report so much quoted, the list of stones being considerably abridged. We should direct attention to the fact that facilities of conveyance have greatly modified the cost of each stone in London. It will be well also to notice the valuable "Quarry Returns" of building and other stones, the produce of the United Kingdom of Great Britain and Ireland, published in the *Memoirs of the Geological Survey of Great Britain*, &c., and edited by Robert Hunt, being Part II. for 1858, but published in 1860.

SANDSTONES.

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.			s. d.	
ABERCARNE and NEWBRIDGE, near Newport, Monmouthshire	Sir B. Hall, Bart.	Quartz and siliceous grains, moderately fine, with argillo-siliceous cement; micaceous, and with remains of fossil plants	Dark bluish grey.	167 15	1 to 10 tons, in thicknesses of 5 feet.	4½d., or 5s. per ton	1 5	Old churches and modern buildings in vicinity; new Docks at Newport and Cardiff.
BALL CROSS	- -	Siliceous grains with argillo-siliceous cement; occasionally micaceous, ferruginous.	Ferruginous brown striped, and zoned in deeper tints.	- -	- -	- -	- -	At Chatsworth and Bakewell.
BARBADOES, Tintern, Monmouthshire.	Duke of Beaufort.	Fine and coarse quartz, and other siliceous grains, with argillo-siliceous cement, ferruginous spots, and plates of mica.	Light greyish brown.	146 12	1 to 10 tons, thickest bed 10 to 12 ft.	10d. to 1s.	- -	Tintern Abbey.
BINNIE, Uphall, and in Linlithgowshire.	Earl of Buchanan.	Fine quartz grains, with argillo-siliceous cement, micaceous, chiefly in planes of beds.	Brownish grey.	140 1	Bands 14 to 18 ft. thick (3 in number).	1s. 1d. to 2s. for largest blocks.	2 9 to 3 8	New club-house in Prince's Street, Edinburgh, and numerous private houses there and in Glasgow.
BOLTON'S QUARRY, Aislaby, Yorkshire.	Messrs. Elgie and Lawson, as executors of the late Mr. Noble, of York.	Moderately fine siliceous grains, with argillo-siliceous cement, plates of mica, and spots of carbon disseminated.	Warm light brown.	126 11	100 ft. cube; top beds for house building, bottom beds for docks. Beds 3 to 8 ft. thick.	10d. to 1s.	1 9 to 2 1	Whitby Abbey, New University Library at Cambridge, Scarborough and Bridlington Piers, Sheerness and St. Katharine's Docks, &c.
BRAMLEY FALL (Old Quarry), near Leeds, Yorkshire.	Earl of Cardigan.	Quartz grains (often coarse), and decomposed felspar, with argillo-siliceous cement. Mica rare. Small ferruginous spots disseminated.	Light ferruginous brown.	142 3	Up to 18 tons.	- -	- -	In numerous bridges, waterworks, &c.
CALVERLEY, Tunbridge Wells, Kent.	John Ward, Esq., Holwood Park, Bromley, Kent.	Fine siliceous grains, with a slightly calcareous cement.	Variegated browns.	118 1	70 or 80 ft., and upwards to 500. Beds to 3½ ft.	4d. to 6d.	1 2 to 1 4	Upper part of new church at Tunbridge Wells; Catholic Chapel, the Calverley Hotel, new Market House, and Victoria National School, and about 100 houses, &c., at Tunbridge Wells and its vicinity.

SANDSTONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.			s. d.	
CRAIGLEITH, Craigleith Hill, near Edinburgh.	W. R. Ramsay, Esq., of Barnton.	Fine quartz grains, with a siliceous cement, slightly calcareous, occasional plates of mica.	Whitish grey.	145 14	Any practicable length and breadth, from 6 in. to 10 ft. thick.	9*d.* to 2*s.* 6*d.*, according to quality.	1 10½ to 3 7½	Used extensively in public buildings in Edinburgh; the College (1580), Registry (1774), courts of law, Custom House, Royal Exchange, National Monument, and numerous churches, and now using for repairs at Blackfriars Bridge.
CRAWBANK, Borrowstones, Linlithgowshire.	Duke of Hamilton.	Fine quartzose grains, with an argillo-siliceous cement, somewhat ferruginous; disseminated mica.	Light ferruginous brown.	129 2	5 ft. thick, 6 ft. broad; 10 ft. long.	1*s.* for blocks of not more than 5 cubic ft.	2 2	A Roman bridge (A. D. 140.), old church of Kinneil, of the twelfth century.
DUFFIELD BANK, Duffield, Derbyshire.	Mrs. Strathan.	Quartz grains of moderate size, and decomposed felspar, with an argillo-siliceous cement, ferruginous spots, and occasionally plates of mica.	Light brown with dark brown and purplish tints.	132 14	150 ft.; thickest beds about 4 ft.; half the depth brown, half white.	1*s.* 1*d.* the white stone, 9*d.* the brown stone.	- -	St. Mary's Bridge, Reporter Office, Mechanics' Lecture Hall, and Bishop Ryder's Church now building (Derby); also Duffield Bridge and chimney shafts to Grammar School, Birmingham.
DUKE'S QUARRIES, Holt Stanwell Bridge, Derbyshire.	Duke of Devonshire.	Quartz grains, generally coarse, with decomposed felspar, and an argillo-siliceous cement; ferruginous spots.	Red, varied with green, brown, and grey.	144 8	- -	7*d.*	2 8	Penitentiary at Millbank, and the filling in parts of Waterloo Bridge, London.
ELLAND EDGE, near Halifax, Yorkshire.	- -	Fine quartz grains, with an argillo-siliceous cement, micaceous in planes of beds.	Light grey brown.	153 4				
GATHERLEY MOOR, near Richmond, Yorkshire.	John Warton, Esq. Gisborough.	Quartz grains of moderate size, and an argillo-siliceous cement; ferruginous spots and plates of mica.	Cream.	135 13	1 to 3 tons, a bed 12 ft. deep.	8*d.* for the 12 ft. bed.	2 1	Aste Hall near Richmond, and Caterick bridges over the Swale; Purse Bridge over the Tees; Skelton Castle, Darlington Town Hall, Lockburn Hall, and numerous modern buildings.

SANDSTONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Blocks of the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot delivered in London.	Where used.
				lb. oz.		s. d.	s. d.	
GATTON, Gatton, Surrey.	Lord Monson.	Fine siliceous grains, with a calcareo-siliceous cement, containing green silicate of iron and plates of mica.	Greenish light brown.	103 1	35 to 60 ft. cube, from 4 to 10 ft. long.	1 4 to 1 6	- -	Hampton Court and Windsor Castle, &c.; many churches in Surrey; Town Hall and Almshouse Establishment at Croydon; and several modern buildings in the parish of Gatton.
GLAMMIS, Forfarshire.	Earl of Strathmore's trustees.	Siliceous grains of moderate size; cement slightly calcareous; mica abundant in planes of beds.	Purple grey.	161 2	Any practicable size; thickest bed 6 ft.	0 7 to 1 0	about 19s. per ton.	Glammis Castle and Inverquharity Castle, supposed of the tenth century; Cortachy Castle; and in modern buildings; Lendertis House, &c.
HEDDON, near Newcastle, Northumberland.	Mrs. Bewick, near Newcastle upon Tyne.	Coarse quartz grains, and decomposed felspar, with an argillo-siliceous cement, ferruginous spots.	Light brown ochre.	130 11	Beds 4 to 12 ft. thick.	0 6 to 0 10	1 8 to 2 0	Church at Heddon, steeple, 1764; Norman chancel; columns of portico to theatre, and Grey Monument at Newcastle; and nearly all the buildings, ancient and modern, in and about Newcastle.
HOLLINGTON, Staffordshire.	Sir J. Gibbons, Bart., near Staines, Middlesex.	Quartz grains of moderate size, with an argillo-siliceous cement; plates of mica.	Light brownish grey.	133 1	30 to 40 ft. square, and 8 ft. thick.	0 7 to 1 0	2 6	Trentham Hall, Drayton Manor, Heathhouse, and various public and private buildings in Staffordshire; Town Hall, Derby; Mear Hall, Cheshire, &c.
HUMBIE, Humbie, Linlithgowshire.	Earl of Hopetoun.	Fine quartz grains, with siliceous cement; slightly calcareous; mica chiefly in planes of beds.	Pale grey and light brown.	White 140 3 grey 135 13	90 cubic ft. and upwards, if required; thickest bed 8 ft.	1 0 to 1 10	2 6 to 3 2	Newliston House, Kirkliston; Dundas Castle; additions to the Royal Institution; front of Surgeons' Hall, spire of Tron Church, and various other public buildings in Edinburgh; also in Glasgow.
LONGANNET, near Kincardine, in Perthshire.	Trustees of late Lord Keith.	Fine quartz grains, with siliceous cement, containing oxide of iron; a few plates of mica.	Light ferruginous brown.	131 11	4 to 5 tons; thickest beds 5 ft.	0 8 to 2 6	1 8 to 3 6	Staadt House, Amsterdam; Exchange, Edinburgh; Tulle Mare Castle, Perthshire; and part of a street in Perth.

MUNLOCHY, in Ross-shire.	John Matheson, Esq., of Bennetsfield.	Fine siliceous grains, with an argillo-siliceous cement; micaceous.	Red and variegated.	160 9	Of large size; beds 2½ to 6 ft. thick.	0 5 to 0 5½	- -	Cathedral Church of Ross at Fortrose, A.D. 1124; Inverness Old Bridge, Cromwell Court, &c.
MYLNEFIELD, or RINGOODIE, near Dundee, in Perthshire.	James Mylne, Esq.	Fine siliceous grains, with a calcareo-argillo-siliceous cement; micaceous in planes of beds.	Purplish grey.	160 0	Any practicable size.	0 9 to 1 5	- -	Old steeple of Dundee, 12th century, well preserved; Royal Asylum of Dundee, &c.; Bell Rock Lighthouse, Royal Asylum of Perth, Kinfauns Castle, Castle Huntley, &c. &c.
PARK SPRING, near Leeds, Yorkshire.	Earl of Cardigan.	Fine quartz grains, and decomposed felspar, with an argillo-siliceous cement; mica chiefly in planes of beds.	Light ferruginous brown.	151 1	10 to 12 ft. long; thickest bed 2 ft. 4 in.	0 7	2 1½ to 2 5	Commercial buildings at Leeds, from the old quarry, which is of exactly similar stone to that of this quarry.
PENSHER, near Houghton-le-Spring, Durham.	Marquess of Londonderry.	Coarse quartz grains, with an argillo-siliceous cement; plates of mica.	Pale whitish brown.	134 5	Any practicable size; thickest bed 20 ft.	0 8¾	1 7	Pensher Chapel; Scotch Church, Sunderland; Sunderland Pier, Seaham Harbour, Victoria Bridge, on the Wear, &c.
PYOTDYKES, near Dundee, Forfarshire.	Alexander Clayhills, Esq., Innergowrie.	Siliceous grains of moderate size, with a calcareo-argillo-siliceous cement; micaceous.	Purplish grey.	162 8	Thickest bed 3 to 4 ft.	0 10 to 1 2	2 1 to 2 5	Extensively for the works at Dundee Harbour, &c.
SCOTGATE HEAD, Huddersfield, Yorkshire.	The freeholders of Onley.	Quartz grains, of moderate size, with an argillo-siliceous cement; mica in planes of beds, and occasional specks of carbon.	Light greenish grey.	158 0	Thickest bed 3 ft. 6 in.	0 8	1 2	York Castle; Bath Hotel, at Huddersfield.
STANCLIFF, or DARLEY DALE, near Bakewell, Derbyshire.	A. H. Heathcote, Esq., Blackwell.	Quartz grains of moderate size, and decomposed felspar, with an argillo-siliceous cement, ferruginous spots, and plates of mica.	Light ferruginous brown.	148 3	Of very large size.	1 5	3 3	Abbey in Darley Dale; Stancliff Hall, Birmingham; Grammar School, Birmingham; and Nottingham Railway Station Houses.
STENTON, near Barnard Castle, Durham.	Duke of Cleveland.	Fine quartz grains, and decomposed felspar, with an argillo-siliceous cement, ferruginous specks, and some plates of mica.	Ferruginous light brown.	142 8	15 to 20 ft. long, 2 ft. to 8 ft. in thickness.	0 5½	1 5	The Round Keep of Barnard Castle; Joint Stock Bank, and Market House, Barnard Castle.

BATH LODGE HILL, Combe Down, near Bath, Somersetshire.	W. V. Jenkins, Esq., Combe Grove House, Bath.	Chiefly carbonate of lime, in oolitic grains.	Cream.	116 00	12 to 96 ft. cube. Thickest bed, 4½ ft.	0 6	- -	Restoration of Henry VII.'s chapel, twenty years since. Kennet and Avon Canal, and other works.
BATH BAYNTON Quarry, Box, near Chippenham.	Thomas Strong, of Box, near Chippenham.	Chiefly carbonate of lime, in moderately fine oolitic grains, with fragments of shells (weather bed).	Cream.	123 00	Up to 10 tons. Thickest bed, 5 ft.	0 7	1 11	Laycock Abbey, Longleat, Bowood, south front of Wilton House, Windsor Castle, &c.
BATH (DREWE'S QUARRY), Monkton Farleigh, near Bath.	Wade Brown, Esq., Monkton Farleigh.	Chiefly carbonate of lime, in oolitic grains of moderate size.	Cream.	122 10	120 to 125 ft. Several beds, the deepest about 4 ft. 2 in. thick.	0 6	1 10	Buckingham New Palace; St. James's Square, Bath.
CRANMORE, near Doulting, Wiltshire.	- -	Carbonate of lime, with a few oolitic grains, and an abundance of small shells, commonly in fragments, often crystalline.	Light brown.	134 4	Of large size. The thickest beds will work 20 in.	0 7	- -	Cathedral of Wells, Glastonbury Abbey, &c.
HAYDOR, near Grantham, Lincolnshire.	John Archer Houblon, Esq., near Bishop's Stortford.	Carbonate of lime, with oolitic grains, often crystalline.	Brownish cream.	133 7	14 ft. × 3 ft. × 4 ft.	0 8	2 4	Lincoln Cathedral, Boston Church, Grantham Church, Newark Church, and most of the churches in the neighbourhood, and in the lower part of Lincolnshire; Culverthorpe House, Belvoir Castle, &c.
KETTON, in Rutlandshire, near Stamford.	Lord Northwick.	Oolitic grains of moderate size, slightly cemented by carbonate of lime.	Dark cream colour.	128 5	Up to 100 ft., beds vary very much: one 3 ft. 6 in. thick, called rag.	1 9	3 4	Cambridge, Bedford, Bury St. Edmund's, Stamford, London, &c.; many of the ancient and modern buildings at Cambridge; also in the modern works of Peterborough and Ely Cathedral, and at St. Dunstan's New Church, in London.
PORTLAND (TRADE QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.

OOLITIC STONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the largest procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.		s. d.	s. d.	
PORTLAND (KING BARROW EAST END QUARRY) adjoining WAYCROFT, Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (VERN-STREET QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	134 10 top bed.	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (CASTLE'S QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (WAYCROFT QUARRIES), Island of Portland.	The Crown, on lease to Messrs. Stewards and Co.	Oolitic carbonate of lime, with disseminated fragments of shells.	Whitish brown.	135 8 top bed.	Any practicable size.	1 4½	2 3	Goldsmiths' Hall, Reform Club House, and other public buildings in London.
PORTLAND (MAGGOTT QUARRY).	The Crown, on lease to Messrs. Stewards and Co.	Oolitic carbonate of lime, with fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 2	Various public buildings in London.
PORTLAND (GOSLING'S QUARRY).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with fragments of shells.	Whitish brown.	126 13 Roach	Any practicable size.	1 4½	2 3	Several public buildings in London.
PORTLAND (GROVE QUARRY BEVERS).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with numerous fragments of shells.	Whitish brown.	147 10 best bed. 145 9 carf.	Any practicable size.	1 4½	2 3	St. Paul's Cathedral, and several churches in London, built during the reign of Queen Anne.
PORTLAND (GROVE QUARRY, REDCROFT).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 0	St. Paul's Cathedral, and many churches in London, of Queen Anne's reign.

Of the Portland stones, it is to be observed generally, that the dirt bed is full of fossil roots, trunks, and branches of trees, in the position of their former growth. The top cap is a white, hard, and closely compacted limestone. The skull cap is irregular in texture, and is a well-compacted limestone. The roach beds are always incorporated with the freestone beds, that invariably lie below them, and are full of cavities formed by the moulds of shells and the like. The top bed is the best stone, the bottom one ill cemented, and will not stand the weather. A middle or curf bed occurs only in the southernmost quarries on the east cliff: it is soft to the north, and hard to the south. The good workable stone in the east cliff quarries is generally less in depth than in the same bed in the west cliff quarries, but the east cliff stone is harder, more especially to the south of the island. The stone, even in the same quarries, varies considerably. That which contains flints will not stand the weather. The bottom bed on the west cliff is not a durable stone, though sold as a good stone in the London market. The best stone is in the north-eastern part of the island; the worst in the south-western part. The annual consumption of the whole of the quarries in the island is equal to an area of one acre of the good workable stone, or about 24,000 tons. The entire area unworked is about 2000 acres. There are 56 quarries in the island, and about 240 quarrymen employed, of which number Messrs. Stewards employ usually about 138. (See Subsection 1666*f. et seq.*)

OOLITIC STONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.		*s. d.*	*s. d.*	
Taynton, or Teynton, near Burford, Oxon.	Lord Dynevor.	Carbonate of lime, partly oolitic and friable, with very small fragments of shells, irregularly laminated.	Streaky brown.	135 15	Any practicable size. Thickest bed, about 7 ft.	0 10 to 1 0	2 4	Blenheim, Cornbury Park, Barrington Park, the interior of St. Paul's and many other churches in London and Oxford, and in various bridges in Oxfordshire.
Wass, near Thirsk, Yorkshire.	Martin Stapleton, Esq.	Compact carbonate of lime, with oolitic grains and an argillo-calcareous cement; carbon disseminated.	Brown.	141 11 soft. 162 8 hard.	Beds variable, about 16 in.	- -	- -	West front and a large proportion of Byland Abbey.
Windrush, near Burford, Gloucestershire.	Lord Shelburne.	Fine oolitic grains, with calcareous cement, and a few fragments of shells.	Cream.	118 2 soft. 135 15 hard.	5 to 40 ft. Thickest bed, 2 ft. 6 in.	0 8	2 7	Windrush Church, Barrington House, and all the old buildings within many miles of the quarry.

1605. The following very useful enumeration of the stones used in buildings of the island, arranged under that head, and divided into the sorts of stone employed in them, we add, *verbatim*, from the Report which we have so much used. The heads are under Sandstone buildings, Limestone buildings, and Magnesian Limestone buildings.

SANDSTONE BUILDINGS.

Bakewell, Derbyshire. The houses generally are of sandstone, and in fair condition. A new bank now erecting of sandstone from Bakewell Edge.

Bakewell Church (14th century), of a sandstone of the vicinity, very much decomposed.

Barnard Castle, Durham (14th century). Circular keep, apparently of Stenton stone, in excellent condition. In modern works, the Joint Stock Bank and Market-house of Stenton stone, in good condition.

Belper New Church, Derbyshire. Built 10 years since, of sandstone from Hungerhill, in an incipient state (in parts) of decomposition.

Blandford Parish Church, Dorsetshire (1769). Of a green siliceous fine-grained sandstone, the dressings being of a stone similar to the Portland oolite; the former much decomposed; the latter in very good condition. Town Hall, about 80 years old, of stone similar to the Portland oolite, in good condition.

Brancepeth Castle, Durham. Of ancient date, of sandstone of the vicinity; recently restored extensively; older parts in various states of decomposition.

Briavel's, St., Castle, Glocestershire. In ruins (13th or 14th century). Entrance gateway (the chief remains of the castle) built of red sandstone, decomposed.

Bristol Cathedral (13th and 14th centuries). Built of red sandstone and a yellow limestone (magnesian?) strangely intermixed; the red sandstone in all cases decomposed, the limestone more rarely decayed; the tracery, &c. of the windows, which are of the limestone, are in good condition; but the pinnacles and other dressings, which are of the same material, are much decomposed. The east end of the cathedral is a remarkable instance of the decay and preservation of the two stones employed. Norman gateway, west of the cathedral (the upper part of the 15th century); the Norman archway and its enrichments, which are of a very florid character, built of yellow limestone (magnesian?), in excellent condition.

Byland Abbey (12th century). In part of a siliceous grit (principally in the interior), and in part (chiefly on the exterior) of a compact oolite, from the Wass quarries in the

vicinity. The west front, which is of the oolite, is in perfect condition, even in the dog's-teeth and other florid decorations of the doorways, &c. This building is *covered generally* with lichens.

CARLISLE. Ancient buildings: Cathedral (13th century), of red sandstone, in various states of decomposition. Modern buildings: Many of red sandstone, more or less in a state of decomposition.

CASTLE HOWARD, Yorkshire. Built generally of a siliceous fine-grained sandstone from the park; generally in good condition, but in some parts, such as the parapets, cupolas, and chimney shafts, much decomposed. The pilasters of the north front from a quarry at Appleton; in good condition, except where subjected to alternations of wet and dry, as in the plinths, where there are signs of decomposition. The stables are of Appleton stone, and in good condition.

CHATSWORTH HOUSE, Derbyshire. Original house built of Bell Crop sandstone from Bakewell Edge, not in very good condition, particularly in the lower parts of the building. In the recent additions the same stone is employed, together with that of Bailey Moor and Lindrop Hill.

CHEPSTOW CASTLE, Monmouthshire (11th and 12th centuries, with additions of the 14th century). Of mountain limestone and old red sandstone; the former in good condition; the latter decomposed. Dressings of doors, windows, archways, and quoins are for the most part of magnesian limestone, in perfect condition; the remainder is of red sandstone, and is generally much decomposed. Chapel (of the 12th century); mouldings and carvings of the windows, &c., which are of magnesian limestone, are in perfect condition.

COXWOLD CHURCH, Yorkshire (15th century). Generally of fine siliceous grit of the vicinity, and in part of a calcareous nature. Tower in good condition; porch decomposed; lichens abundant on the north side.

DERBY. St. Peter's Church (13th century), of the variegated coarse sandstone of the vicinity, similar to that of Little Eaton. The whole in bad condition; but the red stones less so than the grey or white. St. Almund's Church (of the 14th century), of a coarse sandstone of the vicinity, in a very decomposed state, to the obliteration of the mouldings and other details; it has lately been scraped and painted, to preserve it from further destruction. All Saints Church (tower of the 15th century), of sandstone, similar to that of Duffield Bank, partly in fair condition, and partly much decomposed, particularly the great western entrance. The body of the church, built 110 years since, of sandstone, in part decomposing. Modern buildings: Town Hall, of sandstone from Morley Moor, built a few years since, in very good condition.

DURHAM CATHEDRAL (11th and 12th centuries). Of a sandstone of the vicinity, elected indiscriminately, and in all stages of decomposition; few stones are quite perfect. CASTLE (of the 11th century). Of similar stone, and in a similar state.

EASBY ABBEY, Yorkshire (13th and 14th centuries). Of sandstone of the vicinity; mouldings and carvings decomposed and in part obliterated. Walls built very rudely, and in various states of decomposition; some parts, however, maintain their original surface.

ECCLESTON ABBEY, Yorkshire (13th century). Of stone similar to that of the Stenton quarry. The mouldings and other decorations, such even as the dog's-teeth enrichments, are in perfect condition.

EDINBURGH. Ancient buildings: Holyrood Chapel (12th century), of sandstone from the vicinity, in part much decomposed; in other parts, such as the west door, almost perfect. The palace (built in the 16th and 17th centuries) of similar stone, generally in good condition, the older parts being slightly decomposed. The oldest part of the Tron Church (1641), of sandstone, much decomposed. A house on the Castle Hill (1591), of sandstone, only slightly decomposed.

Modern buildings, wholly erected of sandstones from the Cragleith, Red Hall, Humbie, and Binnie quarries, for the most from the first-mentioned quarry. None of them exhibit any appearance of decomposition, with the exception of ferruginous stains, which are produced upon some stones. Among the oldest is the Registry Office, which is of Cragleith stone, and built above sixty years since; it is in a perfect state.

FOUNTAIN'S ABBEY, Yorkshire (11th and 12th centuries, with additions of the 16th century). Of coarse sandstone of the vicinity, generally in bad condition, particularly the west front, which is much decomposed. The nave and transept, which are the earliest portions of the building, are the best preserved.

FOUNTAIN'S HALL, Yorkshire (1677). Of sandstone of the vicinity, and magnesian limestone in the dressings. The whole in fair condition.

FOREST OF DEAN, Gloucestershire. Park End new church, built fifteen years since, of sandstone, similar to that of Colford. No appearance of decomposition.

Glasgow. Ancient buildings: High Church (12th century), sandstone of the vicinity, generally very much decomposed, particularly on the south side Old quadrangle of the College (James II.), of sandstone, decomposed.

Modern buildings: Hunterian Museum (1804); superstructure said to be of stone from the President quarry; slight traces of decomposition on the south-west front. The basement of another sandstone, in a more advanced state of decomposition; other parts of the building are in an almost perfect state. The other buildings are generally erected of stone from the Giffneuch and other quarries in the immediate neighbourhood, except the new Exchange buildings, which are of stone from the Humbie quarry, thirty miles from Glasgow, recently erected, in which there are not any apparent symptoms of decomposition.

Gloucester Cathedral (Norman for the greater part, altered and cased in the 15th century), built of a fine-grained and ill-cemented oolite, a shelly oolite, and a red sandstone (north side) intermixed, of which the former constitutes the greater portion. The tower (15th century), of shelly oolite, in perfect condition. The early turrets of the south transepts are also in good condition. The body of the building is much decomposed. The great cloister is built of the same materials as the cathedral. The moulded and decorated work is in good condition, the other parts are more or less decomposed. The small cloister is built of a fine oolite with a compact cement, and is in good condition. The New Bridge, of Whitchurch sandstone, parapets of Ruordean fine-grained sandstone, in good condition.

Haddon Hall, Derbyshire (15th and 16th centuries). Of a fine-grained sandstone, similar to that of Lindrop Hill. The dressings, parapets, chimney shafts, quoins, &c. are wrought and rubbed; the remainder of the walls is of rough walling. The whole in fair condition.

Harrowgate. Cheltenham Pump Room, of sandstone from Woodhouse, near Leeds. Built recently. In good condition. Swan Hotel and other modern buildings, of a coarse sandstone of the vicinity; generally in good condition.

Hardwicke Hall, Derbyshire. (1597). Of a fine-grained sandstone, chiefly from a quarry in the hill on which the house is built, intermixed with a calciferous grit, similar to that of Mansfield; generally in good condition. The ashler is in parts decomposed, especially where it is set on edge.

Howden Church, Yorkshire (15th century); partly of magnesian limestone, of a deep yellow colour, and partly of a coarse siliceous grit, of a ferruginous colour. Dressings and enrichments and the central tower are of the former stone; generally decomposed, particularly at the top of the tower. The other parts of the building, which are of the grit, are very much decomposed.

Kirkstall Abbey, Yorkshire (11th century). Of coarse sandstone of the vicinity, in various stages of decomposition according to the aspect. The east side is in fair condition; some of the zig-zag enrichments and early capitals and other enrichments of mouldings are in perfect condition. The windows of the chancel and tower (inserted in the 16th century) of a yellow sandstone, are for the most part gone, and what remains is much decomposed.

Mansfield TownHall, Nottinghamshire. Built three years since, of magnesio-calciferous sandstone from Mansfield: no appearance of decomposition.

Newcastle-upon-Tyne. Ancient buildings: St. Nicholas' Church (14th century), of sandstone of the vicinity, similar to that of the Heddon Quarry, very much decomposed. Parts restored within the last century, with the same stone, now decomposing. The upper part of the tower and spire restored within the last five years, and painted to preserve the stone from decay. Other ancient buildings, of the same stone, more or less in a state of decomposition, according to the date of their erection.

Modern buildings, built within the last 25 years, of sandstone from the Felling and Church quarries at Gateshead and the Kenton quarry: parts already show symptoms of decomposition.

Pontefract Castle, Yorkshire (14th century). Built generally of a coarse grit, of a dark brown colour, occasionally mixed with an inferior magnesian limestone. The whole in a very decomposed state, more particularly the sandstone, in which all traces of the original surface are effaced. Fragments of magnesian limestone are embedded in several parts of the walls, with mouldings of the 12th century, in perfect condition.

Raby Castle, Durham (14th century). Of sandstone of the vicinity: parts in a perfect state, others slightly decomposed.

Richmond Castle, Yorkshire (11th century). The keep, of sandstone, similar to that of Gatherly Moor, generally in good condition; mouldings and carvings in columns of window in a perfect state.

Ripon, Yorkshire. An obelisk in the market-place (1781), of coarse sandstone, much decomposed in laminations parallel to the exposed faces.

RIPON CATHEDRAL. Lower part, east end, and south-east angle (Norman), of coarse sandstone of the vicinity, in good condition. The west front, the transepts, and tower (of the 12th and 13th centuries), of the coarse sandstone of the vicinity, in fair condition. The mouldings, although generally decomposed, are not effaced. The dog's-teeth ornaments in most parts nearly perfect. The aisles of the naves, the clerestory, and the choir (of the 14th and 15th centuries), of coarse sandstone and magnesian limestone intermixed, not in good condition; the latter stone, on the south side, often in fair condition. The lower parts of the building generally, but particularly the west fronts, which are of coarse sandstone, are very much decomposed.

RIVAULX ABBEY, Yorkshire (12th century). Of a sandstone at Hollands, one mile from the ruins; generally in excellent condition. West front slightly decomposed; south front remarkably perfect, even to the preservation of the original toolmarks.

SHAFTESBURY, Dorsetshire. St. Peter's Church (15th century). Of a green siliceous sandstone, from quarries half a mile south of the church. The whole building much decomposed. The tower is bound together by iron, and is unsafe, owing to the inferior quality of the stone.

SPOFFORTH CASTLE, Yorkshire (14th century). Of coarse red sandstone; more or less, but generally much, decomposed. The dressings of the windows and doors, of a semi-crystalline magnesian limestone, are in perfect state, the mouldings and enrichments being exquisitely sharp and beautiful.

TINTERN ABBEY (13th century). Considerable remains of red and grey sandstones of the vicinity, in part laminated. In unequal condition, but for the most part in perfect condition; covered with grey and green lichens.

TISBURY CHURCH (13th and 14th centuries; the lower part of the tower of the 12th century). Of calciferous limestone from Tisbury. The dressings are composed of stone throughout, in perfect condition. The ashlar variable; in part much decomposed; the undecomposed portions are covered with lichens. Tombstones in the churchyard generally in good condition, some being more than a century old. The houses of the village built generally of the Tisbury stone, and are in very good condition. The whole covered with lichens.

WAKEFIELD PARISH CHURCH, Yorkshire (tower and spire of the 16th century). Of sandstone, much decomposed. The body of the church, of recent date, of sandstone strongly laminated, and generally decomposed between the laminæ.

WHITBY ABBEY (13th century). Of stone similar to that of Aislaby Brow, in the vicinity; generally in good condition, with the exception of the west front, which is very much decomposed. The stone used is of two colours, brown and white; the former, in all cases, more decomposed than the latter. The dog's-teeth and other enrichments in the east front are in good condition.

LIMESTONE BUILDINGS.

BATH. Abbey church (1576), built of an oolite in the vicinity. The tower is in fair condition. The body of the church, in the upper part of the south and west sides, much decomposed. The lower parts, formerly in contact with buildings, are in a more perfect state; the reliefs in the west front of Jacob's ladder are in parts nearly effaced. Queen's Square, north side, and the obelisk in the centre, built above 100 years since, of an oolite with shells, in fair condition. Circus (built about 1750), of an oolite in the vicinity, generally in fair condition, except those portions which have a west and southern aspect, where the most exposed parts are decomposed. Crescent (built above 50 years since), of an oolite of the vicinity, generally in fair condition, except in a few places, where the stone appears to be of inferior quality.

BRISTOL CATHEDRAL (of the 13th and 14th centuries). Built of red sandstone and apparently a yellow limestone (magnesian?) strangely intermixed. The red sandstone in all cases decomposed; the limestone more rarely decayed. The tracery, &c. of the windows, which are of the limestone, are in good condition, but the pinnacles and dressings of the same material much decomposed. The east end of the cathedral is a remarkable instance of the decay and preservation of the two stones employed. Norman gateway, west of the cathedral (the upper part of the 15th century), the Norman archway and its enrichments, which are of a very florid character, built of yellow limestone (magnesian?), in excellent condition.

———, ST. MARY REDCLIFFE (tower of the 12th century; body of the church of the 15th century). Of oolitic limestone, from Dundry; very much decomposed.

BURLEIGH HOUSE (15th century). Of a shelly oolite (Barnack rag), in excellent condition throughout. The late additions are of Ketton stone.

BYLAND ABBEY, Yorkshire (12th century). In part of a siliceous grit (principally in the interior), and in part (chiefly on the exterior) of a compact oolite, from the Wass quarries in the vicinity. The west front, which is of the oolite, is in perfect condition,

even in the dog's-teeth and other florid decorations of the doorways, &c. This building is generally covered with lichens.

Colley Weston Church, Northamptonshire (14th century). Of a shelly oolite (Barnack rag), in perfect condition throughout.

Dorchester. St. Peter's Church (15th century). Of laminated oolite, somewhat similar to that of Portland, and of a shelly limestone, somewhat resembling that of Hamhill. The latter used in pinnacles, parapets, and dressings. The whole in a decomposed state.

Glastonbury — Abbey. Joseph of Arimathea's Chapel. Considerable ruins; Norman, of shelly limestone, similar to that of Doulting; generally in good condition; the zig-zag and other enrichments perfect; the capitals of the columns, corbels, &c. are of blue lias, much decomposed, and in some cases have disappeared. The *Church*. Considerable remains of the choir, and a small portion of the nave (11th century), of shelly limestone, similar to that of Doulting, in good condition. *St. Benedict's Parish Church* (14th century). Of limestone, similar to that of Doulting, in good condition. *St. John the Baptist's Parish Church* (15th century). Of stone similar to that of Doulting, generally in fair condition.

Glocester — Cathedral, (Norman for the greater part, altered and cased in the 15th century). Built of a fine-grained and ill-cemented oolite, a shelly oolite, and a red sandstone (north side) intermixed, the former constituting the greatest portion of the edifice. The tower (15th century), of shelly oolite, in perfect condition. The early turrets of the south transept are also in good condition. The body of the building is much decomposed. The great cloister is built of the same materials as the cathedral. The moulded and decorated work is in good condition; the other parts are more or less decomposed. The great cloister is built of a fine oolite, with a compact cement, and is in good condition. *St. Nicholas's Church* (body Norman; tower and spire, 15th century), of a shelly and inferior kind of oolite intermixed, and in unequal condition. *St. Michael's Church* (15th century), built of same stone as that of St. Nicholas, and in the same condition.

Grantham Church (13th century). Lofty tower and spire at the west end. Built of an oolite, similar to that of Ancaster, in good condition, more especially the tower, except as to some portions of the base mouldings.

Ketton Church, Rutlandshire. (West entrance door, Norman; tower of the 12th or 13th century; nave, aisles, and chancel of the 14th century). Of a shelly oolite (Barnack rag), in good condition. Dog's-teeth, carved corbels, and other enrichments in a perfect state.

Kettering Church (14th and 15th centuries). Of a shelly oolite, fine-grained, the greater portion resembling Barnack rag. The tower and spire in perfect condition. The body of the church in parts slightly decomposed.

Kirkham Priory, Yorkshire (13th century). Inconsiderable remains. The western front and great entrance slightly decomposed throughout; the portions which remain of the body of the church very perfect, but many of the stones are much decomposed. The stone is very similar to that of the Hildenly quarry. The whole is covered with lichens.

Lincoln Cathedral (the minster generally of the 12th and 13th centuries). Of oolitic and calcareous stone of the vicinity; generally in fair condition, more especially the early portions of the west front. The ashler and plain dressings of the south front are, however, much decomposed. The mouldings and carvings of the east front are in a perfect state. *Roman Gate*, of a ferruginous oolite, in fair condition. *The Castle Gateway* (13th century), of an oolitic limestone; ashler much decomposed, dressings perfect.

Melton Old Church, Yorkshire (12th century). Light semi-compact limestone, similar to that of the Hildenly quarry; generally in good condition, particularly the great west door (of the 11th century), where the zig-zag and other enrichments are perfect. Some stones are much decomposed.

Montacute, Somersetshire — Parish Church (15th century). Of Hamhill stone, in perfect condition, covered with lichens. The Abbey (15th century). Supposed abbot's house and gateway, of Hamhill stone, in good condition. *Montacute House* (17th century), of Hamhill stone, in excellent condition.

Martock Church, Somersetshire (15th century). Of a shelly ferruginous brown limestone from Hamhill, in good condition, except the plinth and base mouldings, which are much decomposed. Covered with lichens.

Newark Church (15th century; the tower, in part, of the 12th century). Of an oolite, similar to that of Ancaster; generally in fair condition, with the exception of parts of the base mouldings. The building is covered with a grey lichen. *The Castle* (Norman, with additions in the 15th century). Chiefly of sandstone of the vicinity: in unequal condition. A large portion of the dressings of the windows, &c. are of oolite.

probably from Ancaster. *Town Hall* (50 or 60 years old). Built of the Ancaster oolite; in good condition; in some blocks, however, there is an appearance of lamination, where decomposition has to a slight extent taken place.

OXFORD CATHEDRAL, Norman (12th century). Chiefly of a shelly oolite, similar to that of Taynton; Norman work in good condition, the latter work much decomposed. *Merton College Chapel* (13th century). Of a shelly oolite, resembling Taynton stone; in good condition generally. *New College Cloisters* (14th century). Of a shelly oolite (Taynton), in good condition. The whole of the colleges, churches, and other public buildings of Oxford, erected within the last three centuries, are of oolitic limestone from Heddington, about one mile and a half from the university, and are all, more or less, in a deplorable state of decomposition. The plinth, string-courses, and such portions of the buildings as are much exposed to the action of the atmosphere, are mostly of a shelly oolite from Taynton, fifteen miles from the university, and are universally in good condition.

PAUL'S, ST., CATHEDRAL, LONDON (finished about 1700). Built of Portland oolite, from the Grove quarries on the east cliff. The building generally in good condition, especially the north and east fronts. The carvings of flowers, fruit, and other ornaments are throughout nearly as perfect as when first executed, although much blackened; on the south and west fronts, larger portions of the stone may be observed of their natural colour than on the north and east fronts, occasioned by a very slight decomposition of the surface. The stone in the drum of the dome, and in the cupola above it, appears not to have been so well selected as the rest; nevertheless scarcely any appreciable decay has taken place in those parts.

PICKERING CHURCH, Yorkshire (13th and 14th centuries). Oolite rock of the neighbourhood; very much decomposed; the windows, mullions, and buttress angles obliterated.

PICKERING CASTLE (14th century). The walls of the oolite of the neighbourhood, and the quoins of a siliceous grit. The whole in fair condition.

PORTLAND, Dorsetshire — New Church (built 1766), of Portland oolite, fine roach; in a perfect state, still exhibiting the original tool marks. Wakeham Village, Tudor House, of Portland oolite, in excellent condition. *Old Church*, in ruins, near Bow and Arrow Castle (15th century), of Portland oolite, resembling top bed; in very good condition; original chisel marks still appear on the north front. *Bow and Arrow Castle.* Considerable remains of the keep, many centuries old, of Portland oolite; the ashlar resembles the top bed, and is in perfect condition; the quoins and corbels of the machicolated parapet appear to be of the cap bed of Portland oolite, and are in good condition.

SALISBURY CATHEDRAL (13th century). Of siliciferous limestone from Chillmark quarry. The entire building is in excellent condition, except the west front, which in parts is slightly decomposed. The building generally covered with lichens.

SANDYSFOOT CASTLE, near Weymouth (temp. Hen. VIII.). Considerable remains of keep, chiefly of Portland oolite, partly of the top bed and partly of the fine roach; generally in excellent condition, with the exception of a few and apparently inferior stones. The inside ashlar of the walls is of large-grained oolite, apparently from the immediate vicinity of the castle, much decomposed.

SOMERTON CHURCH, Somersetshire (14th century). Built chiefly of blue lias; the quoins, buttresses, parapets, and other dressings of a coarse ferruginous shelly limestone, in various stages of decay. The parapet of the clerestory of a lighter-coloured stone, in good condition.

STAMFORD — St. Mary's Church (13th century). Of a shelly oolite (Barnack rag), in fair condition. *St. John's Church* (14th century). Of similar stone, ill selected, and consequently decomposed in parts and in laminations, according to the direction of the beds of shells. *St. Martin's Church* (14th century). Of similar stone, in good condition. *All Saints* (lower part of the body of the church 13th century; the remainder 15th century). Tower and spire in fine condition; body of the church decomposed. *Standwell's Hotel*, built twenty-four years since of an oolite similar to that of Ketton; in perfect condition. *St. Michael's New Church.* Built four years since; no appearance of decomposition.

WELLS, THE CATHEDRAL. West front (13th century), upper part of tower (14th century), of shelly limestone, similar to that of Doulting, generally decomposed, but not to any great extent. North flank (porch and transept 13th century, the remainder of the 14th century), of similar stone, in good condition, except lower part of flank and west tower. The central tower (of the 14th century) in very good condition. South side of the cathedral generally in good condition. *Chapter House* (13th century, with additions of the 15th century). The whole in good condition excepting the west front of the gateway, which is decomposed. Close gates (15th century) much de-

composed, but especially on the south and south-west. The cloisters (15th century) generally decomposed, particularly the mullions and tracery.

Westminster Abbey (13th century). Built of several varieties of stone, similar to that of Gatton or Ryegate, which is much decomposed, and also of Caen stone, which is generally in bad condition; a considerable portion of the exterior, especially on the north side, has been restored at various periods, nevertheless abundant symptoms of decay are apparent. The cloisters, built of several kinds of stone, are in a very mouldering condition, except where they have been recently restored with Bath and Portland stones. The west towers, erected in the beginning of the 18th century with a shelly variety of Portland oolite, exhibit scarcely any appearance of decay. Henry the Seventh's Chapel, restored about twenty years since with Combe Down Bathstone, is already in a state of decomposition.

Windrush Church (15th century). Of an oolite from the immediate vicinity; in excellent condition. A Norman door on the north side, enriched with the bird's-beak and other characteristic ornaments, is in perfect condition. Tombstones in the churchyard, very highly enriched and bearing the dates of 1681, 1690, apparently of Windrush stone, are in perfect condition.

Wyke Church, Dorsetshire (15th century). Of oolite, similar to Portland, the whole in good condition, except the mullions, tracery, and dressings of doors and windows, which are constructed of a soft material, and are all decomposed. On the south side, the ashler is in part covered with rough-cast. The entire building is thickly covered with lichens.

MAGNESIAN LIMESTONE BUILDINGS.

Beverley, Yorkshire. The minster (12th, 13th, and 14th centuries), of magnesian limestone from Bramham Moor, and an oolite from Newbold; the former, which is used in the west tower, central tower, and more ancient parts of the minster, generally in good condition; but in other parts of the building the same material is decomposed. The Newbold stone, chiefly employed on the east side, is altogether in a bad condition. Some of the pinnacles are of Oulton sandstone, and are in bad condition. The building is partly covered with lichens. *St. Mary's Church* (14th century), now in course of restoration, of magnesian limestone and oolite, supposed to be from Bramham Moor and Newbold, respectively. The ancient parts are in a very crumbling state, even to the obliteration of many of the mouldings and enrichments.

Bolsover Castle, Derbyshire (1629). Mostly in ruins; of magnesian limestone of several varieties, and of a calcareous fine-grained sandstone. The dressings, which are generally of sandstone, are much decomposed, in some instances to the entire obliteration of the mouldings and other decorations, and to the destruction of the form of the columns, rustications, &c. Most of the string courses, a portion of the window dressings, and the ashler, which are of magnesian limestone, are generally in excellent condition.

Bolsover Church, Derbyshire (15th century). Of a magnesio-calciferous sandstone, more or less in a decomposed state throughout.

Chepstow Castle, Monmouthshire (11th and 12th centuries, with additions of the 14th century). Of mountain limestone and old red sandstone; the former in good condition, the latter decomposed. Dressings of door, window, archway, and quoins are for the most part of magnesian limestone, and in perfect condition. The remainder is of red sandstone, and is generally much decomposed. Chapel (of the 12th century), mouldings and carvings of windows, &c., which are of magnesian limestone, in perfect condition.

Doncaster (Old) Church (15th century). Of an inferior magnesian limestone, generally much decomposed, more especially in the tower, and on the south and west sides; now under general and extensive repair.

Hemingborough Church, Yorkshire (15th century). Of a white crystalline magnesian limestone. The entire building is in a perfect state, even the spire, where no traces of decay are apparent.

Howden Church, Yorkshire (15th century). Partly of magnesian limestone of a deep yellow colour, and partly of a coarse siliceous grit of a ferruginous colour. Dressings and enrichments, and the central tower, are of the former stone, generally decomposed, particularly at the top of the tower. The other parts of the edifice, built of the grit, are very much decomposed.

Huddlestone Hall, Yorkshire (15th century). Of semi-crystalline magnesian limestone from the neighbouring quarry. In excellent condition, even to the entire preservation of the mouldings of the chapel window in the south-west front. The outer gate piers in the fence wall, also of magnesian limestone, very much decomposed.

Knaresborough Castle, Yorkshire (12th century). Magnesian limestone, carious in part;

generally in very good condition, except on the south and south-west portions of the circular turrets, where the surface is much decomposed. The mouldings generally are in a perfect state. The joints of the masonry, which is executed with the greatest care, are remarkably close. The stone of the keep, which is of a deep brown colour, and much resembles sandstone, is in good condition, especially on the south-west side.

KONINGSBOROUGH CASTLE, Yorkshire (Norman). Coarse-grained and semi-crystalline magnesian limestone, from the hill eastward of the castle; in perfect condition. The masonry is executed with great care, the joints very close, but the mortar within them has disappeared.

RIPON CATHEDRAL. Lower part, east end, south-east angle (Norman), of coarse sandstone from the vicinity, in good condition. The west front, the transepts, and tower (of the 12th and 13th centuries), of coarse sandstone of the vicinity, in fair condition. The mouldings, although generally decomposed, are not effaced. The dog's-teeth ornament in most parts nearly perfect. The aisles of the nave, the clerestory, and the choir (of the 14th and 15th centuries), of coarse sandstone and magnesian limestone intermixed, not in good condition. The latter stone, on the south side, often in fair condition. The lower parts of the building generally, particularly the west fronts, which are of coarse sandstone, are much decomposed. An obelisk, in the market-place (1781), of coarse sandstone, is much decomposed, and in laminations parallel to the exposed faces.

ROBIN HOOD'S WELL, Yorkshire (1740). A rusticated building, of magnesian limestone, in perfect condition.

ROCHE ABBEY, Yorkshire (12th century). Inconsiderable remains, of semi-crystalline magnesian limestone from the neighbouring quarry, generally in fair condition. The mouldings and decorated portions are perfect. Gate-house (12th century) generally decomposed, with the exception of the dressings and mouldings, which are perfect.

SELBY CHURCH, Yorkshire (nave and lower part of the tower of the 11th century; the west front and aisles of the 12th century; and the choir with its aisles of the 14th century). The Norman portion of the building, which is of grey magnesian limestone, is in excellent condition, particularly the lower part. The early English portions of the building are also of magnesian limestone, and in a partially decomposed state. The later portions of the building, which also are of magnesian limestone, are much decomposed and blackened.

SOUTHWELL CHURCH, Notts (of the 10th century). Of magnesian limestone, similar to that of Bolsover Moor, in perfect condition. The mouldings and enrichments of the doorway appear as perfect as if just completed. The choir, which is of the 12th century, and built of a stone similar to that of Mansfield, is generally in good condition.

SPOFFORTH CASTLE, Yorkshire (14th century). Of coarse red sandstone, generally much decomposed. The dressings of the windows and doors, of a semi-crystalline magnesian limestone, are in a perfect state, the mouldings and enrichments being eminently sharp and beautiful.

STUDLEY PARK, Yorkshire. Banquetting house, about 100 years old, of yellowish magnesian limestone, in perfect condition.

THORPE ABBEY VILLAGE. The houses generally of this village are built of magnesian limestone from the vicinity; they are in excellent condition, and of a very pleasing colour.

THORPE SALVIN, near Worksop. Manor-house (15th century), in ruins. Of a siliciferous magnesian limestone and a sandstone, in unequal condition; the quoins and dressings are generally in a perfect state. *Parish Church* (15th century), also of a siliciferous variety of magnesian limestone and a sandstone, in unequal but generally fair condition. A Norman doorway under the porch is well preserved.

TICKHILL CHURCH, Yorkshire, (15th century). Of magnesian limestone, in excellent condition. The lower part of the tower (of the 12th century) also in fair condition.

YORK. *Ancient Buildings:* CATHEDRAL (transepts, 13th century; tower, nave, &c., 14th century). Of magnesian limestone, from Jackdaw Craig. West end and towers restored thirty years since; they are generally in fair condition, but some of the enriched gables and other decorations are obliterated. The transepts are in many places much decomposed, especially in the mouldings and enrichments. The central tower is generally in good condition, but several of the enriched parts are decomposed. *St. Mary's Abbey* (12th century), of magnesian limestone. West front of the church generally much decomposed; the north flank in better condition, but in parts much decomposed. The gateway, which is of Norman origin, is in fair condition. *Roman Multangular Tower.* Built of small stones; such as are of magnesian limestone are in good condition. *St. Denis's Church.* Norman doorway of magnesian

limestone; south side highly enriched with zig-zag and other ornaments; the column are gone; the parts which remain are in good condition. *St. Margaret's Church* (15t century), of magnesian limestone; east front much exposed, and in good condition The porch is of Norman date, and has been reconstructed; four bands of enrichmer in the head, in tolerably fair condition, but many stones, particularly those of a dec yellow brown colour, are much decomposed. *The other churches of York* (which ar of the 14th and 15th centuries) are built of magnesian limestone, and are generally i an extremely decomposed state; in many instances all architectural detail is obliterated *Modern Buildings:* The Museum, of Hackness sandstone, built nine years sinc much decomposed wherever it is subject to the alternation of wet and dry, as at th bottom of the columns of the portico, plinth, &c. The Castle (recently erected) the plinth of the boundary wall (which is of Bramleyfall sandstone) already exhibit traces of decomposition. *York Savings Bank.* Huddersfield stone (?), in goo condition.

Worksop Church (principally of the 13th century), of a siliciferous variety of magnesia limestone and of a sandstone; in very unequal condition. Some parts are very muc decomposed, whilst others are in a perfect state.

1666. In the above table the names of the quarries are inserted under the general di sions of the different species of stone, and the specimens were considered as fair averag samples of the workable stone in such quarries. The experiments were conducted b Messrs. Daniel and Wheatstone. As a conclusion to the report, it may be satisfactory t name the actual stones used in the construction of the first portions (1840) of the Hous of Parliament. The foundation was laid with Penryn granite, rising to the level of th ground, therefore but little seen. Above it is Fog-tor granite from Dartmoor. A smal portion only of the superstructure, to the top of the basement windows, was built with Bolsover Moor stone from near Chesterfield; after which Anston stone was used for the remainder of the outside works. In the interior, Painswick and Caen stones have been employed; St. Stephen's crypt is of Beer stone. It has been asserted that had Govern ment employed a supervision at the quarries to prevent imperfect blocks being sent up to London, the present unsightly appearance of many parts of the building would not have resulted.

1666*a*. In *par.* 1500 is already supplied tables of the *crushing weights* of many of the stones herein mentioned. Hereto is added a further table of the *weights* of a large number of building stones, taken from the one prepared by the late C. H. Smith for R. Hunt's *Mineral Statistics of the United Kingdom, &c.* Part II. for 1858, published 1860; it was also given in the *Transactions* of the Institute of British Architects, 1859-60.

1666*b*. TABLE OF THE WEIGHTS OF BUILDING STONES, (IN CONTINUATION).

Name of Quarry.	Post Towns.	Weight per cubic foot avoirdupois. lb.	oz.

Mumble	"	170	7

1666c. In the year 1858, the present editor contributed to the *Builder Journal* (pp. 632–3) a list of the *Building Stones used externally in and near the Metropolis*, with the names and dates of erection of the buildings in which they had been used. This list cannot be here inserted, but the following are the stones named:—Anston, Aubigny, Bargate, Bath, Bramley Fall, Broomhill, Cadeby, Caen, Chapel Town (near Leeds) rubble, Craigleith, Godstone, Great Barrington, Harehill, Kentish rag, Yorkshire stone (hammer-dressed face), Ketton, Portland, Prudholme or Prudham, Reigate, Roche Abbey, Sneaton rag (from Whitby), Steetley, Swanage or Purbeck, and Whitby (Egton Quarries) stones, besides Granite, and Flint; we consider it desirable, however, to notice a few of the leading stones now employed in London.

1666d. The North Anston stone of Yorkshire, not mentioned in the preceding *Report*, belongs to the magnesian limestone formation, and is of a yellowish brown colour. As examples of its use we point to the Museum of Practical Geology in Jermyn Street, Pall Mall, in the façades of which there is scarcely a bad stone to be seen. This well conceived structure was erected from the design of James Pennethorne during the years 1837 to 1848. At the New Hall and Library, Lincoln's Inn, designed 1843–45 by P. Hardwick, R.A., this stone is in a lamentable state of decay, occasioned (as is reported in the discussion on G. R. Burnell's paper, *On Building Stones, &c.*, read at the Society of Arts in 1860), by the use of two particular beds, the blocks of which were in a state of decay before they left the quarry, and supposed to have been selected by the builder as yielding him the best profit. The labour upon Anston stone is intermediate between Yorkshire and Portland stones; it can be obtained of any required dimensions. The office of the Amicable Life Assurance Company, in Fleet Street, was erected 1843, with the Mansfield Woodhouse or Bolsover stone, in the façade of which there is scarcely any trace of decay.

1666e. From the Mansfield quarries are now sent up the red Mansfield stone, the white Mansfield stone, and the yellow magnesian or Bolsover limestone. The former is much introduced for colonnettes, short shafts, and bands in coloured coursed ashlar work. For similar decorative work, the following stones have been used (1865) at the new offices of the Crown Assurance Company in Fleet Street; namely, Portland stone in the piers and caps; Forest of Dean, red Mansfield, and blue Warwick, in other portions of the front; and Sicilian marble over the arches.

1666f. In consequence of the reintroduction of Portland stone of late years, we would refer, in addition to what has been stated on p. 467, as to the quarries of Portland stone, to the article *Lithology*, written by the late C. H. Smith, and published in the *Transactions* of the Institute of British Architects, 1842. Also to a report, published in the *Builder* of 1863, p. 859, by F. A. Abel, being the result of his examination into the comparative qualities and fitness for building purposes, of samples of stone from different quarries, and made under the direction of the Inspector General of Fortifications.

1666g. These results "show that all the superior descriptions of 'whit bed' stone combine strength and compactness in a considerably higher degree than the varieties of 'base-bed' stone. Some kinds of the 'whit-bed' stone, however (i.e. those from the New Maggot and Inmosthay quarries), though ranking with the best as regards strength, exhibit a greater degree of porosity. Again, other 'whit-bed' stones (from Old Maggot, Waycroft, and Independent quarries) exhibit but little superiority, in point either of strength or compactness, over the generality of the 'base-bed' stones, and are, indeed, inferior to the best 'base-bed' variety."

1666h. "The 'base-bed' stones are, undoubtedly, more generally uniform in structure than those of the 'whit-bed;' this being mainly due to the comparative freedom of the former from distinct petrifactions. Though such petrifactions were shown, by the results of experiments, to impart, in many instances, great additional strength to the stone, they frequently give rise by their existence to cavities sometimes of considerable size, which not only serve to weaken those particular portions of the stone, but may also, if they exist in proximity to exposed surfaces of a block of stone, promote its partial disintegration by the action of frost. Greater care is, therefore, unquestionably required in the selection of 'whit-bed' stone than need be employed in the case of all the better varieties of 'base-bed' stone." The results of my experiments lead me to the following conclusions regarding the comparative merits of the various descriptions of Portland stone in question, for building purposes:—

"For *External* work, in the order of their merit:—I. Stone from War Department quarry, Verr Hill; and 'whit-bed' stone, Admiralty quarry.

II. 'Whit-bed' stone, New Maggot quarry; 'base-bed' stone, Admiralty quarry (this may be considered quite equal in quality to 'whit-bed' stone); and 'whit-bed' stone, Inmosthay quarry (particularly adapted from its texture and uniformity for ornamental work).

III. 'Whit-bed' stone, Old Maggot quarry: *a* marked LI; and *b* marked IT and IE. The 'roach' stone, from War Department quarry, is an invaluable stone for external work in localities where any considerable strength and power of resisting mechanical wear are

required, as in connection with those portions of work which may become exposed to the continual abrasive action of water. The rough 'whit-bed' stone from Admiralty quarry, is also a highly valuable stone for work of a similar kind, where great strength is required, and particularly where the numerous irregularities in the 'roach' stone may be objectionable.

For *Internal* work, the following rank highest, on account of uniformity and comparative strength:—'base-bed' stone, Old Maggot quarry IT; 'whit-bed' stone, Independent quarry; 'base-bed' stone, Waycroft quarry; and 'base-bed' stone, New Maggot quarry. The following are inferior to those just named, both in texture and uniformity:—'Whit-bed' stone, Waycroft quarry; 'base-bed' stone, Old Maggot quarry, IE; and 'base-bed' stone, Inmosthay quarry. The 'base-bed' stone, from Old Maggot quarry, marked LI, and that from Independent quarry, are of low quality, as compared with the remainder; and no reliance can be placed on the durability of the 'roach' stone from Independent quarry, judging from the specimens received."

1666*i*. *Hopton Wood stone* is obtained from quarries situated near Middleton and Wirksworth, in Derbyshire, in the mountain limestone districts of that part of the country. An analysis of it gives:—lime 55·09, magnesia ·17, carbonic acid 44·30, water ·16, organic matter ·05, silicious matter insoluble in acids ·15, oxide of iron ·10, alumina a trace, and silica soluble in acids a minute trace = 100·02. It is well adapted for paving purposes, owing to the closeness and evenness of the grain; these properties give this stone its principal recommendation; its durability does not depend, apparently, upon any necessity for placing it on its quarry bed. The late Mr. C. H. Smith has stated in the *Builder*, 1864, p. 912, that "these extensive quarries have been worked from time immemorial; the material is decidedly *marble*, for it is fine grained, compact in texture, and quite hard enough to take a brilliant polish. The colour is a pale brownish white, certainly as white as Sicilian marble, which approaches to a bluish grey. It is much heavier than Portland stone, but lighter than Carrara marble. Blocks of very large dimensions may be obtained free from serious defects; and as it is an aqueous formation, hard, and well crystallized, there is no doubt of it standing weather extremely well. Both material and workmanship are less than those of Sicilian marble. In London, where it has not yet been used for building, a large quantity of it was laid down about the year 1854, for foot-pavements, close to the Parliament Houses in Old Palace-yard, and part of Abingdon Street; and, though in constant use, no symptoms of decay, or of the surface wearing away, are perceptible." It has been stated that the price of it would always oppose its introduction into the London market; and that the labour of the stone is about half as expensive again as that of Portland; but, probably, as the price at the quarries has lately been reduced, the first named disadvantage may be found no longer to exist. This stone is noticed for its many advantages, and as it is but little known to the profession.

1666*j*. We do not purpose to enter into a description of quarrying stone; but, besides the useful treatise by Burgoyne, published among Weale's Elementary Treatises, we would refer to the detailed mode of working at the Bath quarries, published in the *Builder* in 1862, p. 613.

French Building Stones.

1666*k*. Of the foreign building stones imported into the London market, it will suffice to name two of them:—the Caen, and the Aubigny, stones. The latter material is stated to be obtained from quarries situated at St. Pierre Canivet, a short distance from Falaise, in Normandy. It is probably of the same nature as Caen stone, namely, oolitic, but much more crystalline in its structure, with semi-transparent crystals, showing no appearance of ova; very fine grained; as hard or harder than Anston stone; nearly as heavy as granite; and able to support a greater crushing weight than Caen stone; when worked it requires to be sawn wet with sand. There are two workable beds, one averaging 24 inches, the other 15 inches, in thickness. G. R. Burnell, (in his remarks on the works at Bayeux cathedral, read at the Institute of British Architects, 1861, p. 257), stated that he was convinced the use of Aubigny stone in London would be attended with danger. M. Flachat chose this stone because it yielded more satisfactory results under the trials to which he exposed the various local stones, so far as their resistances to crushing weights were concerned; but his assistants expressly state in their published account of the works at Bayeux, that the Aubigny stone yielded easily under the action of frost, if used exteriorly. Any one who may have examined the mediæval buildings in Falaise must also be convinced that the Aubigny stone used there has decayed in a frightful manner. I am, however, disposed to believe that even when used in the exterior (query, interior) of a building, this stone is exposed 'to take on' a decay somewhat analogous to the mysterious decay which we know affects Purbeck or Petworth marbles in our own cathedrals. I fear that the edges of the various courses will ultimately crumble away like those of Purbeck marble. It may, however, be centuries before this effect is produced." Perhaps the only building erected with this stone in London, is that part of the old Schomberg House, Nos. 81 and 82, Pall Mall, which was rebuilt in 1851.

1666*l*. *Caen stone* is obtained from the great oolitic formation in Normandy, and has

been imported into England from a very early period; but it first appears to be named in documents after the year 1300. There was a cessation of its use after 1448, when Normandy was lost to this country; and it is not until the commencement of the present century that its employment here was resumed. This stone is now generally obtained from quarries situated at Allemagne, a small village on the right bank of the Orne at the gates of Caen, or from those of St. Germain de Blancherbe, commonly called La Maladrerie, the commune immediately adjoining that city, on the left bank.

1666*m*. The Caen stone of commerce is of a pale yellow colour and of a loose open grain, which when freshly quarried, soils the fingers like chalk, and is very friable. In many places it appears to have lost its oolitic character; and in others it is harder and more compact, being entirely formed of a species of lamellous spath, without any trace of oolites; the latter appearance is, however, principally to be observed in the beds which are worked between Caen and Falaise; at Allemagne and La Maladrerie the former prevails. Neither of these two latter quarries appear to have been opened for any great length of time, the stone used in the old city having been chiefly got on its site; and it is remarkable that the portions of the public buildings which required stones of larger dimensions than could be obtained from the upper beds of the oolitic formation immediately around the town, were executed in the Creuilly, Ranville, or Fontaine Henri stones, never in the stone obtained from the beds now worked exclusively for both the French and the English markets, and which beds have been rendered available with the advance of mechanical science. The upper beds, called the *bancs de bittes*, which yielded the stone in olden times, is generally speaking of a harder character, of a finer grain, and presenting a more crystalline appearance than that obtained from the lower beds; but even in these upper beds care is required in the selection, for the texture is far from uniform; while the small size of the stones is too often considered an objection to it, as the eight layers, between each of which occurs a bed of flint 2 inches in thickness, are of variable depth (between 11 inches and 26 inches), being about 18 inches on the average.

1666*n*. The lower beds comprise the *banc de chambranle*, 16 inches thick; the *banc de deux pieds un quart*, about 30 inches English thick, yielding a good stone, disfigured unfortunately by the fossils it contains; the *banc rouge*, 22 inches thick, of very bad quality and stained by ochreous iron ore, besides being traversed by numerous vertical vents; then the *gros banc*, 40 inches thick, a very good stone, but likewise disfigured by fossils; the *banc de fond*, usually from 18 inches to 30 inches thick, of a closer and finer grain than the last named; and then the *banc de* 81 *centimetres*, of very inferior quality, worked only for the immediate neighbourhood.

1666*o*. Experience proves that Caen stone will not resist the dissolving power of water charged with carbonic acid gas; and as the rain water of our large towns contains a considerable quantity of that gas, it is not expedient to employ this stone in any situation where water is likely to lodge or even to be taken up by capillary action, unless, indeed, the projecting parts be protected by metal. In upright walling above the plinths, and in the sheltered portions of cornices, it can be employed when judiciously selected; and in internal work, with safety and economy. The bedding of the stone should be observed. From the state of some buildings at Hâvre, it is considered that the sea air is particularly destructive to this stone; and it is generally believed that the stone from La Maladrerie is inferior to that from Allemagne. In Caen itself, the plinths or basements of houses are executed in granite, or in the Ranville, Cherence, or Creuilly, stones, which are practically non-absorbent; and, moreover, the Creuilly stone is used in the best buildings for the exposed portions of the elevation, although, of course, "Caen stone" is found at the very gates of the town.

1666*p*. More lengthened notices will be found in the accounts given in the *Builder*, vols. vi. and vii., entering into the qualities of the stone, from personal surveys of the quarries. When freshly quarried, this stone can be cut with the toothed saw, and carved with ordinary chisels, even more easily than Bath stone.

1666*q*. Table of the Weights of some French Stones.

Bed or Quarry.	Weight per cubic foot, avoirdupois.		
	lbs.	oz.	dr.
Caen, Franc banc bed	116	2	0
„ Banc de quatre pieds	118	0	8
„ Gros Banc	122	0	8
„ Pierre franche	123	3	0
„ Piere de trente pouces	128	5	0
Ranville, near Caen	142	6	0
Aubigny, near Falaise	150	6	8

1666*r*. The new façade of Buckingham Palace, erected in 1846–7, is perhaps the most remarkable failure of Caen stone. Mr. H. T. Hope's house, in Piccadilly, built 1849–50 has been considered one of the best specimens of its employment in London, as it has stood well. The projections were protected by lead or by slates. The crushing weight of Caen stone is about 2000 lbs. per inch superficial.

1666*s*. The *Kentish ragstone* is a limestone with a very small proportion of earthy matters, frequently subcrystalline, but ordinarily of a confused texture. When well chosen it is very hard and dense, and the labour upon it so expensive that it is very rarely used for anything but rubble masonry in districts remote from the quarries. The custom has been, therefore, to execute all the moulded or carved portions of the buildings in Caen or Bath stones, and even to carry up the quoins and jambs in those materials, whilst the intervening spaces, or the wall, are filled in with the rag. The colour varies from a lightish green to a deep blue, and although the colour of the two materials is at first very different, a few years' exposure causes them to harmonise in tint.

1666*t*. The district in which ragstone is quarried extends about thirty miles east and west through the central part of Kent, and averages from four to ten miles in breadth, comprising the towns of Sevenoaks, Maidstone, Lenham, &c. Reigate or firestone, and Tunbridge sandstone, are also afforded by the same formation, greensand. The ragstone is found in beds varying from six inches to three feet in thickness, alternated with fine sand known as *Hassock*, which in some beds becomes so consolidated as to form an occasional useful auxiliary to the ragstone, in buildings. The quality of the rag differs very greatly, according to the place in which it is quarried; some quarries only yielding stone of a hard flinty nature, almost unfit for building, while the stone obtained from others is almost as free working as Portland stone. The finest qualities are at present obtained from quarries situated at Boughton, near Maidstone, where they have been worked for several centuries. A section of them is given by J. Whichcord, in his pamphlet on the subject, published in 1846; wherein also are given the local names of the various beds. The Minera quarries, near Wrexham, supply a good firestone.

1666*u*. *Flint work*. This material, as used for a description of rubble work, was formerly much employed in the counties of Cambridge, Norfolk, Suffolk, Sussex, and Kent, where the chalk formation abounds, and is still used for the purpose in such localities. Flint is the name accorded to the nearly pure silicious earth, which by the action of fire becomes opaque and white, and is harder than quartz, which it scratches. The colour is usually grey, of various shades; but is sometimes black, brown, red, and even yellow. Flint is fragile, with a perfect and large conchoidal fracture, and being rarely laminated, it is broken with equal facility in almost every direction; the fragments are sharp. In the chalk formation it occurs in regular beds, consisting either of nodules or of flat tabular masses. At Brandon, in Suffolk, one of the places where flint forms an article of commerce, it is obtained from pits sunk in the chalk, which is within 6 feet of the surface. The first stratum is found in the clay overlying the chalk; when this has been removed, a shaft is sunk 6 feet in depth; if no flint is there found, a tunnel is driven for three feet horizontally, and another shaft is sunk; and so on alternately with tunnel and shaft till a depth of 40 feet is reached. The flint is found in *floors* about 8 feet below each other, and is obtained by tunnels being driven sometimes a furlong in length under each floor, and the flint broken down by crowbars. The small tunnels in the shaft form tables, upon which men stand and hand up the flint to each other from below to the surface; no machinery or tackling is used.

1666*w*. Flint is split upon the workman's knee, by sharp blows from a hammer with an oblate face, and squared upon a steel stake let into a wood block, with a blunt axe formed by passing a handle through an old flat file about a foot long, the cutting edge being $1\frac{3}{4}$ inches wide by $\frac{1}{12}$ of an inch thick.

Decay of Stone.

1667. In the paragraphs 1640 to 1648 have already been quoted some of the causes of decay and decomposition in stones, as stated in the Report of the Commissioners, and after the lapse of nearly thirty years since its publication, but few additional facts have been obtained on the subject. One of the most commendable essays relating to it is that by G. R. Burnell, read at the Society of Arts, in March 1860, which is likewise useful for the discussion thereon by some of the members learned in chemistry. We quote a few of the paragraphs for further elucidating some points important to those who have good building under consideration.

1667*a*. "Atmospheric moisture, when absorbed into building stones, acts upon them quite as much through the changes in its own volume. When the stone is placed in such a manner as that water can accumulate in any perceptible quantities between its various layers, and the position of those layers be such that the expansion of the water in freezing cannot take place freely, the respective layers containing the water will be violently de-

tached from one another. This is a more important consideration in the case of the *bedding* of stones, and it is unfortunate that the system of competition throws so great a temptation in the way of the practical builder as to render it a mere matter of chance whether this constructive law be observed or not, unless a costly system of supervision be organised, and thus the precautions often taken by the stone merchant to indicate the upper bed of the material he delivers, are defeated.

1667*b*. The chemical reactions which take place in building stones are mainly those arising from the oxygenation, or the hydration of the various ingredients of which those stones are composed. These reactions are independent of those resulting, in the interior of the country, from the agents directly presented by atmospheric moisture in the form of carbonic acid gas, sulphur, and ammonia; or upon the sea-shore, in the form of hydrochloric acid, or of common salt itself, in minute particles. Thus, if the oxide of iron be present in any notable proportions, it is likely to undergo changes of a nature to disturb the stability of the compound, and even the crystalline sulphates of lime are exposed to chemical decomposition, in consequence of the liberation of the sulphuric acid gas they contain. The other mineral salts, such as the silicates and the sulphates of iron, so often met with in building stones, are at times susceptible of very injurious decomposition; and the soda, potassa, or the organic matters the stones may contain, frequently give rise to the formation of new salts; mainly under the action of atmospheric moisture, it is true, but also under the influence of the partial decompositions which take place around them. It is to be observed, however, that the danger to building stones from this peculiar class of influences, is very small and very slow in its action, compared with the dangers arising from the mechanical disintegration produced by atmospheric causes: and that, with the exceptions of the actions of free carbonic acid upon the felspar of granites, the changes of state produced in limestones by the same agent, and the modifications of the abundant salts of iron in some peculiar stones, there is little practical necessity for dwelling upon this interesting but obscure branch of applied chemistry.

1667*c*. The actions capable of affecting the stability of the composition of ordinary building stones, by reason of the new forms of matter they superinduce, may principally be considered to be those resulting from the absorption of the gases of the atmosphere, and especially the process known by the name of *saltpetring*, or more correctly, of nitrification. This process displays itself in the formation of minute crystals, effloresceng from the interior to the exterior of the stone, and it leads to the destruction of the exposed surfaces of the latter, through the gradual removal of the minute particles, in consequence of the disintegration produced by the expansive action of the crystals in process of formation.

1667*d*. It is supposed that the organic matter diffused through nearly all stratified deposits gives rise to the formation of certain nitrates, such as the nitrate of lime and nitrate of soda, under the influences of damp, of air, and of light of certain descriptions —for nitrification certainly takes place most abundantly near damp ground, rising in a wall *pari passu* with the range of the capillary attractions of its materials, and upon the northern or shaded faces of the said walls. Not only does this nitrification throw off the minute and less adherent particles of the building materials themselves, whether they be of *stone* or *brick*, but it is also able to detach any protecting coat which may be put upon them, if the adhesion of that coat to the subjacent material should not be of a very energetic nature. Let the adhesion, however, be ever so energetic, if once the action of nitrification should have been established, it must run its course, and the amount of evil it is capable of producing will simply depend upon the quantity of organic matter originally contained in the materials, or susceptible of being absorbed by them from the atmosphere.

1667*e*. The secondary limestones which have not been affected by plutonic action, the loamy clays, some kinds of pit sand, sea sand, and some descriptions of natural cements, are particularly exposed to the danger of nitrification in damp situations, rendering it in vain to expect to be able to preserve any mural paintings, or even any sculpture of a delicate character.

1667*f*. Practically, then, the great agent of destruction of building stones, in any of its modes of exhibition, is the damp, or the water supplied by the atmosphere, directly or indirectly; the efforts of those who seek to prevent this destruction must be directed to combating this primary source of evil. Fortunately the precautions to be observed for this purpose are very simple, and they only require a little common sense on the part of the builders charged with their application, to the materials at least, which have been long before the public. The first and foremost rule is never to employ a porous absorbent stone in the ground, or in elevation; unless, in the former case, it be maintained constantly wet; or, in the second case, the absorption of moisture from the ground be prevented by the interposition of some impermeable material. Porous stones should not be used for the copings, parapets, window-sills, weather-beds of cornices, plinths, strings, or other parts of a building where water may lodge. Care must also be taken to bed such stones with mortars which are not exposed to develope in themselves, or are not likely to excite

in the stones, the efflorescence of any of the nitrates of soda, potassa, or of lime. If porous stones be used, it will be found that decay will commence, and be most apparent in the zone of alternate dryness and humidity, or as the workmen say, "between wind and water." The stonework about that part should therefore be executed in such a manner as to allow of its being easily replaced, if necessary; and in case the decay exhibits towards the interior, (as it will do when the exterior surface is covered with a coating impervious to the air), care must be taken to isolate the decorative plastering or wall linings from the surfaces which are likely to be covered by efflorescence.

1667*g*. A committee appointed by the First Commissioner of Public Works and Buildings, on the 23rd March 1861, "to enquire into the decay of the stone of the New Palace of Westminster and into the best means of preserving the stone from further injury," reported on—I. The extent and position of the decay. II. The causes to which it is attributable, taking into consideration the composition of the stone, and the influence exerted upon it by moisture, and by the acids diffused in the London atmosphere. III. The best means of preserving the stone from further injury. IV. The qualities of the stones to be recommended for future use in public buildings to be erected in London." This report was ordered to be printed 1st August 1861. It is also given in Adcock's *Engineers' Pocket-book* for 1862, p. 205–211.

Preservation of Stone.

1667*h*. Even when all the best precautions, as above detailed, have been taken, it is occasionally found necessary to protect the exposed surfaces of the soft and absorbent, or hygrometric, stones, with some coating which shall prevent their absorbing the injurious atmosphere. This is done in various ways.

1667*i*. I. *By painting*:—The objection to this process consists in the fact that, as the oil evaporates, the stone becomes again exposed, and even the absorbent powers of the stone itself contribute to this action; thus this costly palliative has to be often repeated, to the destruction of any delicate moulded work.

1667*j*. II. *By the injection of oleaginous, fatty, or waxy matters*:—These, it must be evident, can only act mechanically by closing the pores of the stone, and therefore, unless the surfaces be protected from the extremes of heat and cold, the heterogeneous materials thus affected must be acted upon in very different manners. Experience has confirmed this theoretical inference, and it has been found in practice that the protecting coats of any of the materials alluded to are gradually detached from the stone, and that they require to be renewed quite as frequently as does oil painting itself.

1667*k*. III. *By washing the face with a solution able to convert the material into an insoluble non-absorbent substance*:—This is the process introduced by M. Kühlmann, in which the carbonates of lime are washed with a solution of an alkaline silicate, as silicate of soda, or potassa, or "water glass" as he called it, with a view to converting them into silicates of lime through the elective affinities of the lime and the silica. In some cases this system has succeeded, and very great hardness, very great resisting powers, have been communicated to the stones operated upon. But unfortunately, the action of the silicic acid is a very slow one, and when the surfaces washed in the manner described are exposed to rain, it is by no means rare to find the solution carried away. Another objection is, that when the alkaline silicate acts upon the stone, the soda and potassa generally used are left free, and in effloresing they are likely to carry away the finer details of the sculpture; at the same time as they form to some extent deliquescent salts upon the face of the stone, they attract to it a dangerous amount of humidity. This process is only applicable to the preservation of the stones in which the carbonates of lime predominate.

1667*l*. IV. *By filling in the pores of the stone with an insoluble material which should effectually exclude water*:—This may be said to have been effected by the process patented by Mr. Ransome. The stone is first cleaned carefully from dust or other extraneous matters; then it is made to absorb as large a quantity as possible of the silicate of soda or potassa. When this solution has dried into the stone, a second wash is applied, consisting of the chloride of calcium or of baryta. The silicate of soda and the chloride of calcium are most frequently employed; and the effect of the respective applications is, that a double decomposition takes place in the washes, giving rise to the precipitation of a finely crystallised silicate of lime or of baryta in the pores of the stone, and an efflorescence of extremely soluble salts of the chlorides of soda or of potassa. The former remain in the pores, the latter are speedily washed away by rain. As the rate of contraction and expansion of the silicate of lime is, as nearly as may be, the same as that of the stone it is intended to protect, there is no danger of the precipitate being detached by this cause. This process, in contradistinction to that of Kühlmann's, is applicable to limestones, sandstones, bricks, plasters, and cements. It has even been suggested that it may be advantageously applied to chalk.

1667*m*. It must not be forgotten, however, that it is as important to prevent a stone from decaying, as it is to afford a protection to it when that effect has commenced. If

any internal decay or any organic decomposition, so to speak, be once allowed to establish itself in a building stone, it will be imposible effectually to arrest its progress. Efflorescence, for instance, will continue, however effectually the exposed surface of the stone may be closed by a mechanical or a chemical deposit, and thus even some of the results of Mr. Ransome's process appear equivocal. The student should make himself master of the attempts lately made to discover an universal remedy for protecting the surfaces of various materials; the following list of their authors were detailed by Mr. W. Tite, M.P., at the Institute of British Architects, January 1861:—I. Bethell's patent, 1838, perhaps never applied to stone. II. Hutchinson's, 1847, which has been chiefly applied to the Calverley stone of Tunbridge. III. Daines's, 1854. IV. Szerelmey's, 1857. V. Newton's, 1841. And VI. Ransome's, 1856. We consider it needless to notice here the inventions in detail. It is difficult to pronounce on their respective merits, but Ransome's perhaps promises the best results; it is mentioned in a subsequent paragraph.

1667*n*. Sylvester, in 1846, suggested the following very useful and simple recipe for protecting stone or brickwork from the absorption of water; it has been repeatedly tried and answers well in exposed situations, but requires a fresh application about every three or four years. Mix ¾ lb. of mottled soap in a gallon of nearly boiling water, and apply it in a boiling state over the surface of the work, steadily and carefully, with a large flat brush, making no lather, and filling up the crusty surface of the work, either of brick or stone. This is to remain for twenty-four hours to become dry and hard. Then ½ lb. of alum is to be mixed with four gallons of water and left standing for about twenty-four hours, so that the alum may be completely dissolved; this solution is to be applied in the same manner. Mr. G. G. Scott has used for the internal work at Westminster Abbey a solution of shell-lac in spirits of wine, which squirted into the stone work, appears to answer perfectly in securing the face from further decay arising from damp only. He also found it of some effect in the open air where defended from rain, but it failed when exposed to its action.

Artificial Stone.

1667*o*. The term is sometimes made to comprise not only *Terra Cotta*, which is noticed in this work in the section Brick, but also the many *Concretes*, which are described in the section Lime, &c. Those mixtures or concreted masses, having more affinity to the original they profess to imitate, are here described.

1667*p*. *Austin's artificial stone* was invented about fifty years since, during which period it has been well tested. It is used chiefly in the manufacture of statues, garden ornaments, chimney shafts, and the like. This material is generally considered to be little else than ordinary cement, but it is plain there is much more ingenuity in the matter; at all events, it is evidently a concrete of sand and so on, cemented by lime; it is not burnt as is often supposed, and much of its value is no doubt due to the manipulation of the materials.

1667*q*. *Ransome's silicious stone* was patented in 1844. Calcined flints ground to a fine powder were mixed with common soda (sub-carbonate of soda) rendered caustic, and water, the mixture being boiled under steam pressure; he thus obtained the silicate of soda in a liquid form. To one part of this *water glass* he added ten parts of sand, a little pounded flint, and a little clay; mixed the whole to a putty; made castings of the desired form under compression; dried these, *burnt* them in a kiln to a bright red heat, and so made them into blocks of stone. The chemical question was this:—the alkali of the soluble silicate of soda combined with a portion of the natural silica or sand, and thus formed an insoluble silicate or glass, as a cement, wherewith the remainder of the sand became concreted together. A sandstone was produced, and technically one of a silicious type; but its connecting medium was not crystalline as in nature, but as an equivalent, professedly vitreous. This vitreous element, however, was always seen to be its blemish, and the manufacture is now discontinued for the following more recent invention by the same patentee.

1667*r*. During the experiments made for obtaining a liquid or liquids wherewith to wash the surface of stone after it has been worked, Ransome selected and applied the silicate of soda, and upon the saturated surface a solution of chloride of calcium. A double decomposition then follows, not slowly but instantly, and the silicate of soda and chloride of calcium, the one, an insoluble substance filling the pores of the stone, and the other, common salt to be washed out by the weather. Pieces of the putty out of which the previously described silicious stone was daily made, *i.e.* sand mixed up with silicate of soda, were dipped in chloride of calcium, out of which it came changed to a hard and solid stone. This rather unexpected result led to the formation of an entirely new species of artificial stone, in a manner which was related by Professor Kerr at a meeting of the Institute of British Architects in 1863, from whose account we have been quoting.

1667*s*. *Ransome's Concrete stone* is the name given to this new material, invented in 1861. The process of manufacture now followed is first to dissolve flints in caustic alkali at a temperature of 350° Fahr., leaving them in a boiler for twenty-four hours. The liquid then produced, consisting of silicate of soda, is drawn off, and is allowed to evaporate until it becomes a thick matter like treacle. It is next mixed with clean pit sand incor-

porated with five to ten per cent. of chalk in a pug mill, and in four to five minutes this mixture is formed into a stiff putty. It is then pressed into a mould and afterwards either saturated with, or immersed in, a solution of chloride of calcium, which being rapidly imbibed, the formation of an insoluble silicate of lime and a soluble chloride of sodium or common salt results. This latter (about three per cent.) has to be removed by washing, to effect which it is placed in a hot-water bath for many hours. The employment of this new material as stone in building is gaining ground; for cast ornaments and moulded work it has been longer used, and probably it may yet be brought to serve for the chisel of the carver.

1667*t*. The committee of the Institute experimented on this material in 1864. Four-inch cubes were made of equal parts of sand and coarse ballast, with a quarter part of clay; on the third day a cube crushed with a weight of 9·35 tons; on the tenth day with 15·25 tons. With six parts of sand to one of chalk, on the third day a cube crushed with 6 tons; at ten days old, 9·40 and 13·25 tons. Other samples, however, proved to be weaker, as at eight and thirty-six weeks old, they crushed with 8·4 and 8·4 tons respectively, yet one of twenty-eight weeks crushed with 14 tons, apparently depending on the depth of the induration which in the weaker samples was only from 1 to 3 inches. A block formed of five parts of sand to one of fine silex bore 30 tons when three weeks old, without showing the least effect; it had been previously tested up to 20 tons. It will be well to contrast another sample formed of "all road scrapings from the neighbourhood of Ipswich" which at only *three days* old crushed with 28 tons; this was probably due to the silex contained in it. As another proof that its strength is entirely due to the complete induration of the material, a nine-inch brick made of four parts of sand, four of fine sand, and one of chalk, cracked when thirteen weeks old with 14 tons and crushed with 35 tons; this specimen was gradually filled with chloride of calcium being *poured* over it, and took fifteen minutes to saturate. Another at eight weeks with 4·2 and 30·0 tons; another with 20·15 and 38·8 tons; while a fourth cracked at 6 tons and crushed with 6·65 tons; these were *soaked* in the chloride of calcium, The tensile strength at twenty-eight weeks old varied as 47, 74 and 67 lbs. per square inch; while two specimens made of road scrapings, only three days old, broke with 101 and 97 lbs. per square inch, a strength also, no doubt, due to the silex contained in it.

1667*u*. A gallon of each solution is sufficient to produce a cubic foot of stone of the finer quality; but the cost of a block of coarser quality would be less than about half what the other would be. To render this concrete stone perfectly non-absorbent, the surface of the stone, after it is formed into blocks, is treated a second time with a wash of the silicate of soda, and a second application of the solution of chloride of calcium. These solutions are also applied for the preservation of other stones, or of brickwork; the silicate being diluted with water in proportions according to the absorbent character of the material, which must be clean and thoroughly dry before being operated upon. Tinting solutions are also supplied for harmonising with the natural colour of the stones. About four gallons of each solution will be, under ordinary circumstances, sufficient for each 100 yards superficial of surface.

1667*v*. Experiments conducted by G. R. Burnell, and reported upon by Professor Ansted in a paper read at the British Association at Cambridge, 1862, showed that the transverse strength of a beam 4 inches square resting one inch at each end, with 16 inches clear span, sustained a weight of 2,122 lbs. or 132 lbs. per inch superficial; whilst a similar bar of Portland stone broke with 759½ lbs., or nearly 42 lbs. per inch. The adhesive or tensile strength was proved by pieces of stone notched for the purpose, the sectional area at the weakest part being 5½ inches.

The patent concrete stone sustained - -	1980 lbs. = 360 lbs.	per inch.
Portland stone broke with - - -	1104 lbs. = 200 lbs.	,,
Bath stone ,, ,, - - -	796 lbs. = say 150 lbs.	,,
Caen stone ,, ,, - - -	768 lbs. = say 150 lbs.	,,

A 4-inch cube of the patent stone sustained a weight of 30 tons, nearly 2 tons per inch, before it was crushed.

1667*w*. The following result of chemical tests of this artificial stone, as compared with natural ones, will be found instructive. They were made by Mr. E. Frankland at St. Bartholomew's Hospital in December 1861. "The experiments were made in the following manner. The samples were cut as nearly as possible of the same size and shape, and were well brushed with a hard brush. Each sample was then thoroughly dried at 212°, weighed, partially immersed in water until saturated, and again weighed; the *porosity* or absorptive power of the stone was thus determined. It was then suspended for forty-eight hours in a very large volume of each of the following acid solutions, the alteration in weight after each immersion being separately estimated. The sample was then boiled with water until all acid was removed, and again weighed. Finally, it was dried at 212°, brushed with a hard brush, and the total degradation or loss since the first brushing was ascertained. The following numbers were obtained."

Name of Stone.	Porosity. Water absorbed by dry Stone. per cent.	Alteration in weight by immersion in dilute acid.						Loss by action of acid and boiling in water. per cent.	Further loss by brushing.	Total degradation from all causes.
		of 1 per cent.		of 2 per cent.		of 4 per cent.

"Whilst Portland, Whitby, Hare Hill, and Park Spring stones, are thus pointed out as the natural stones best adapted to withstand the influences of town atmospheres, they also indicate that Ransome's patent concrete stone will be found equal to the best of these, and there is nothing in the composition which would lead one to anticipate that it would suffer from exposure to the saline influences of the atmosphere upon the sea coast."

1667*x*. Bousfield's patent, 1856, consists of 80 or 85 parts of chalk and 15 or 20 of slaked lime, mixed together, moulded under pressure, and dried in the open air, when the blocks, says the patentee, "will be found to possess a degree of compactness and firmness resembling stone, which increases indefinitely with age, and if the ingredients are pure, will rival marble in whiteness and beauty." Barff's patent for an artificial stone was obtained in 1861. He takes 1 part of an aqueous aluminate of potash, with 3 parts of an alkaline silicate, or water glass (silicate of potash, however, not of soda), which will in a few hours set into a sort of dull glass, an artificial felspar in fact, perfectly brittle and of no very great tenacity, but altogether insoluble in water. With this silicate of alumina while in a liquid state, he makes up sand or any dust (as pounded stone) into a paste, moulding it into blocks, and drying them in the open air, until they have set hard. Silicate of soda and potash are extremely viscid, and anything mixed up or coated by them is rendered thereby impermeable; to get another solution into such silicates, much less behind it, to effect their decomposition, is considered impossible, the only alternative, therefore, is to put on the two solutions as one. Decomposition then setting in, mere dryness is all that is necessary to produce the material; but if the silicate of potash and the aluminate of potash be mixed up in a liquid, they remain liquid for any period within reason, and they may be mixed up with any materials selected, or washed over their surface. When put into stone it hardens and produces an artificial stone, without heat or further process. A previous patent, dated 1860, describes that silicate of soda or silicate of potash may be combined with, or decomposed by, carbonate of lead, carbonate of zinc, or other suitable material insoluble in water, which will decompose or chemically unite with the said silicates; proportionate quantities of chalk, sand, or other similar substance may also be incorporated with the compound, and thus enable it to be obtained at less cost, in accordance with the nature or description of the work to which it is intended to be applied. A piece of stone manufactured with carbonate of lead, powdered pumice stone, and silicate of soda, in proportions stated in the specification, produces a very hard stone, without the application of any heat.

1667*y*. Fluo-Silicic acid and silicate of potash are also applied to the surfaces of stones.

Sect. II.

GRANITE

1668. Among the primitive rocks of the globe, whose period of creation is considered by geologists as antecedent to that of organic beings, is that of granite, whose use in architecture seems to bid defiance to time itself. The term granite appears to be a corruption of the Latin word *geranites*, used by Pliny to denote a particular species of stone. Tournefort, the naturalist, in the *Account of his Voyage to the Levant* in 1699, is the first of modern writers who uses the name. The word seems to have been applied by antiquaries to every granular stone susceptible of use in architecture or sculpture, in which vague sense it was used by mineralogists, until about fifty years since, when true granite was classed as a particular mountain rock. Its constituent parts are concretions of felspar, quartz, and mica, intimately joined together, but without any basis or ground. These parts are variable in quantity, so that sometimes one, sometimes the other, and frequently

two of them, predominate over the third. The felspar is, however, generally in excess, as mica is the least considerable ingredient of the rock. In some varieties the quartz is wanting, in others the mica; but where these peculiarities occur, the granites must be considered as varieties, not as distinct species.

1669. The constituent parts differ in their magnitude, alternating from large to small and very fine granular. The colour, moreover, is very variable, depending principally on the predominating ingredient—the felspar, the quartz, and the mica having usually a grey colour. The felspar is mostly white, inclining to grey and yellow, sometimes red, and even grey, seldom milk-white, and always translucent. The mica is usually grey, and sometimes nearly black. The felspar in granite has usually a vitreous lustre, and of perfectly foliated fracture; yet in some varieties it becomes quite earthy, with the loss of its hardness and lustre; in other words, it has passed into porcelain earth. The appearance in question is sometimes produced by the weathering of the felspar, and sometimes it appears to be in its original state. When pyrites are found in the veins which traverse granite, the vicinous felspar and mica are converted into a species of steatitical matter by the action of the sulphuric acid formed during the decomposition of the pyrites. In Cornwall, there is a considerable portion of its granite in which earthy felspar is found. When felspar occurs in abnormal quantities, the granite becomes porphyritic, as the Devonshire granite, and that of St. Honorine (Calvados): the name being derived from the colour, which is purple. Schorl takes the place of the mica in some parts of Devonshire; and even the quartz is sometimes wanting, as is often the case in the elvans or courses laden with mineral matters in that district. When hornblende occurs instead of mica, the granite becomes syenite, as at Malvern, and at Syene, in Egypt: and when present with mica in about equal quantities, the material is called Syenitic granite. When mica is present in such quantities as to cause the rock to assume a slaty cleavage, it is called gneiss.

1670. Granite is not decomposed by acids, and is only imperfectly and slowly calcinable in a great heat. Those species which contain much white felspar, and only a small portion of quartz, like the greater part of the granites of Cornwall and Devonshire, are liable to decomposition much sooner than many of the Scotch granites, in which the quartz is more abundant, and equally disseminated. In the selection of the Cornish and Devon granites, those are to be preferred which are raised in the largest blocks and are easiest worked, which, for common purposes, answer well enough, such as for paving-stones and the like; but harder granite must be sought for than Devonshire or Cornwall produces, where the construction is of importance; for the masses in these counties are mostly in a condition of rapid disintegration and decay, which seems chiefly attributable to their containing a large portion of potassa. The Naval Hospital at Plymouth is built of a granite whose parts appear to have been well selected. It was erected between the years 1756 and 1764, and, except in the columns of the colonnades, does not exhibit symptoms of decay. In these, on their more exposed sides, the disintegration of the felspar has commenced, and lichens have already attached their roots to some parts of the surfaces.

1670*a*. The cause of the *decomposition* of granite is a point yet unsolved by chemists. Some state that the felspar, being acted upon by the carbonic acid in rain water, becomes decomposed, and is then easily removed, leaving the mica and the quartz in relief without any cementing material; and that the decay of the felspar does not take place by any known rules, for the more crystalline it may be, the more perfectly does it resist the decomposing action of atmospheric agents. Other scientific men are of opinion that the felspars containing soda generally decompose, whereas those which contain potash do not decay. It has also been considered that the kaolin or China clay was produced by the decomposition of the felspar with the granite; but it has been stated that so far as human observation could go, China clay never was true granite, and that atmospheric decomposition acting upon felspar, had never gone to the depth of 300 feet, at which depth finer China clay was found than nearer the surface: miles of country could be shown strewed with felspar; the quartz was gone, but the felspar remained. We must leave the decision in far more able hands.

1671. Red granite, sometimes yellowish, and generally interspersed with black mica, is found in Devonshire; at Mount Edgcombe there are tables of it equal to the finest oriental granite, and it is found also in other parts of England. For hardness, and in works where durability is indispensable, the granites from Mount Sorrel, in Leicestershire; Aberdeen and Dundee, in Scotland; and the Cheesewring of Cornwall, are to be preferred by the architect. These take an admirable polish, and are superior to all others which this island produces. The increasing demand of late years for this material, has caused many new quarries to be opened up in various localities. The red is generally harder than the grey sorts, and more difficult to work. The Peterhead, from the vicinity of Aberdeen, is perhaps the best, and it is, moreover, in appearance the most beautiful which Scotland affords; indeed, in point of beauty, it is only surpassed by the oriental granites.

1671*a*. Dartmoor granite is, in general, coarse grained, varying much in colour. The grey

sort is chiefly quarried and worked at Hay Tor on the east side, shipped at Teignmouth; and at King Tor and Rigmoor Down, on the west side, shipped at Plymouth. The Brown Willy district, worked at the Cheesewring quarries, near Liskeard; the granite is of a light grey colour, and was used in the piers of the new Westminster bridge. The granite of the eastern portion of the Hensbarrow district, near St. Austell, worked above Par, is of good quality; it is shipped from that port, and known as Lostwithiel granite: the western portion is remarkable for its liability to decomposition, and is worked for kaolin clay. The Carn Menelez district supplies the granite generally known as Cornish, shipped from Penryn and Port Navis: blocks of several hundred tons are often raised, varying from 20 to 70 feet in length, and of proportionate breadth and thickness. The finest grain is obtained in the Carnsew quarries, from whence were got the stone for the lodges and piers at the British Museum, the plinth to the Royal Exchange, the pedestal for the statue to Lord Clive at Shrewsbury, and that for the statue of Carlo Alberto at Turin. The columns at the entrance of the royal mausoleum at Frogmore are from Lamorna, south of Penzance; which, with Boswarvah and New Mill, to the west, have, with those at Penryn, supplied granite to most public works. Fremator granite, largely used at the steam dock yard at Keyham, is white in colour, and being very close grained, it can be brought to a highly finished surface, and is said to be very durable.

1671*b*. Hay Tor granite company supplies a granite of a very fine grain, hard, of unquestionable durability, and generally of a beautiful blue or grey colour; it can be obtained in blocks of any size that is capable of being removed with existing machinery. The quarries have supplied the Nelson column and its pedestals; the granite plinth and steps of the Royal Exchange; the statue and pedestal of King William IV.; part of the river wall of the Houses of Parliament; the plinth of the Sun Fire Office, &c.; the large landings and steps of the terraces at the Crystal Palace; the graving docks at all HM. Dockyards, as well as the ashlar steps and landings for the royal mausoleum at Frogmore. Grey granite from Lundy island, off the coast of Devonshire, is supplied for the first section of the Thames embankment.

1671*c*. The Port Nant granite, in Carnarvon bay, near Port Dinllaen, has been used at Liverpool for paving, for some years; for the tramway on Westminster bridge; for the Metropolitan drainage outfalls, and for the foundation works and pavement of the Thames embankment.

1671*d*. Granite is supplied from a comparatively limited extent in the north-eastern part of Aberdeenshire. The first or central portion is somewhat circular in form, having a diameter of about six miles, within which the rocks are of red granite of different varieties, typified by the fine warm coloured Stirling Hill stones; and secondly, of an annular space surrounding this nucleus, in which the grey and blue granites abound. Of these, the Cairngall is close-grained, hard and dense, and as obdurate as any of the red granites. At Pitsligo is obtained a light coloured bluish-white stone, which when fresh from the quarry, is wrought with greater facility than even some of the Scottish sandstones. It stands the weather well; but the want of railway communication prevents its being used at any distance from its own locality.

1671*e*. Rubislaw quarry was the first known quarry in Aberdeenshire, about two hundred and fifty years since, and furnished stones for paving London, and later for works at Portsmouth Docks and the Bell Rock Lighthouse. Since its introduction about 1820, various quarries have supplied granite for works at Waterloo Bridge (the balustrading), Sheerness Docks, upper side of London Bridge, &c. About 1822 Mr. A. Macdonald, of Aberdeen, reduced to practice the difficult problem of giving any required form to so stubborn a material, and communicating to its surface an enduring polish, which it is said, is retained under all atmospheric changes; nor does the material contract any stain with vegetation. The red granite quarries of Stirling Hill, near Peterhead, about thirty miles from Aberdeen, supplied the shaft of the Duke of York's column; the pillars in Fishmongers' Hall; the columns in the king's library in the British Museum about 1830; the pedestals for the statues in the same building; the columns at St. George's Hall, Liverpool, 25 feet in length in one block; and is now used in numerous buildings in nearly all the cities in Great Britain.

1671*f*. Grey or blue granite is supplied from the quarry of Rubislaw, but principally from Cairngall, which is more of a syenite than a granite, a clear blue finely-grained material, used for the finest work. This has been employed for portrait statues, as at Aberdeen, at Portsmouth, &c.; for the sarcophagus for the Duchess of Kent, and for that of the Prince Consort, both at Frogmore.

1671*g*. Argyleshire has only within the last twenty years been opened up for granite. Furnace quarry, near Inverary, is more of a Syenitic or porphyritic character than that of true granite, and is remarkably hard, in fact harder than that of Aberdeen. It is used chiefly for paving the streets of Glasgow. Bonaw Island quarry, near Oban, gives an excellent large-grained grey granite; it has been used in the harbour works, the flight of steps at the West End Park, &c., all at Glasgow, being obtainable in large blocks. Bonaw

Causeway quarry, near the above, though fine grained, does not supply large blocks; it is used for paving stones. Ardsheal quarry, north-east of Oban, has a good grey granite for general purposes. It is easily quarried in layers of any required length or breadth, and varies in thickness from 6 inches up to 3 feet. It is said to be less noisy and more safe as a paving stone than the generality of granites employed for that purpose.

1671*h*. The Ross of Mull quarries, in the island of the same name, supply granite of two sorts, red and pink, the felspar being in the former of a brilliant red, and in the latter of a delicate pink, tint. In its physical character it resembles the Aberdeen granite. It is now sent in large quantities to the polishing works at Aberdeen, and, moreover, these quarries can supply larger blocks than can those of Peterhead. Both the red and pink varieties, after having been polished at Mr. Sim's works at Glasgow, were used in the Prince Consort's mausoleum at Frogmore; at the Skerryvore lighthouse; the Liverpool Docks; the Londonderry Docks; the Glasgow Water Works, &c.; and the pink granite in the foundations of the early work at the new Westminster Bridge: the Tormore or red granite being used for the curb to the footways.

1671*i*. The only quarries in the south-west of Scotland are Kirkmabreck quarry, near Creetoun, Wigtown Bay, which furnishes a silver-grey granite, used for the obelisk sent by Mr. Sim to the Exhibition of 1862; and used for many years in the Liverpool Docks. Blocks of any size are readily attainable. Dalbeattie quarry, near Dumfries, has a large-grained grey granite, taking a high polish; there is a difficulty in getting large blocks free from black marks, but it is largely worked for general purposes, kerbing, &c., and for ornamental purposes.

1671*j*. The granites of Ireland are in general a speckled grey, inclining to white, as those of Wicklow, Dublin, &c.; also greenish from hornblende, as Mourne, Newry, &c.; reddish, as Galway. The granite of the Wicklow range is used more extensively than that of any other district in the island. It varies considerably even within a limited distance. Near Kingstown it is very hard, the quartz predominating; this is only used for plain heavy work. For more ornamental purposes granite is brought from Ballyknocken, or Golden Hill, about twenty miles distant. It contains a larger proportion of felspar and less quartz than that of Kingstown, and is therefore more easily worked, and is of a lighter and more uniform and handsome colour, though less durable. Granite of the Carlow portion of the same range is similar. Granite of Down is generally of a darker colour, and more finely crystallized; it is quarried at several places, especially at Newry, from whence it is conveyed by water to several parts of the north of Ireland; it can be worked into fine mouldings, and is of a dark speckled colour. Galway granite is commonly of a reddish colour, containing large crystals of flesh-red felspar; occasionally it has a bluish tint. To the west of Clifden blocks of a moderate thickness, but of great length and width, can be obtained. Granite to the west of Mayo is similar, but the greater part of it in that county is of a dark bluish-grey colour, difficult to work and seldom used. In Donegal and Tyrone it is gneissose, and of the same character, and reddish. Cavan granite is similar to that of Down, and but little employed. In the counties of Kilkenny and Wexford it generally resembles that of the great Carlow range before noticed.

1671*k*. The Bagnalstown quarries, in Carlow, supply four different qualities of granite; I. For plain work, portions being soft, others hard; some fine-grained, and others coarse; and red, blue, grey, and brown in colour; all are obtained from the surface of the land. II. A fine grit, employed for ornamental work even in the Gothic style, is very durable, and of a very white colour. III. Not quite so fine, but much used for buildings and ornamental work, being very white in colour. It lies in horizontal beds of about 1 foot to 15 feet in thickness, and from 15 to 20 feet in length; some beds run 40 feet long. In the hall of the Oxford University Museum is a slab of it, about 10 feet long, 5 feet wide, and 7 inches thick. IV. A very hard granite used for street crossings in and near Cork, not slippery. All these granites are approved for terrace steps, from 6 to 15 feet in length; for floors in stores, porches and halls, as in damp weather it absorbs the moisture from the atmosphere.

1672. Granite used for *paving* purposes is imported for *curbs and trams*, from Guernsey, Jersey, Aberdeen, and Devonshire. For *pitching and macadam*, from Aberdeen; Mount Sorrel, Markfield, and Grooby, all in Leicestershire; Guernsey; and a small quantity from Wales. Mount Sorrel granite is red in colour, and was employed for the altar steps in St. Paul's Cathedral. Granite from the Furnace quarries, at Inverary, as before noticed, is much used in the streets at Glasgow. Markfield and Grooby granites are dark green. The granite from the island of Herm, near Guernsey, was used for the steps to the Duke of York's column, but the cost of working and difficulty of shipping it at the quarry, have led to much discontinuance of its use.

1672*a*. Aberdeen granite is most extensively employed for *curbs, trams, and pitching*; the latter in thin cubes about 9 inches in depth, 3 inches in thickness, and not exceeding 18 inches in length, fair dressed throughout, it being considered the best granite adapted for the traffic of London, as it is very durable and less slippery than most other granites,

such as that of Guernsey, for instance, which is therefore now seldom adopted. The Welsh granite has the same fault, for, with a large amount of traffic in dry weather, it becomes necessary to throw gravel over it. Guernsey macadam, broken to pass through a 2½ inch mesh at the largest, is found to be by far the best material for the purpose, one coat properly applied outlasting two of any other granite. The Devon granite being coarse in grain, is used only in curbs for second-rate streets, while for pitching it is not to be compared in price or quality with that of Aberdeen. Blue Bombay, and blue Port Philip granites, are hard and tough, and make good second-class roads; while grey China granite is soft and friable, and only good for the foundation of a new road.

1672*b*. We are indebted for several of the details here given on this subject, to the article in the *Dictionary of Architecture* of the Architectural Publication Society. The *Builder* for 1866 has also entered on the merits of Scottish granites.

SECT. III.

MARBLE.

1673. With the architect and sculptor the name of marble is applied to all stones, harder than gypsum, that are found in large masses, and are susceptible of a good polish. On this principle, under the head of marble, are included many varieties of limestone, porphyry, and even granite and fine-grained basalts. But with mineralogists the word is used in a much more restricted sense, and is confined to such varieties of dolomite, swinestone, and compact and granularly foliated limestone as are capable of receiving a good polish.

1674. The *external characters* are as follows: colours white, grey, red, yellow, and green. Has generally but one colour, though it is often spotted, dotted, striped, and veined. Occurs massive, and in angulo-granular distinct concretions. Internally it alternates from shining to glistening and glimmering; lustre intermediate between pearly and vitreous. Fracture foliated, but oftentimes inclining to splintery. Fragments indeterminate, angular, and rather blunt-edged. More or less translucent. Brittle, and easily frangible. Its *chemical characters* are, that it generally phosphoresces when pounded, or when thrown on glowing coals. It is infusible before the blow-pipe. Dissolves with effervescence in acids.

Constituent parts,		
Lime - - - -	56·50	
Carbonic acid - - -	43·00	
Water - - - -	0·50	
	100·00	

1675. All the varieties may be burnt into quicklime; but it is found that in many of them the concretions exfoliate and separate during the volatilization of their carbonic acid, so that by the time that they become perfectly caustic, their cohesion is destroyed, and they fall into a kind of sand, a circumstance which renders it improper to use such varieties in a common kiln.

1676. The varieties of marble are almost infinite, and their classification would be perhaps useless here. Those employed by the ancients, as well as porphyry, are noticed in the GLOSSARY. Parian marble consists almost entirely of carbonate of lime; that of Carrara, in Italy, is often mixed with granular quartz in considerable proportion. Dr. Clarke says that while ancient works in Parian marble remain perfect, those in Pentelic marble have become decomposed, and sometimes exhibit a surface as earthy and rude as that of common limestone. This is considered to be principally owing to veins of ex-

traneous substances which intersect the Pentelic quarries, and which appear more or less in all the works executed in this kind of stone. Parian marble has a waxy appearance when polished; it hardens by exposure to the air; and must be held in estimation even now, as the material from which were formed the Venus di Medici, the Diana Venatrix, the colossal Minerva Pallas of Velletri, and the Capitoline Juno. A green and a red marble are sent from Greece. The marbles known as Verde antico and Verde di Corsica are composed of limestone, calcareous spar, serpentine, and asbestos.

1677. The principal part of the supply to England of foreign marble is from Carrara, a small town or village of Tuscany, in Italy. The quarries at this place were celebrated from an early period, and spots are still shown about them whence they dug the marble for the Pantheon. Masses of marble are sometimes procured there nine feet in length and from four to six in breadth. The quarries are the property of the principal inhabitants of the town, who carry on an extensive trade in the article; but the difficulty of choosing the marble has induced artists to settle there for the execution of their works, and the consequence is, that sculpture abounds and flourishes in the town. The white or Statuary, Italian-veined, Dove-coloured, Pavonazzo or purple veined, and Ravaccione (called Sicilian, supposed to have obtained its name from early ship loads of it having been reshipped or sent on from some port in Sicily, at which the vessel touched in its voyage) marbles, are but very slight variations of the same substance; the Dove and "Sicilian" have a little more carbonaceous matter in their composition; but they are all procured from quarries in the immediate neighbourhood of Carrara. Serravezza in Lucca, produces Statuary, Ravaccione, veined or Bianco chiaro, Mischio di Serravezza, Bardiglio, and Bardiglio fiorito.

1677*a*. All varieties of Carrara marble have perishable qualities, which ought to preclude them from being ever applied to external purposes in this country. After exposure to the weather for thirty or forty years, disintegration through its entire mass, but mostly on or near the surface, evidently takes place; after the lapse of about a century, more or less, according to the quality of the marble, the entire substance falls into a kind of sparkling sand. The group of Queen Anne, &c., in front of St. Paul's Cathedral, sculptured by Francis Bird, in the beginning of the last century, has long since been painted, in order to preserve it a little longer from total ruin. Even the statue of King George III., by J. Wilton, placed under cover, at the old Royal Exchange, but exposed to the atmosphere, when taken down to be repaired about 1825, was found to be too much decomposed to be put up again; it has long since crumbled to dust. A mural monument by J. Nollekens, erected about 1780 over the centre door within the portico of Bloomsbury Church, fell on to the pavement during the winter of 1837–8, so thoroughly pulverized as to resemble a fall of snow rather than bits of marble. Milan Cathedral is built of the white marble of Monte Candoglio or Candido, on the Toce, a tributary of the Lago Maggiore, selected as better fitted to stand the atmosphere than Carrara marble, of which it is usually said to be built: the "7,000 statues" (1863) are most probably all of the latter material.

1677*b*. The Ravaccione, or so-called "Sicilian" marble, is expected to resist the action of an English atmosphere longer than Italian veined, or white Carrara marble. On examination, however, it will be found that its chemical and mineralogical character scarcely differs from them, except in weight, hardness, and as containing a little more carbonaceous matter. The Marble Arch, erected 1825–7 in front of Buckingham Palace, was removed to its present site 1850–1, when it was found necessary to rub the exposed surfaces with sand and stone, as they were in a state of disintegration. Perhaps the tomb by Sir F. Chantrey, executed about 1820 in the burial-ground of St. John's Wood Chapel, is the oldest specimen in London, if not in England. The surface may now be abraded with the fingers, like sand. This material has of late years been extensively used in the cemeteries round London. But on a careful inspection of stones of three years' date, it will be found that the polish is nearly gone; and even the paint of the lettering has entirely disappeared. Frequent changes of temperature also tend to destroy Carrara marble more rapidly than atmospheric influences; thus the mantel of a chimneypiece is invariably disintegrated long before any other part. These useful practical remarks have been mostly derived from a paper by the late C. H. Smith, given in the *Builder* of 1864, who in conclusion strongly urged the employment of Hopton Wood stone (par. 1666*i*.) in lieu of it, for all out-door works.

1678. There is a beautiful species of yellow marble obtained from the quarries near Siena, in Italy, and known in England as Siena marble; but the quantity now imported is not very great, and what is introduced is very poor in colour. A good quality, both in colour and vein, can, however, be procured at the quarries by special orders.

1678*a*. The marbles of Sicily, little, if at all, employed in this country, are enumerated as follows:—Marmo di Trapani, of a grey colour; M. di Castelnuovo, of a yellow colour; M. di Segesta, of a yellow colour; M. di Taormina, of a red colour; M. di Parco, of a yellow colour; M. d'Ogiiastro, of a red colour; and M. di Castelaccio, of a grey colour. The two last-named marbles are readily obtainable in blocks 12 or 13 feet

long. Specimens of some, if not all of these, are included in the fine collection of polished marbles made by the learned Corsi of Rome, an account of which he published: the collection was subsequently brought to England, and is believed to exist at Liverpool. Each specimen it contained is no less than 8 inches Italian long, 4 inches wide, and 2 inches thick, and highly polished on all sides.

1679. Many of the marbles of France and Belgium are extremely beautiful. They are chiefly used in this country for chimney pieces. The following is a list (including others) of those so worked, supplied from one of the Belgian workshops:—Rouge royal; Bleu Belge; Rouge Griotte; French red; Saint Anna; Noir Belge; Noir Belge, second quality; Breccia (Brêche); Breccia and black; Breccia Romana; Breccia rose; Saint Gerard; Sicilian; Sicilian, white veined; Pavonazzo; Statuary; Statuary, second quality; Malachite; Ver de Mer; Black and green; Porphyry; Brocatello; Siena; Siena, second quality; Italian Griotte; Black and gold; Black and gold, second quality; Bardilla; and Sarracolin. Another marble, named Saint Mont Claric, is a pure black.

1680. The marbles of Spain are likewise very fine, but are not exported. A specimen of the "Emperor's Red," of unusually fine quality, was presented to the Queen by the late Don Pedro, King of Portugal, for the royal mausoleum at Frogmore.

1681. The marbles of the British Islands deserve more notice from the English architect than they have hitherto received. In England there are but few as yet quarried of granular foliated limestone, the greater number of varieties of them belonging to the floetz or secondary limestone. The most remarkable, and perhaps most beautiful, of the English marbles, is that of Anglesea, called *Mona marble*, and much resembling Verd antique. Its colours are greenish black, leek green, and sometimes purple, irregularly blended with white, but they are not always seen together in the same piece. The white part is limestone, the green shades are said to be owing to serpentine and asbestus The Isle of Man marbles are—I. Black flagstone (Posidonia schist) from Poolvash the quarries of which have been worked for upwards of two hundred years; and furnished the steps in St. Paul's Cathedral, presented by Bishop Thomas Wilson. II. Grey marble (encrinital and shelly limestone) from Poolvash, used for tables and chimney ornaments. III. Black marble (lower carboniferous) limestone, from Port St. Mary, extremely hard and durable, taking a good polish; raised in blocks and flags of great size, and used for piers, floorings, and tombstones. IV. Pale marble (carboniferous limestone (from Scarlett. Castle Rushen, nine hundred years old, and other places, are built with this most durable material. V. Spanish Head flagstone (clay schist), Port St. Mary; is a durable material, and used for lintel and gate posts; it is slightly elastic when in thin flags, and can be raised in square slabs of 16 feet. VI. Peel freestone (old red sandstone), from Craig Millin; of this stone a large portion of Peel Cathedral was built in 1226. (Cumming, *Isle of Man, &c.*)

1681*a*. The ornamental marbles of Derbyshire are mostly confined to the 1st, 2nd, and 3rd classes of limestones, which are separated from each other by the *toadstone*, an amygdaloidal trap rock. These marbles are usually distinguished by their colour, as white, grey, dove, blue, black, and russet; or by physical peculiarities, depending mostly on their fossil contents, as bird's-eye, dog-tooth or muscle, entrochal, shelly, and breccia marbles. Quarries of *black marble* are situated near Ashford, where machinery for cutting and polishing these marbles was first used in 1748. The beds of black marble seldom exceed 7 or 8 inches; it is difficult to be obtained of any considerable surface free from "shakes," or small veins of white spar. It is also procured at Matlock and Monsaldah. A brown marble, in thin bands of various depths of colour, is called "rosewood," as it presents the appearance of it when polished. It is one of the hardest and most durable of the Derbyshire marbles. A red marble, resembling Rosso antico, is found chiefly near Newhaven, in lumps of no great size. These and other Derbyshire marbles are principally used for inlaying work, as vases, tables, &c., but chimney pieces, columns, &c., are now made at Ashford, Bakewell, Buckland Hollow, and at Derby. This Florentine work, as it is called, is remarkable for fineness of execution and beauty of design, and is almost confined to the county.

1681*b*. A beautiful greyish-black coralloid marble is also found in Derbyshire and in Wales. The corals it contains are of the porous kind, of the most elegant species, lodged at all angles and in all directions, and are in general about one inch and a half long and three quarters of an inch broad. The other species of coralloid marble is equally beautiful and compact, fine, even texture, very hard, of a deep jet black, and capable of a very high polish. It is variegated with species similar to the above, but smaller, and of a less elegant texture; among these it has usually a great number of sea shells, both turbinated and bivalve, the coral and shells being of a pure snow white.

1681*c*. The North Devonshire marbles are abundant and diversified. There are varieties of black and white, from Bridestow, South Tawton, and Drewsteignton. Some of the Chudley, Staverton, and Berry Pomeroy, marbles, have a black ground with large veins of calcareous spar traversing it in all directions. The variegated marbles are gene-

rally reddish, brownish, and greyish, variously veined with white and yellow, and the colours are often intimately blended. The South Devonshire marbles, now chiefly worked at St. Mary Church, Torquay, from the Babbacombe limestone, are called after the name of the estate or quarry from whence they are taken, such as the Petiton, Ogwell, Ashburton, Babbacombe, &c. The colours are red, grey, and variegated, of almost every tint. The sizes of the blocks vary from 1 to 10 tons; the ordinary length runs from 4 to 5 feet; 7 to 8 feet is considered as a good length. At Ipplepen are reddish varieties that are extremely handsome. They are of different qualities, as compact, porcellanic, granular, crystalline, shelly, magnesian, pozolanic or water, stinking or swine. The Bartons quarry at Ipplepen, belonging to Mr. Field, of Parliament Street, is worked at 80 to 100 feet in depth; the lowest beds are about 8 feet thick, and of a mottled character, being dark red and white in colour; the deposit over it is streaky and lighter in colour. Blocks of 18 feet square are now conveyed to London. This quarry has lately supplied the monolithic polished shafts for the forty columns (18 out of one block), each 12 feet 3 inches in length, and 18½ inches diameter on the fillet, with many others, for the new building of the National Provincial Bank of England, in Bishopsgate Street. The bases are of Irish black marble, and the caps of the cream-coloured Huddlestone stone. In the corridor of the new Freemasons' Hall are four columns, two being from the Bartons quarries, and two of Languedoc marble: eight others are placed in the coffee-room of the Charing Cross Hotel. The limestones of Plymouth are not so fine. They are of two sorts; one, an ash colour shaded with black veins; the other blackish grey and white, shaded in concentric spots interspersed with irregular red spots; or black with white veins about a quarter to an inch in width.

1681*d*. *Serpentine*, "beyond all question, the most beautiful of the ornamental stones of this country" (Hunt), is chiefly found in the sea-bound peninsula called the Lizard, the most southerly land in Great Britain. This rock, with another called diallage, constitute nearly half of the Lizard peninsula. Serpentine has evidently been under the influence of heat. At one spot it seems to shade off into the hornblende slate in which it is embedded; at another, it has every appearance of having been thrust up among the hornblende slate. Sir Henry de la Beche wrote, many years since, that serpentine *ought* to be employed for decorative purposes. He named Landewednack, Cadgwith, Kennack, Cove, and Goosehilly Downs, as four sites whence beautiful specimens might be obtained, varying in colour, as, an olive green base striped with greenish-blue steatite veins; another specimen, very hard, with a reddish base studded with crystals of the mineral called *diallage*, which when cut through and polished, gives forth a beautiful metallic green glitter, heightened still further by the reddish tint of the mass in which it is embedded. To the Exhibition of 1851, Penzance sent fine specimens in all kinds of ornaments. The blocks are small, but sometimes they have been obtained 7 feet in length and 4 or 5 tons in weight; the largest was 8 feet long, 3 feet wide, and 2½ feet thick; from 2 to 3 feet long is the usual size. The best blocks are worth from 5 to 10 guineas per ton, according to their weight, the larger the size the higher is the value in an increasing proportion. Chemically, steatite and serpentine differ little from each other, and as they are quarried in juxtaposition, specimens of both kinds are selected for use; but serpentine being much harder and more richly coloured, is appropriated to the larger articles.

1681*e*. In the *Builder* of 1865, p. 877, it is stated that serpentine is not a marble, but a tale containing a tolerable quantity of chromate of iron. It is sometimes good for external ornamentation, but never when it has the white streaks so commonly seen in it. Hunt's *Handbook to the* 1851 *Exhibition*, gives the following analysis of serpentine obtained at the Lizard:—Magnesia, 38·68; silica, 42·50; lime and alumina, 2·10; oxide of iron, 1·50; oxide of manganese, 1·0; oxide of chromium, 0·30; the colouring matter is probably a combination of chromium, iron, and manganese. In his *Handbook to the* 1862 *Exhibition*, it is called a hydrated silicitate of magnesia, composed of silica, 43·64; magnesia, 43·35; and water, 13·01 = 100. Besides the supply from the Lizard, it is obtained in Anglesea, Portsoy in Banffshire, Unst and Fetlar in Scotland. The "green marble," or serpentine, of Connemara, is noticed among the Irish marbles. This material is sawn by steam power with sand and water; and when brought into the form required, it is ground, turned, rubbed, and polished until it presents a beautiful glossy surface, said to be capable of resisting grease and acids, which is not the case with marble in general.

1681*f*. It is said that two brackets of old monuments in Westminster Abbey; the panel-bordering of the monument erected to the memory of Addison; the brackets of a chimney-piece at Hampton Court, are all carved in serpentine, and the present condition of these specimens shows the durability of it. "Equal to granite in durability," is the statement made in advertisements, but probably some further time must elapse before such a statement can be endorsed, though it may be allowed that it appears to stand atmospheric influences remarkably well. Experiments on the strength of serpentine have been noticed in par. 1502*g*. Therein is mentioned a shaft of Poltesco grey-green Devonshire serpentine, one of the weakest examples, which went across and not with the vein: the latter running

in the line of the diameter. The green serpentine has been used lately on the outside of some offices in Cornhill; and the red quality in 1853 in Leicester Square.

1681*g*. Purbeck, Petworth, or Sussex marble, is the name of a material common to Derbyshire, Dorsetshire, the Isle of Wight, Kent, Surrey, and Sussex. It is found at Dinton, near Aylesbury, and it occurs at Boulogne and at Beauvais, in France. In some places, as in the most westerly quarries near Corfe Castle, and at the top of the Isle of Portland, the Purbeck stone is so highly coloured and fine-grained, that it is chiefly identified as belonging to the fresh water deposits by the fossils it contains. In general, the stone may be said to be fine grained in the quarries north and west; while in those approaching the east the pattern is larger, the shells well defined, and scarcely any of them broken; the marble from this district is therefore handsomer, and more in request for ornamental purposes. Purbeck was well known for its quarries during the middle ages, when the marble was in great request for decorating the clustered shafts and sepulchral tombs, and for pavements, in churches. At the present time, there is scarcely sufficient demand to keep more than a few men at work, and this at Woody-hyde, near Corfe Castle, where the genuine material or Purbeck marble can be obtained, and that quarry is a *hole* more than a quarry. It has been stated that, during the middle ages, this material was also obtained from quarries at Parham Park, six miles north-east of Arundel, but there are now no traces of it left on the surface.

1681*h*. All varieties of Purbeck marble contain a large proportion of clay in their composition, which is one chief cause of their perishable nature. In the interior of buildings the moisture in the air will be condensed, and absorbed into the argillaceous portion of the marble. While this process is going on, the lustre of the polish is gradually diminished, the colour is altered, its hardness and cohesion destroyed, until the surface is completely changed to a dull earthy appearance, and decay results, which will be facilitated in proportion to the amount of clay contained in a given mass. When, as in small columns, this material is placed with the planes of lamination in a vertical position, there results another and a greater tendency to decay. The clustered columns in the Temple church, though renewed in 1840–42, had already lost much of their polish in 1853, a preliminary stage towards decay. The large ancient columns supporting the clere-story at Westminster Abbey, have now scarcely a trace left of their original surface. (C. H. Smith, *Transactions*, Institute of British Architects, 1853). As already stated, this sort of marble is obtained in Kent, where it is also known as Bethersden marble, and likewise as Lovelace marble, obtained near Ashford. In the east and west sides of the new quadrangle of St. John's College, Oxford, are sixteen entire columns of "Bletchingden marble," which were put up in 1631–35. It may be seen in Hythe Church and in some of the neighbouring churches, where it is often varnished in lieu of being polished. The Purbeck marble columns used in Lincoln Minster, in 1186–1200 are asserted to have been worked up by vinegar.

1682. Of the Scotch marbles the principal are the *Tiree*, of which there are two varieties, red and white. The *Iona*, whose colours are a greyish white and snow white, sometimes intermixed with steatite, giving it a green or yellow colour in spots and known under the name of Iona or Icolmkill pebbles. It does not take a high polish. The *Skye* marble, of greyish hue, with occasionally various veins. The *Assynt* varieties of white, of grey, and dove colour. *Glen Tilt* marble, white and grey, with occasionally yellow and green spots. Marble of *Balliculish*, of a grey or white colour, and capable of being produced in considerable blocks. *Boyne* marble, grey or white, and taking a good polish. *Blairgowrie*, in Perthshire, of a pure white colour, fit, it is said, to be employed in statuary and for architectural purposes; and *Glenavon*, a white marble, said by Williams (*Natural History of the Mineral Kingdom*) to be a valuable marble, is not used, from the remoteness of its situation and the difficulty of access to it.

1683. Ireland is rich in marbles. The dark colours vary from jet black to dark dove colour, purple, blue, and grey; the light colours, from the pure snow white to the celined, cream coloured, pink, and light grey. The variegated consist of the serpentine, black and white veined, mottled, and those marked with fossil organic remains. The black marbles, which are those of most value in Ireland, are extensively met with, and belong to the lower limestone. The merchantable beds of the best quality, which have been extensively worked, are met with in the counties of Galway, Limerick, Carlow, and Kilkenny. It is also found in the counties of Mayo and Waterford. The best quarries are considered to be those close to the town of Galway, near the bank of Lough Corrib. It occurs in three beds, varying from about 9 to 12 inches in thickness. One is called the "London bed," as it supplies most of the black marble exported to London. Blocks are raised of an average size of about 5 to 10 feet in length, and 4 to 5 feet in width; others 20 feet in length can be obtained. Some blocks 16 feet in length were sent over for a staircase for the Duke of Hamilton's seat in Scotland, who was also furnished with landings and solid balustrades worked to a fine polish. Angliham and Merlin Park quarries supply black marble of the very finest description, receiving a high polish. Steps of it were supplied for the porticos at St. Paul's, the staircases at Marlborough House, Hampton Court, and Kensington Palace, under Sir C. Wren, cir. 1700. At Oughterard, the beds contain more

or less silica, rendering them not so valuable. At Kilkenny, it abounds with shells, which become more conspicuous as the marble dries Kilkenny marble was once extensively employed in Ireland, but the black is now preferred. The polish of black marble, while it is considerably affected by dampness, is much improved and preserved by being kept dry.

1683*a*. Dark grey and dark mottled grey marbles are met with chiefly in King's county and in several parts of the county of Cork. Near Tullamore, marble is obtained in large blocks capable of receiving a fine polish, and is much used for chimney-pieces and ornamental works. The limestone around Cork produces easy working marble of a light grey or dove colour, and more or less mottled, receiving a good polish. In the primary districts of Donegal, a light grey and bluish grey coloured marble of close grain is found to a great extent; most of it, however, is hard to work from the quantity of silex it contains. The same kind of a bluish tint is very frequent in Connemara. It is compact in texture, but does not always produce a satisfactory polish. *White marble* occurs in the western portion of county Donegal, differing much from that of Connemara. It is of comparatively easy conversion, and can be obtained in cubical blocks in great quantities; its very coarsely granular texture, however, is prejudicial to it for many purposes; for boldly executed works in sculpture, where the expense of carriage would be avoided, it might be advantageously employed for many purposes; but it will not vie with the marble of Carrara. The Connemara white marble is hard and fine, and the strongest yet found; it cannot, however, be procured in large blocks free from streaks, which pass through the blocks parallel with the beds. At Chevy, near Dungannon, county Tyrone, a very delicate cream coloured marble is obtained, very compact in texture, receiving a high degree of polish, and blocks of great length can be procured. The coarsely crystalline and fossiliferous limestone at Ardbraccan produces light coloured marble of easy conversion.

1683*b*. Of the variegated marbles, the *Siena* of the best quality is perhaps the most beautiful. It is obtained in several places in King's county; but the best, the veined or mottled Siena, is found near the Seven Churches. It is susceptible of a high polish, and exhibits many bright and distinct colours. Marble of the same character also prevails, having a dove coloured ground, varied or mottled with Siena colour. In the county of Armagh, a Siena, or rather a brownish red marble, is found, containing a great number of fossil shells; several varieties of colour, from a very light reddish brown to a rather dark red, are also met with, more or less marked with shells. At Pallaskenry in the county of Limerick, a dark red and mottled marble is abundant, and has been much used. A red coloured marble, of a compact but slaty texture, occurs in the county of Cork, extending from the city in a narrow seam, for a distance of several miles. It is hard to work and dull in colour: at one time it was extensively used.

1683*c*. The serpentine, or *green marble*, as it is usually called, of Connemara, in county Galway, is of a dull green colour. Blocks are raised of considerable size, from which slabs can be obtained, at Barnanoraun quarry, near that at Recess; and at Letternaphy quarry, near Cliden; the latter being rather coarse in quality; while at Tievebaun quarry, near Recess, the marble is dark green, very sound, and free from shakes of any kind. Black and white marble, and that of a mottled character, occur near Cork, in the counties of Waterford, Longford, and Kerry; some of the varieties are very fine; that obtained near Mitchelstown is well marked and receives a high polish. The limestone obtained near the Seven Churches in King's county, when polished, produces a good marble of an even grey colour. It is strongly mottled with very numerous fossil organic remains. It is easily worked, and raised from the quarries in thin beds. This marble, in a polished state, has been used in the construction of one of the principal ruins at the Seven Churches; some of the stones retain their polish to this time, while others exhibit decay. (Wilkinson, *Geology, &c. of Ireland*, 1845). A fine purple marble is found at Loughlougher in county Tipperary, which is said to be beautiful when polished. Some of a purple colour, and purple and white intermixed with yellow spots, were to be procured in the islands near Dunkerron in the river Kenmare.

1683*d*. TABLE OF THE WEIGHTS OF MARBLES.

Name.	County or Country.	Weight per cubic foot, avoirdupois.
		lbs. oz. dr.
Black	Kilkenny	171 6 0
Tiree	Hebrides, Scotland	172 5 0
Carrara, Statuary	Tuscany	168 10 5
„ Ravaccione	„	169 2 8
Ipplepen, Bartons quarry	Devonshire	163 6 0

Its tenacity is stated at 6,000 lbs. per square inch, and its crushing weight is also put at 6,000 lbs. per square inch. (Hunt.)

Sect. IV.

TIMBER.

1684. The information we propose here to lay before the reader relative to the different species of timber is extracted from Miller's *Gardener's Dictionary*, Rondelet's *Art de Bâtir*, *Rees's Cyclopædia*, and Hunter's edition of Evelyn's *Sylva*. To give any thing like the information that would satisfy the botanist would be out of place in an architectural work; and we therefore confine our observations to those which will be useful to the student.

1685. Oak. Of this most valuable timber for building purposes Vitruvius (lib. ii. cap. ix.) enumerates five species, which it would now be difficult to identify. That some species of the Quercus of the botanists are more valuable for building purposes than others no doubts exist. Evelyn seems to commend especially the Irish oak, because of its withstanding the efforts of the worm; but it is not easy to ascertain the particular species to which he alludes. In the present day the Sussex oak is esteemed the most valuable; a value, according to some authors, derived from the nature of the soil and from good management in the culture, which is an object of no small importance.

1686. Generally, it has been usual to consider England as producing, without difference in quality, but one species of oak; but two sorts are well known to the English botanist, the *Quercus Robur* and the *Quercus Sessiliflora*. The former is found throughout the temperate parts of Europe, and is that most common in the southern parts of England. Its leaves are formed with irregular sinuosities, and their footstalks are short, occasionally almost without any at all. It attains a very large size, and the wood is tolerably straight-grained and pretty free from knots, in many instances resembling the German species called wainscot. It is easily split for making laths for plasterers and slaters, and is beyond doubt the best sort for joist, rafters, and other purposes where stiff and straight-grained timber is a desideratum. In the Quercus Sessiliflora, which, though found about Dulwich and Norwood, according to Miller, appears to be the common oak of Durham, and perhaps of the north of England, the leaves have long footstalks, frequently an inch in length, and their sinuosities are not so deep, but are more regular than those of the Robur just described. The acorns are so close to the branches as to have scarcely any stalks. The wood is of a darker hue, and the grain is so smooth that it resembles chesnut. Than the Robur it possesses more elasticity, hardness, and weight, but in seasoning it is subject to warp and split; hence unfit for laths, which in the north of England are rarely of oak. There is no reason for supposing, as has been conjectured, that the oak of the Gothic roofs of the country is of this species, though we are aware of the great durability of the oak in the buildings in the northern part of the island.

1687. The specific gravity of the species first named, that is, the Quercus Robur, may be taken at about ·800, and the weight of a cube foot 50·45 lbs. That of the last-named at ·875, and the weight of a cube foot at about 55·00 lbs. Their cohesive force and toughness are proportionable.

1688. The American species scarcely claim a notice here, because their use in England is, from every circumstance, out of the question. Of the red oak of Canada (Quercus rubra), the only one of which the use could be contemplated, we merely observe, that it is a light, spongy, and far from durable wood, though, in the country, in many instances useful. Its growth is rapid, and it rises to the height of 90 or 100 feet.

1689. There is a species of oak imported from Norway, which has received the name of *clapboard*, and another imported from Holland, known under the name of *Dutch wainscot*, though grown in Germany, whence it is floated down the Rhine for exportation. The latter is destitute of the white streaks which cross the former, and is thereby distinguished from it. The use of these woods has latterly much diminished in England. They are both softer than common oak, and the clapboard far inferior to wainscot. They are more commonly used for fittings and fixtures, whereto they are well adapted. In damp situations, oak decays gradually from its external surface to the centre of the tree; the ring on the outside, which it acquired in the last year of the growth of the tree, decaying first; but if the tree be not felled till past its prime, its decay is reversed by its commencement at the centre. An oak rarely reaches its prime under the age of an hundred years; after that period, which is that of its greatest strength, it cannot be considered as fit for building purposes; and, indeed, it may be taken as a rule, that oak before arriving at its maturity is stronger than that which has passed it.

1690. If the architect has the opportunity of selecting the timber whilst in a state of growth, he will, of course, choose healthy, vigorous, and flourishing trees. Those in which the trunks are most even are to be preferred. A mark of decay is detected in any swelling above the general surface of the wood. Dead branches, especially at the top of the tree, render it suspicious, though the root is the best index to its soundness. The notion of Alberti (*De Re Ædificatoria*), of using all the timber in the same building from

the same forest, is a little too fanciful for these days. though we confess we have some misgivings in impugning an authority which, in most other respects, we are inclined to receive with the highest veneration.

1691. In felling not only the oak, but all other large trees, the great branches should be first cut off, so that the tree may not be injured or strained in its fall; and the trunk, moreover, must be sawed as close to the ground as possible. When felled, but not before, it is to be barked, trimmed of its branches, and left to season. Before, however, leaving it for this purpose, it is considered by workmen better to square it, which, it is thought, prevents its tendency to split. If to be employed for posts or bearing pieces, boring it has been employed with success; but it is needless to observe, that in pieces subject to transverse strains such a practice is not to be recommended.

1692. The pieces selected for building must be chosen with the straightest grain; but there are pieces which are occasionally employed, as for knees and braces, wherein a curvilinear direction of the fibres of the timber is extremely desirable. It may, however, be generally stated, that, in the case of two equal-sized and seasoned pieces, the heavier is the piece to be preferred.

1693. In oak, as in all other woods, the boughs and branches are never so good as the body of the tree; the great are stronger than the small limbs, and the wood of the heart stronger than all. When green, wood is not so strong as when thoroughly dry, which it rarely is till two or three years after it is felled. It is scarcely necessary to say, that, containing much sap, it is not only weaker, but decays sooner. It is weakened by knots, at which, in practice, it is found that fractures most frequently occur; and it is important to the architect to recollect that he should always reject cross-grained pieces.

1694. The great use of oak in this country is more for ship-building purposes than for architectural, its use, except in the provinces, being principally confined to pieces which are much liable to compression, or where great stiffness is required, or in pieces like sills to windows and door-cases, where there is much alternation of dryness and damp. So early as 1788, the consumption of oak for ship-building purposes was, in that year upwards of 50,000 loads.

1695. When of good quality, it is more durable than any other wood which is procurable of a like size. In a dry state, it is ascertained to have lasted nearly a thousand years. The open-fibred porous oak of Lincolnshire, and some other places, is a bad sort. The best is that with the closest grain and the smallest pores. The colour, as is well known, is a fine brown; that which partakes of a reddish hue is not so good as the other. The smell of it is peculiar; it contains gallic acid, and it assumes a black purple colour when damp, by contact with iron. It warps and twists much in seasoning, and shrinks in width about one thirty-seventh part.

1696. CHESNUT. One of the finest of the European timber trees, the *Fagus castanea* of botanists, was heretofore so common in this country, that Fitzstephen, in his description of London about the time of Henry II., mentions a fine forest of chesnuts as growing on the northern side of the city. It is stated to have been used in the buildings of our ancestors, but it is very doubtful if it was so employed. The young tree vies with the oak in durability, from the small proportion of sapwood it contains. Of its durability, the roofs of Westminster Hall, that of King's College, Cambridge, and that of Notre Dame, at Paris, are cited as examples, though the fact of the latter being of chesnut is doubted by Rondelet, who says that Buffon and D'Aubenton thought it a species of oak, which is now well known to be the case in the roof first named.

1697. Chesnut, however, is not to be trusted like oak. As Evelyn observed, it is often well-looking outside, when decayed and rotten within. Belidor says it soon rots when the ends of timbers of it are closed round in a wall.

1698. It is, perhaps, from the circumstance of its colour so nearly resembling that of oak, that one timber has so often been mistaken for the other. The difference, however, is, that the pores of the sapwood of the oak are larger and more thickly set and easily distinguished, whilst those in the chesnut require magnifying powers to be distinguished. But a more decided difference is, that the chesnut has no large transverse septa. It is far easier to work than oak, and is not very susceptible of swelling and shrinkage. From what has been mentioned above, it may be inferred that the wood, though tough and compact, is, when young, hardest and most flexible, the old wood being often shaky and brittle.

1699. Water pipes of this tree endure much longer than those of elm; and for tubs and vessels to hold water, it is superior to oak; for when once thoroughly seasoned, it will neither shrink nor swell, on which account it is used by the Italians for wine tuns and casks. It will thrive on most soils, but rather delights in a rich loamy land, succeeding well, also, on that which is gravelly, clayey, or sandy. Mixed soils are suitable to it, and it is found in the warmer mountainous situations of most parts of Europe.

1700. From the experiments, the cohesive force of a square inch of chesnut, when dry varies from 9570 to 12,000 lbs., and the weight of a cubic foot, when dry, is from 48 to 55 lbs.

1701. Beech (*Fagus Sylvatica*). A beautiful tree, growing to a considerable height, and carrying a proportionable trunk. It flourishes most in a dry warm soil, and grows moderately quick. The wood is hard, close, has a dry even grain, and, like the elm, bears the drift of spikes. The sorts of beech are the brown or black, and the white beech. It is common throughout Europe. In the southern parts of Buckinghamshire, where the soil is chalky, it is particularly abundant; and such is the case near Warbleton, in Sussex, on the southern range of chalk hills, where the beeches are very fine,

1702. Constantly immersed in water, the beech is very durable; such also is the case with it when constantly dry; but mere damp is injurious to it, and it is very liable to injury by worms, though to these Duhamel considers it much less liable when water-seasoned, than when seasoned in the common way. To render it less liable to the worm, it has been recommended to fell it about a fortnight after Midsummer, to cut it immediately into planks, which are to be placed in water about ten days and then dried. Beech is little used in building, except for piles, in which situation, if constantly wet, they are very durable. From its uniform texture and hardness, it is a good material for tools and furniture, and of it, in boards and planks, large quantities are brought to London. It is without sensible taste and smell, easy to work, and susceptible of a very smooth surface. The white sort is the hardest, though the black is tougher, and, according to Evelyn, more durable. The weight of a cube foot varies from 43 to 53 pounds.

1703. Walnut (*Juglans, quasi Jovis glans*) is of several sorts. The Juglans Regia, or common walnut, was formerly much cultivated in this island, as well for the sake of its timber as of its fruit. On the former account the importation of mahogany has long since rendered its cultivation less common. It flourishes better in a thin limestone soil, than in one that is rich and deep, and, if raised for timber, should not be transplanted, but remain in the place where it is sown. For furniture, from its rich brown colour, it is by many persons preferred to mahogany. Its scarcity renders its employment rare for building purposes, though by the ancients it was so employed. One of its properties is, that it is less liable to be affected by worms than any other timber, cedar only excepted; but from its brittle and cross-grained texture, it is not generally useful for the main timbers of a building.

1704. The heart-wood is of a greyish brown with dark brown pores, often veined with darker shades of the same colour, which are much heightened by oiling. The texture is not so uniform as that of mahogany, nor does it work so easily, but it may be brought to a smoother surface. The weight of a cubic foot is about 45 pounds.

1705. Cedar (*Pinus Cedrus*) is an evergreen cone-bearing tree, of which though several have been grown in this country, it is too scarce to be employed in building. Its durability is very great; such, indeed, that Pliny states cedar to have been found in the Temple of Apollo at Utica, which must have been 1200 years old. Its colour is a light rich yellow brown, with the annual rings distinct. It is resinous, and has a powerful smell. The taste is slightly bitter, and it is not subject to worms. It is very straight in the grain, works easily and splits readily. Weight of a cubic foot from 30 to 38 pounds.

1706. Fir (*Pinus Sylvestris*). The red or yellow fir is produced on the hills of Scotland; but the forests of Russia, Denmark, Norway, Lapland, and Sweden produce the finest timber of this species. It is imported, under the name of red wood, in *logs* and *deals*. From Norway the trees are never more than 18 inches diameter, whence there is much sap-wood in them; but the heart is a stronger and more durable wood than is had from larger trees of other countries. From Riga a great deal of timber is received under the name of *masts* and *spars*: the former are usually 70 or 80 feet in length, and from 18 to 25 inches diameter; when of less diameter they take the latter name. Yellow deals and planks are imported from Stockholm, Frederickshall, Christiana, and various other parts of Sweden, Russia, Norway, and Prussia. Of the pine species the red or yellow fir is the most durable; and it was said by the celebrated Brindley, that red Riga deal, or pine wood, would endure as long as oak in all situations. In Pontey's *Forest Pruner*, on the authority of Dr. Smith, an instance is given of the durability of natural-grown Scotch fir. It is therein stated, that some was known to have been 300 years in the roof of an old castle, and that it was as fresh and full of sap as timber newly imported from Memel, and that part of it was actually wrought up into new furniture. It is to be observed, that foreign timber has an advantage too seldom allowed to that which is grown at home, the former being always in some degree seasoned before it arrives in this country, and therefore never used in so unseasoned a state as the latter timber usually is.

1707. From its great lightness and stiffness it is superior to any other material for beams, girders, joists, rafters, and framing in general. In naval architecture it is used for masts and various other parts of vessels. In joinery, both internal and external, it stands better, is nearly as durable as oak, and is much cheaper.

1708. There is great variety in the colours of the different sorts of this fir: it is generally of a red or honey yellow of different degrees of brightness, and consists in section of hard and soft circles alternately, one part of each annual ring being soft and light coloured, the

other harder and dark coloured, and possessing a strong resinous taste and smell. When not abounding in resin it works easily. That from abroad shrinks in the log, from seasoning, about one thirtieth part of its width.

1709. The annual rings of the best sort of this timber do not exceed one tenth of an inch in thickness, their dark parts are of a bright red colour. That from Norway is the finest of the sort, to which the best Riga and Memel are much inferior. The inferior timber of this kind, which is not so durable nor so capable of bearing strains, has thick annual rings, and abounds with a soft resinous matter, which is clammy and chokes the saw. Much of the timber of this sort is from Sweden, but it is inferior in strength and stiffness. That which is produced in the colder climates is superior to that which is the product of warmer countries, the Norway timber being much harder than that of Riga. The weight of a cubic foot of this fir, when seasoned, varies from 29 to 40 pounds. That of English growth, seasoned, from 28 to 33.

1710. WHITE FIR (*Pinus abies*), commonly called the spruce of Norway, whose forests produce it in abundance. This is the sort which in deals and planks is imported from Christiana, in which condition it is more esteemed than any other sort. The trees from which these are generally obtained are of 70 or 80 years' growth, and are usually cut into three lengths of about 12 feet each, which are sawn into deals and planks, each length yielding three deals or planks. Their most usual thickness is 3 inches, and they are generally 9 inches wide. In this country they are sold by the hundred, which in the case of white as well as yellow deals, contains 120 deals, be their thickness what it may, reduced to a standard one of an inch and a half, a width of 11 inches, and a length of 12 feet. That is called whole deal is an inch and a quarter thick, and slit deal is one half of that thickness. It unites better by means of glue than the yellow sort, is used much for interior work in joinery, and is very durable when in a dry state.

1711. The colour of the spruce fir is a yellow or rather brown white, the annual ring consisting of two parts, one hard, the other softer. The knots are tough, but it is not difficult to work. Besides the importation above named, there is a considerable quantity received from America. Of the Christiana fir a cubic foot weighs from 28 to 32 pounds when seasoned. That from America about 29 pounds; and the Norway spruce grown in Britain about 34 pounds. In seasoning it shrinks about a seventieth part, and after being purchased as dry deals at the timber yards, about one ninetieth.

1712. AMERICAN PINES. The *Pinus Strobus*, or what is called the Weymouth or white pine, is a native of North America, imported in logs often more than 2 feet square and upwards of 80 feet in length. It is an useful timber, light and soft, stands the weather tolerably well, and is much used for masts. For joiners' work it is useful from its clean straight grain. But it should not be used for large timbers, inasmuch as it is not durable, and is moreover very susceptible of the dry rot. Its colour is a brown yellow, and it has a peculiar odour. The texture is very uniform, more so, indeed, than any other of the pine species, and the annual rings are not very distinct. It stands well enough when well seasoned. A cubic foot of it weighs about 29 pounds.

1713. The yellow pine, or *Pinus variabilis*, is imported into England, but it is not much used; it is the produce of the pine forests from New England to Georgia.

1714. The pitch pine (*resinosa*), remarkable for the quantity and fragrance of the resin it produces, is a native of Canada. It is brittle when dry, and, though heavy, not durable. It is of a much redder hue than the Scotch pine, and from its glutinous property difficult to plane. The weight of a cubic foot is 41 pounds.

1715. The silver pine (*picea*) is common in the British plantations. This species of timber is produced in abundance, and is much used on the Continent both for carpentry and ship-building. It is light and stiff, and according to Wiebekin, lasts longer in air than in water. A cubic foot weighs about 26 pounds.

1716. The Chester pine (*pinaster*) is occasionally cultivated in the British plantations. It is better suited to water than exposure to the air, and has a finer grain, but contains less resin, than the pine or silver fir. A cubic foot weighs about 26 pounds.

1717. LARCH (*Pinus Larix*). A timber tree only lately to any considerable extent adopted in the plantations of Great Britain, among whose cultivators the Duke of Athol has been one of the most ardent and successful. It grows straight and rapidly, is said to be durable in all situations, and appears to have been known and appreciated by Vitruvius, who regretted the difficulty of its transport to Rome, where, however, it was occasionally used. Wiebekin prefers it to the pine, pinaster, and fir, for the arches of timber bridges. To flooring boards and stairs, where there is much wear, it is well suited, and when oiled assumes a beautiful colour, such, indeed, that when used for internal joinery, a coat of varnish gives it a more beautiful appearance than it could receive from any painting. The American larches do not produce turpentine; but the timber has been considered equal to the European sorts. It is of a honey yellow colour, and more difficult to work than the Riga or Memel timber, though, when obtained, the surface is better. It bears the driving

to nails and bolts, and stands well if properly seasoned. A cubic foot weighs from 30 to 40 pounds.

1718. Poplar. The *Populus* of botanists, whereof five species are grown in England: the common white poplar, the black, the aspen or trembling poplar, the abele or great white poplar, and that of Lombardy. The wood of this tree is only fit for the flooring of inferior rooms where there is not much wear. Evelyn attributes to this wood the property of burning "*untowardly*," rather mouldering than maintaining any solid heat. Its colour is a yellow or brown white. The annual rings, whereof one side is a little darker than the other, making each year's growth visible, are of an uniform texture. The best sorts are the Lombardy, the black, and the common white poplar. Of the Lombardy poplar, the weight of a cubic foot is about 24 pounds; of the aspen and black poplar, 26 pounds; and of the white poplar, about 33 pounds.

1719. Alder (*Betula alnus*). A tree delighting in wet places by the banks of rivers, and which furnished the material, says Vitruvius, for the piles whereon the whole of the buildings of Ravenna stand. In a dry situation it is unfit for employment, on account of its early rot when exposed to the weather or to mere damp, and its susceptibility of engendering worms. Evelyn says that it was used for the piles upon which the celebrated bridge of the Rialto at Venice was founded in 1591; but we have no certain data by which such assertion can be maintained. There is, however, no doubt that it may be advantageously employed in situations where it is constantly under water.

Its colour is of a red yellow, of different shades, but nearly uniform; which latter quality is exhibited in its texture.

From its softness it is easily worked, and seems adapted, therefore, for carving. In a dry state the weight of a cubic foot varies from 36 to 50 pounds.

1720. Elm (*Ulmus*). In Great Britain five species of this tree abound, wher the *Ulmus campestris*, common in the woods and hedges of the southern parts of Engla is a hard and durable wood, but is rarely used except for coffins. The *Ulmus suber* or cork-barked elm, is an inferior sort, and is very common in Sussex.

1721. The *Ulmus Montana* is the most common species in Europe, and particularly the northern counties of England. It is more generally known by the name of the broad-leaved elm or wych hazel. Without enumerating the other varieties, whereof the Dutch elm (*Ulmus major*) is good for nothing, we shall merely observe, that the *Ulmus glabra*, common in Herefordshire, Essex, and the north and north-eastern counties of England, grows to the largest size and is most esteemed, whilst the Dutch elm is the worst. The elm is a durable timber when constantly wet, as a proof whereof we have only to mention that it was used for the piles on which the old London Bridge stood. Indeed, its durability under water is well known; but for the general purposes of building it is of little value, and it rarely falls to the lot of the architect to be obliged to use it.

1722. The colour of the heart-wood is darker than that of oak, and of a redder brown. The sapwood is of yellow or brown-white colour. It is porous, cross and coarse grai has a peculiar smell, twists and warps very much in drying, and shrinks considerabl breadth and length. Though difficult to work, it bears the driving of bolts and n better than most other sorts of timber. The weight of a cubic foot, when dry, varies f 36 to 48, seasoned from 37 to 50 pounds. From experiment it seems that in seaso it shrinks one forty-fourth part of its width.

1723. Ash (*Fraxinus excelsior*). This, the most valuable of the genus, is com throughout Europe and the northern parts of Asia. It grows rapidly, and of it the yo is more valuable than the old wood. It is much affected by the difference of the soils which it grows. It will not endure when subject to alternations of damp and moistur though sufficiently durable when constantly in a dry situation. Its pores, if cut in the spring, are of a reddish colour, and it is improved by water-seasoning. Evelyn says, that when felled in full sap, the worm soon takes to it; and therefore recommends its being felled in the months from November to February. The texture is compact and porous the compact side of the annual ring being dark in colour, whence the annual rings ar distinct. The general colour is brown, resembling that of oak; but it is more veine and the veins darker than those of oak. The timber of the young tree is a white, ap proaching brown, with a greenish hue. It has no peculiar taste or smell, is difficult to work, and is too flexible for use in building, beside the important want of the character o durability. The weight of a cubic foot varies from 35 to 52 pounds; and it is to be observed, when the weight is much less than 45 pounds the timber is that of an old tree.

1724. Sycamore (*Acer pseudo-platanus*), usually called the plane tree in the northern part of the island, is common in Britain and on the mountains of Germany. It is rapid in growth, and the wood is durable when it escapes the worm, to which it is quite as liabl as beech. The use of it in buildings is not common, but for furniture it is valuable. Th colour is a brown white, yellowish, and sometimes inclining to white. Texture uniform; annual rings indistinct. It is not so hard as beech, brittle, and generally easy to work. A cubic foot, when seasoned, weighs from 34 to 42 pounds. Ware says that there are old

houses in this country floored with sycamore and wainscoted with poplar. It seems well enough calculated for floors.

1725. BIRCH. *Betula alba*, or common birch, is a species of alder, to which article the reader is referred (1719). The American birch, from Canada, is but little superior to the European birch. The Russian birch, on account of its clean light colour and silvery grain, has been for many years extensively employed for bedroom furniture.

1726. A description of fir (*Wellingtonia gigantea*) has been lately introduced from our colony of Victoria, in Vancouver's Island, on the western side of North America. It is sent in logs, deals, and planks. Instead, however, of being only 14 to 16 inches square, and 60 feet long at the maximum, as in the case of Baltic timber, one stick of this timber has been sent not less than 127 feet long, and about 42 inches square at one third of the height measuring from the butt end, which end was about 50 inches square. It contained 1307 cubic feet of timber; this is not an exceptional size. A tree is reported to have been cut down lately, the circumference of which was 90 feet, and its height 325 feet; the bark was in some places 4 feet thick. The tree, sound and solid, contained 250,000 feet of timber. It was supposed to be 3,100 years old. G. R. Burnell states the tenacity of this timber to be greater than, and its resistance to a crushing weight apparently superior to, Baltic timber. When loaded in the centre to the point of instantaneous rupture, the Vancouver's island wood bore weights which were to those borne by English oak as 13 to 12, and to those borne by the Baltic fir as 13 to 8. Three-inch cubes of the three woods were subjected to weights of 45 tons each, or 5 tons (11,240 lbs.) on the inch superficial, when the permanent elasticity of oak was not affected, that of the fir only slightly so, whilst the Baltic timber was permanently and perceptibly compressed.

1726*a*. For joiner's work, the straightness, freedom from knots, deep warm colour, and beauty of the grain, places this timber above any other of the fir or pine woods; whilst its greater hardness would in staircases, floors, &c., compensate for any slight increase in the price of labour for working it. It has been employed by Mr. Burnell in the joiner's work of an office in Lincoln's Inn Fields. It seems to affect iron somewhat as does oak.

1727. MAHOGANY (*Swietenia Mahogoni*) is a native of the West Indies and the country round the Bay of Honduras. The tree is said to be of rapid growth; its trunk often exceeds 40 feet in length and 6 feet in diameter. Its Spanish name is *caôba*. *Spanish* mahogany is imported from Cuba, Jamaica, Hispaniola, St. Domingo, and some other of the West India Islands and the Spanish Main. The best quality is considered to come from the sea-board on the south part of the island of San Domingo or Hayti. The logs are from 20 to 26 inches square, and about 10 feet in length. It is close grained, hard, sometimes strongly figured, and generally of a rich brown colour, darker than Honduras; but its pores frequently appear as if chalk had been rubbed into them. It takes a very high polish with hand labour; and French polishing brings out its flower with great lustre.

1727*a*. *Honduras* mahogany is imported in logs of larger size than the above, that is, from 2 to 4 feet square, and from 12 to 18 feet in length; logs 40 feet in length have been obtained; planks 6 to 7 feet wide are occasionally imported; but 5 feet square and 15 feet long are the more ordinary dimensions. It is so distinctly inferior to the Spanish quality, that no ordinary judge can possibly be mistaken in the normal samples. In weight it is lighter; and it is of a straighter and more open or spongy grain, without much flower, and therefore little sought after by cabinet-makers. The worst kinds are those most filled with grey specks, from which Spanish mahogany, except the Cuba, is comparatively free.

1727*b*. Spanish mahogany is in this country far too valuable to be used in common building. It sometimes sells for as much as 6*l*. per foot cube, when good fir, of nearly equal value for such purposes, would only cost 2*s*. at the maximum. In Jamaica, mahogany has been frequently employed for floors, joists, rafters, shingles, &c.; and ships have been built of it; for which last purpose, the circumstance of its allowing shot to be buried in it without splintering, makes it peculiarly suitable. Soon after its introduction into this country in 1724, when a specimen was sent to Dr. Gibbons by his brother, a West India captain, it was employed for doors, as at the Treasury, by W. Kent, in 1733. The better qualities are reserved for small articles of cabinet-work and furniture, the best being employed in the form of veneers, of which twenty-one cuts are now got out of an inch thickness. Solid work for more general purposes, such as handrails of stairs, sashes, sash-doors, and ordinary counting-house and office fittings, &c., is worked out of Honduras mahogany, which is also employed as the groundwork for veneers of the finer quality.

1727*c*. It is generally sold at per foot superficial, one inch thick; the common qualities at 5*s*. to 5*s*. 6*d*. per cubic foot. It holds with glue better than any other wood. Of Honduras mahogany, the quality called 'common southern' weighs about 26 lbs.; 'superior northern' about 42½ lbs.; 'good northern' about 32 lbs; and 'common northern' about 36 lbs., per cubic foot. All these qualities are used in shipbuilding; the lightest, for furniture. Spanish mahogany weighs 48 lbs. 6 oz., the best from 50 lbs. to 54 lbs. per cubic foot. All kinds of this timber are said to be very durable, and free from the attack of worms when kept constantly dry. They do not warp or crack under the influence of

the sun, but they do not resist alternations of great wetness and dryness. They shrink but little in drying, and twist and warp less than any other wood.

1727*d*. *African* mahogany (*Swietenia* or *Khaya Senegalensis*), from Gambia, is a more recent importation; it twists much more than either of the above, and is decidedly inferior to them in all respects except hardness. Small quantities of mahogany are also received from Jamaica and the other West India islands, but they are of a quality so inferior even to the Honduras variety, that they are practically unknown to timber merchants. Florida *cedar* and other varieties are frequently made to pass as mahogany in cheap works.

1728. Teak (*Tectona grandis*), has of late years formed a valuable timber for shipbuilding; and to a small extent in house, and even carriage, joinery. The best varieties are obtained from the ports of Rangoon or Moulmein (called Moulmein teak), and from the coast of Malabar (called East Indian teak). It is by no means rare to meet with sticks of perfectly straight teak 60 or 70 feet long and about 24 to 30 inches square. The wood is of a light brown colour, porous, very hard, tough, and when sound, of great strength and tenacity. It derives much of its value from the aromatic oily substance with which it is more or less saturated in the fresh state; but this does not prevent its attack by insects whilst in the forest, consequently the trees turn out to be very defective. The wood works well; takes a good polish, and though porous, it is very durable in exposed situations: it is considered that its oily properties render it less injurious to iron than oak. The tenacity of Moulmein teak is 15,000 lbs. per superficial inch. Some fine planks from Rangoon were nearly $3\frac{1}{2}$ feet wide.

1728*a*. Morung saul (*Shorea robusta*), of Nepaul, in the East Indies, is in great repute for shipbuilding. It is a heavy, close-grained, light brown wood. This timber is considered to be the most valuable and extensively used of all the trees of India, but the value of it is much diminished from the injudicious mode in which it is squared. The *saul* or *sâl* timber brought to Calcutta is seldom more than 30 feet in length. In strength and tenacity it is considerably superior to the best teak, compared with which, Captain Baker's experiments prove that its strength is about as 1121 to 869. From Major H. Campbell's experiments, unseasoned saul broke with a weight of 1308 lbs.; seasoned saul with 1319 lbs.; and teak wood with 1091 lbs. Considered as a building wood, it is somewhat apt to shrink unless very well seasoned, (*Juror's Reports*, 1851).

1728*b*. Morra (*Mora excelsa*), sometimes called Demerara locust, is sent from Demerara in South America. It is a valuable timber for shipbuilding.

1728*c*. Greenheart (*Laurus chloroxylon*, or *Nectandra rodiæi*), imported from the English colony of British Guiana, and Brazil, possesses the reputation of immunity from the attacks of marine boring worms; and for this reason it is now largely used in hydraulic works. Mr. Burnell has stated his conviction from what he saw, especially of two logs, in the West India Docks in 1860, that this timber does suffer from the attacks of land insects; and he was at that time in possession of a piece of the timber from Victor Bay, Panama, which was completely riddled by the *Teredo navalis*. A writer, commenting on this statement, says that "his experience proves that greenheart is exempt from the therosion by the *teredo*, but that a mollusc is found alive in it when arriving here from the West Indies. The worm is found in sizes from the *lymexylon* to the *teredo*, but it is of a different species, and seems not to live when this wood is used in such constructions as dock gates, in this country." The timber squares from 18 to 24 inches, but usually arrives about 16 inches square and 70 feet in length. It is a hard, heavy, fine, but not even-grained wood; it proves strong and durable in positions that are alternately wet and dry.

1728*d*. Among the other useful hard woods are:—I. The Peon, or *Poon wood*, an Indian wood of Travancore, East Indies, formerly imported to some extent, from 2 to 4 feet in circumference and 80 feet in length; but latterly it has been regarded with such disfavour that it is now hardly ever imported. II. The Kowrie, a New Zealand wood. III. The Australian Red Cedar. IV. The Sabicue, from Cuba, which was used for the steps of the stairs in the Great Exhibition building of 1851, and are now in the Crystal Palace at Sydenham. It makes excellent beams and planks. A heavy specimen obtained of this wood was "a portion of a large beam, which broke merely in falling from a truck!" V. The Iron Bark, of Van Diemen's Land, Australia, is a very hard and compact wood, with a specific gravity heavier than water. VI. Borneo wood, imported from Sarawak, was used in 1865 for the floors and staircase in a warehouse in Gresham Street West. It is of so peculiar a character that it broke nearly all the saws used to reduce it to battens: it is light brown in colour, with a texture very similar to teak. It may probably be the *Bilian*, or iron wood of that country, said to be impervious to the attacks of the white ant. It has not been known to decay when immersed either in fresh or salt water. An engineer who had resided in Borneo for five years, states he had never seen a rotten piece of *Bilian* wood.

1728*e*. Besides the weights of various woods given in the text (as marked *) the subjoined list of the weight per foot cube in pounds avoirdupois, may be useful.

1728*f*. The chief woods employed in shipbuilding and acknowledged as "first-rate" by the authorities at Lloyds, are eight in number. These are, I. English oak; II. American live oak; III. African oak; IV. Morung Saul; V. East Indian Teak; VI. Greenheart; VII. Morra; and VIII. Iron Bark.

1729. In timber yards, deals are sold by the long hundred or six score; thus the "standard" of deals is reckoned as 120—12 ft. × 1½ in. × 11 ins., but varying lengths and thicknesses are imported (See par. 2362 and 2363).

Names.	No.	Ft. long.	Ins. thk.	Wide.	Sup. ins.	Cube ft.
Petersburg deals - -	120	12	1½	11	1980 of 1″	165

The measurements have been reduced to one standard of 12 ft. long, 3 in. thick, and 9 in. wide. Two of the latest works for calculating deals according to this, the Petersburg standard hundred, are, J. Smith, *Companion to Hoppus; Handbook of Tables for the use of Timber Merchants, &c.*, London, 1860; and Grandy, *Timber Importers', &c. Standard Guide*, 8vo., London, 1865, to which latter work we are glad to refer the student, and from which we select the following extracts:—

1729*a*. "American Ports.—At *Quebec*, there are three qualities of spruce deals, 1st, 2nd, and 3rd. Irregular size scantlings are scarcely ever shipped from this port, the general run being battens, 7 × 3; deals, 9 × 3; and planks, 11 × 3, 7 × 2, 9 × 2, and 11 × 2; general lengths from 8 to 14 feet. All under 8 feet are classed as "ends." Yellow pine battens, deals, and planks are shipped as 1st, 2nd, and 3rd qualities. Battens are not so valuable as deals and planks, some of the latter running 11 to 30 inches; the finer qualities bear a high rate.

1729*b*. *St. John's* deals rank after those of Quebec in quality. Battens, deals, and planks run from 8 to 26 feet; all lengths under 8 feet being classed as ends. All deals are scarcely ever classed into 1st, 2nd, and 3rd, but taken by the run; the sizes 7 × 3, 9 × 3, and 11 × 3, being the highest in price. Irregular scantlings, such as 3 × 3, 4 × 3, 6 × 3, 5 × 2½, &c., are less per thousand.

1729*c*. *Pugwash, Miramichi, and other Lower Ports.* Battens, deals, and planks are obtained as at St. John's. The deal is a closer grain, but coarser, and hence not so valuable. The lengths run from 8 to 14 feet, all under 8 feet being 'ends.' Scarcely any irregular scantlings are shipped from these ports. The square timber at the American ports is generally purchased by the cubic foot.

1729*d*. Baltic Ports.—*Memel.* Battens and deals are scarce; planks form the bulk of the timber imported. They all run from 8 to 20 feet. They are generally sold by 720 feet run of 11 × 3, = 1 Petersburg standard. Battens and deals run 7 × 3 and 9 × 3. *Christiania.* Battens and deals, and *Drammen* deals run 9 × 3, 7 × 3, or 7 × 2½. *Crown Memel.* Square timber is generally sold by the 50 running feet, as 1st middling, and 2nd middling. But "undersized" timber, that is, under 12 inches square, is sold by 50 cubic feet, or by 50 running feet. There are also "short lengths of undersized" timber.

1729*e*. Home Trade.—At *London*, pine deals are sold by the Petersburg, and spruce deals by the London, standard. Square timber is sold by the load, or 50 cube feet, or by the cube foot, calliper measurement. At *Liverpool and Bristol*, deals are sold by the Petersburg standard; square timber by the load or foot, string measurement. At *Glasgow*, deals are sold by the cube foot; square timber by the cube foot, string measurement. At *Dublin*, deals are sold by the London or Dublin standard of 120, 12 × 9 × 3; square timber by the ton of 40 feet, string measurement."

1729*f*. These timbers are used in building for the undermentioned purposes:—
Joists and main timbers: The largest, of Dantzic, Memel or Riga, fir; those of 10 or 12 inches square, from Sweden; those of 8 inches square, from Norway.

Partitions and minor timbers: American red wood or red pine, which not being so strong as that from the Baltic, must be cut to a little larger size.
Sleepers, window sills, and some parts of the roof: Oak.
Framing: Norway and Christiania white deals; Christiania yellow deals are sappy; Swedish deals are bad, as they warp much.
Panelling: Christiania white pine; or American yellow pine.
Best ordinary floors: Drammen and Christiania white deals; American pitch pine; American deals are bad for floors, as they are a softer wood.
Ground floors: Stockholm and Gefle yellow deals.
Warehouse floors, and Staircases: Archangel and Onega planks, and American pitch pine.
Best floors: Petersburgh, Onega, and Christiania battens.
Interior finishings generally: Baltic red and white wood, and American red and yellow pine.

1729*g*. Memel timber is generally considered the most convenient for size, and is superior in strength to the Swedish, or Norwegian; Riga, the best in quality; Dantzic, when free from large knots, the strongest; and the Swedish, the toughest, but weakest. Riga can always be depended upon, and although the dearest in price, is the cheapest in the end.

1730. We shall now place before the reader, observations on timber made by the celebrated Evelyn though perhaps at the risk of repetition in what follows after them.

1731. "Lay up your timbers very dry, in an airy place, yet out of the wind or sun, and not standing very upright, but lying along, one piece upon another, interposing some short blocks between them, to preserve them from a certain mouldiness which they usually contract while they sweat, and which frequently produces a kind of fungus, especially if there be any sappy parts remaining.

1732. "Some there are yet who keep their timber as moist as they can by submerging it in water, where they let it imbibe, to hinder the cleaving; and this is good in fir, both for the better stripping and seasoning; yea, not only in fir, but other timber. Lay, therefore, your boards a fortnight in the water (if running the better, as at some mill-pond head); and there, setting them upright in the sun and wind, so as it may freely pass through them (especially during the heats of summer, which is the time of finishing buildings), turn them daily; and thus treated, even newly sawn boards will floor far better than many years' dry seasoning, as they call it. But, to prevent all possible accidents, when you lay your floors, let the joints be shot, fitted, and tacked down only for the first year, nailing them for good and all the next; and by this means they will lie staunch, close, and without shrinking in the least, as if they were all one piece. And upon this occasion I am to add an observation, which may prove of no small use to builders, that if one take up deal boards that may have lain in the floor a hundred years, and shoot them [plane their edges] again, they will certainly shrink (*toties quoties*) without the former method. Amongst wheelwrights the water seasoning is of especial regard, and in such esteem amongst some, that I am assured the Venetians, for their provision in the arsenal, lay their oak some years in water before they employ it. Indeed, the Turks not only fell at all times of the year, without any regard to the season, but employ their timber green and unseasoned; so that though they have excellent oak, it decays in a short time, by this only neglect.

1733. "Elm felled ever so green, for sudden use, if plunged four or five days in water (especially salt water), obtains an admirable seasoning, and may immediately be used. I the oftener insist on this water seasoning, not only as a remedy against the worm, but for its efficacy against warping and distortions of timber, whether used within or exposed to the air. Some, again, commend burying in the earth; others in wheat; and there be seasonings of the fire, as for the scorching and hardening of piles, which are to stand either in the water or in the earth.

1734. "When wood is charred it becomes incorruptible; for which reason, when we wish to preserve piles from decay, they should be charred on their outside. Oak posts used in enclosures always decay about two inches above and below the surface. Charring that part would probably add several years to the duration of the wood, for that to most timber it contributes its duration. Thus do all the elements contribute to the art of seasoning.

1735. "Timber which is cleft is nothing so obnoxious to reft and cleave as what is hewn; nor that which is squared as what is round: and therefore, where use is to be made of huge and massy columns, let them be bored through from end to end. It is an excellent preservative from splitting, and not unphilosophical; though to cure the accident painter's putty is recommended; also the rubbing them over with a wax cloth is good; or before it be converted the smearing the timber over with cow-dung, which prevents the effects both of sun and air upon it, if of necessity it must lie exposed. But, besides the former remedies, I find this for the closing of the chops and clefts of green timber, to anoint and supple it with the fat of powdered beef broth [we do not quite agree with our author here], with which it must be well soaked, and the chasms filled with sponges dipped into it. This to be twice done over.

1736. "We spake before of squaring; and I would now recommend the quartering of such trees as will allow useful and competent scantlings to be of much more durableness and effect for strength, than where (as custom is and for want of observation) whole beams and timbers are applied in ships or houses, with slab and all about them, upon false suppositions of strength beyond these quarters.

1737. "Timber that you have occasion to lay in mortar, or which is in any part contiguous to lime, as doors, window cases, groundsils, and the extremities of beams, &c., have sometimes been capped with molten pitch, as a marvellous preserver of it from the burning and destructive effects of the lime; but it has since been found rather to heat and decay them, by hindering the transudation which those parts require; better supplied with loam, or strewings of brick-dust or pieces of boards; some leave a small hole for the air. But though lime be so destructive, whilst timber thus lies dry, it seems they mingle it with hair to keep the worm out of ships, which they sheathe for southern voyages, though it is held much to retard their course.

1738. "For all uses, that timber is esteemed the best which is the most ponderous, and which, lying long, makes the deepest impression in the earth, or in the water being floated; also what is without knots, yet firm and free from sap, which is that fatty, whiter, and softer part called by the ancients *albumen*, which you are diligently to hew away. My Lord Bacon (Exper. 658.) recommends for trial of a sound or knotty piece of timber, to cause one to speak at one of the extremes to his companion listening at the other; for if it be knotty, the sound, says he, will come abrupt."

PRESERVATION OF TIMBER.

1739. The preservation of timber, when employed in a building, is the first and most important consideration. Wherever it is exposed to the alternations of dryness and moisture, the protection of its surface from either of those actions is the principal object, or, in other words, the application of some substance or medium to it which is imperviable to moisture; but all timber should be perfectly dry before the use of the medium. In Holland the application of a mixture of pitch and tar, whereon are strewn pounded shells, with a mixture of sea sand, is general; and with this, or small and sifted beaten scales from a blacksmith's forge, to their drawbridges, sluices, and gates, and other works, they are admirably protected from the effects of the seasons. Semple, in his work on aquatic building, recommends, that "after your work is tried up, or even put together, lay it on the ground, with stones or bricks under it to about a foot high, and burn wood (which is the best firing for the purpose) under it, till you thoroughly heat, and even scorch it all over; then, whilst the wood is hot, rub it over plentifully with linseed oil and tar, in equal parts, and well boiled together, and let it be kept boiling while you are using it; and this will immediately strike and sink (if the wood be tolerably seasoned) one inch or more into the wood, close all the pores, and make it become exceeding hard and durable, either under or over water." Semple evidently supposes the wood to have been previously well seasoned.

1740. Chapman (on the preservation of timber) recommends a mixture of sub-sulphate of iron, which is obtained in the refuse of copperas pans, ground up with some cheap oil, and made sufficiently fluid with coal-tar oil, wherein pitch has been infused and mixed.

1741. For common purposes, what is called *sanding*, that is, the strewing upon the painting of timber, before the paint dries, particles of fine sand, is very useful in the preservation of timber.

1742. Against worms we believe nothing to be more efficacious than the saturation of timber with any of the oils; a process which destroys the insect if already in the wood, with that of turpentine especially, and prevents the liability to attack from it. Evelyn recommends nitric acid, that is, sulphur immersed in aquafortis and distilled, as an effectual application. Corrosive sublimate, lately introduced under Kyan's patent, has long been known as an effectual remedy against the worm. Its poisonous qualities of course destroy all animal life with which it comes in contact; and we believe that our readers who are interested in preserving the timbers of their dwellings may use a solution of it without infringing the rights of the patentee. But the best remedy against rot and worms is a thorough introduction of air to the timbers of a building, and their lying as dry and as free from moisture as practicable. Air holes from the outside should be applied as much as possible, and the ends of timbers should not, if it can be avoided, be bedded up close all round them. This practice is, moreover, advisable in another respect, that of being able, without injury to a building, to splice the ends of the timbers should they become decayed, without involving the rebuilding of the fabric; a facility of no mean consideration.

1743. The worm is so destructive to timber, both in and out of water, that we shall not apologise for closing this part of our observations with Smeaton's remarks upon a species of worm which he found in Bridlington piers. "This worm appears as a small white soft substance, much like a maggot; so small as not to be seen distinctly without a magnifying glass, and even then a distinction of its parts is not easily made out. It does not attempt

to make its way through the wood longitudinally, or along the grain, as is the case with the common ship worm, but directly, or obliquely, inward. Neither does it appear to make its way by means of any hard tools or instruments, but rather by some species of dissolvent liquor furnished by the juices of the animal itself. The rate of progression is, that a three inch oak plank will be destroyed in eight years by action from the outside only." For resisting the effects of these worms, Smeaton recommends the piles to be squared, to be fitted as closely as possible together, and to fill all openings with tar and oakum, to make the face smooth, and cover it with sheathing.

1744. The destructive effects of the white ant are so little known here, that it is unnecessary to make further mention of them, than that in India they are the most inveterate enemies with which timber has to contend. From Young's *Annals* we extract the following curious statement of experiments made upon inch and a half planks, from trees of thirty to forty-five years' growth, after an exposure of ten years to the weather.

Cedar was perfectly sound.	Chesnut, very sound.
Larch, sap quite decayed, but the heart, sound	Abele, sound.
	Beech, ditto.
Spruce fir, sound.	Walnut, decayed.
Silver fir, in decay.	Sycamore, considerably decayed.
Scotch fir, much decayed.	Birch, worthless.
Pinaster, in a perfectly rotten state.	

Whence we may be led to some inference of the value of different sorts of timber in resisting weather; though we must not be altogether guided by the above table, inasmuch as it is well known that the soil on which timber is grown much increases or deteriorates its value, and that split timber is more durable and stronger than that which is sawn, from the circumstance of the fibres, on account of their continuity, resisting by means of their longitudinal strength; whereas when severed by the saw, the resistance depends more on the lateral cohesion of the fibres. Hence whole trees are invariably stronger than specimens, unless these be particularly well selected, and of a straight and even grain; but in practice the results of experiments are on this account the more useful.

DECAY OF TIMBER.

1745. If timber, whatever its species, be well seasoned, and be not exposed to alternate dryness and moisture, its durability is great, though from time it is known to lose its elastic and cohesive powers, and to become brittle if constantly dry. On this account it is unfit, after a certain period, to be subjected to variable strains: however, in a quiescent state it might endure for centuries. Dryness will, if carried to excess, produce this category. The mere moisture it absorbs from the air in dry weather is not sufficient to impair its durability. So, also, timber continually exposed to moisture is found to retain for a very long period its pristine strength. Heat with moisture is extremely injurious to it, and is in most cases productive of rot, whereof two kinds are the curse of the builder, the *wet* and the *dry* rot, though perhaps there be but little difference between the two. They appear to be produced by the same causes, excepting that the freedom of evaporation determines the former, and an imperfect evaporation the latter. In both cases the timber is affected by a fungus-like parasite, beginning with a species of mildew; but how this fungus is generated is still a *vexata quæstio*; all we know is, that its vegetation is so rapid, that often before it has arrived at its height, a building is ruined. From our inquiries on the Continent, we believe the disease does not occur to the extent that it does in this country; a fact which we are inclined, perhaps erroneously, to attribute to the use of the timber of the country, instead of imported timber. Our opinion may be fanciful, but there are many grounds on which we think that is not altogether the case. Our notion is, that our imported timber is infected with the seeds of decay long before its arrival here (we speak of fir more especially), and that the comparative warmth and moisture of the climate bring more effectually the causes of decay into action, especially where the situation is close and confined. Warmth is, doubtless, known to be a great agent in the dry rot, and most especially when moisture co-operates with it, for in warm cellars and other close and confined situations, where the vapour which feeds the disease is not altered by a constant change of air, the timbers are soon destroyed, and become perfectly decomposed.

1746. The lime, and more especially the damp brickwork, which receive the timbers of a new building, are great causes of decay to the ends of them; but we do not think that the regulations of the 19 Car. II. cap. 3., which directed the builders after the fire of London, to bed the ends of their girders and joists in loam instead of mortar, would, if followed out in the present day, be at all effective in preventing the decay incident to the ends of timbers. Timber, in a perfectly dry state, does not appear to be injured by dry lime; and indeed, lime is known to be effectual in the protection of wood against worms. Timber in contact with masonry is constantly found to decay, when the other parts of the

beam have been sound. This will be entirely obviated by inserting the wood in an iron shoe, or by placing a thin piece of iron betwixt the wood and the stone. Cases are known in which the iron shoe appeared to have proved a complete protection against dry rot and decay; a hard crust being formed on the timber in contact with the metal. The system of grouting must contribute to the early decay of wood bond; but at Manchester, where it was used very generally, it appeared to answer well, for the high temperature kept up in the buildings may cause the walls to dry very soon. Sea-sand, used for outside and inside purposes, in a spirit of economy, soon shows the result by inducing the appearance of rot in timber. Wood laid in sandy soil is well preserved, as was found to be the case in the specimens lately dug up at Birkenhead from depths varying from 8 feet to 32 feet; they were considered to have been buried for centuries.

1747. Nothing is more injurious to the floors of a building than covering them with painted floorcloth, which entirely prevents the access of atmospheric air, whence the dampness of the boards never evaporates; and it is well known that oak and fir posts have been brought into premature decay by painting them before their moisture had evaporated; whilst in the timber and pewing of old churches, which have never been painted, we see them sound after the lapse of centuries. Semple, in his *Treatise on Building in Water*, notices an instance of some field gates made of the fir of the place, part whereof, near the mansion, were painted, and had become rotten, while those more distant from the mansion, which had never been painted, were quite sound.

1747*a*. According to Baron Liebig, the decay of wood takes place in the three following modes:—I. The oxygen in the atmosphere combines with the hydrogen of the fibre, and the oxygen unites with the portion of carbon of the fibre, and evaporates as carbonic acid; this process is called decomposition. II. The actual decay of the wood which takes place when it is brought in contact with rotting substances. And III. The inner decomposition of the wood in itself, by losing its carbon forming carbonic acid gas, and the fibre under the influence of the latter is changed into white dust; this is called putrefaction.

PREVENTION OF DECAY.

1748. After timber is felled, the best method of preventing decay is the immediate removal of it to a dry situation, where it should be stacked in such a manner as to secure a free circulation of air round it, but without exposure to the sun and wind, and it should be rough squared as soon as possible. When thoroughly seasoned before cutting it into scantlings, it is less liable to warp and twist in drying. The ground about its place of deposit should be dry and perfectly drained, so that no vegetation may rise on it. Hence a timber yard should be strewed with ashes, or the scales from a foundry or forge, which supply an admirable antidote to all vegetation. It is thought that the more gradually timber is seasoned the greater its durability; and as a general rule, it may be stated, that it should not be used till a period of at least two years from its being felled, and for joiners' work at least four years. Much, however, is dependent on the size of the pieces. By some, water seasoning has been recommended; by others the steaming and boiling it; smoke-drying, charring, and scorching have also been recommended. The latter is, perhaps, the best for piles and other pieces that are to stand in the water or in the ground. It was practised by the ancients, and is still in use generally for the posts of park paling and the like.

1749. In Norway the deal planks are seasoned by laying them in salt water for three or four days, when newly sawed, and then drying them in the sun, a process which is considered to be attended with advantage; but it does not prevent their shrinking. Mr. Evelyn recommends the water seasoning for fir.

1749*a*. The effectual seasoning obtained by Davison and Symington's patent process of forcing heated air in a continued current through timber under pressure, effectually dries it, and coagulates the albumen. The timbers for the flooring of the Coal Exchange at London have been so treated, and show no signs of shrinkage. The wood was taken in its natural state, and in less than ten days it was thoroughly seasoned; in some cases from 10 to 48 per cent of moisture was taken out of it. The air when heated to about 110° or 120° is sent through the timber at a rate of about 48 miles per hour; the heat being regulated according to the quality of the timber. Honduras mahogany exposed to a heat of 300°, would have the whole of the moisture taken from it in 48 hours. This process, however, sometimes splits the timber. Out of a hundred specimens of wood experimented upon, varying from one inch to twelve inches square, not one of them split: even some openings which were visible before the process was applied, were found to be closer after it. Perhaps 9 inches square is the limit to which the operation can be successfully applied.

1750. Notwithstanding, however, all care in seasoning, when timber is employed in a damp situation it soon decays; and one of the principal remedies against that is good drainage, without which no precautions will avail. It is most important to take care that earth should not lie in contact with the walls of a building for the damp is quickly communicated, in that case, by their means to the ends of timbers, and rot soon follows. No expedient to guard against this contingency is so good as what are called air drains.

1751. When the carcass of a building is complete, it should be left as long as possible to dry, and to allow to the timbers what may be called a second seasoning. The modern practice of finishing buildings in the quickest possible period, has contributed more to dry rot than perhaps any other cause; and for this the architect has been blamed instead of his employer, whose object is generally to realize letting or to enjoy occupation of them as early as possible. After the walls and timbers of a building are once thoroughly dry, all means should be employed to exclude an accession of moisture, and delay is then prejudicial.

1752. Among the many inventions to preserve wood from decay, those of England have proved the most successful. In 1737 a patent was granted to Mr. Emerson to prepare timber with hot oil. This was followed by various recommendations early in the present century; those of later date consist of:—I. Kyan's process, 1832, who steeped the timber in a solution of *bichloride of mercury*, known as corrosive sublimate (*par.* 1742.) It appears to penetrate fir less than some other woods (Faraday). The wood thus treated becomes of less specific gravity, less flexibility, and more brittle. II. Sir William Burnett's patent of 1836, was for using the chloride of zinc. III. M. Bréant in 1837 suggested sulphate of iron, which was found not to alter the qualities of the timber as did the corrosive sublimate. IV. Margary's patent, 1837, is for steeping timber in a solution made of one pound of sulphate of copper with eight gallons of water. Wood impregnated with sulphate of copper (blue vitriol) will not last longer in sea water than any other wood. But wood so treated will last longer in the soil than if either tarred or charred. Its application for the prevention of rot is beneficial, and it might be used where not exposed to the action of water, on account of the solubility of the salts. The proportion of the sulphate should be one pound to four gallons of water; we have also met with the proportion of one pound to two gallons; perhaps the strongest is the best (*par.* 1752*b*.) V. Payne, 1841, patented a system for using two solutions; first, sulphate of iron, which would form an oxide of iron in the cells; and secondly, carbonate of soda: some very good results were obtained, but the process must be done under pressure and with the greatest care.

1752*a*. VI. Bethell's patent, 1838, consists in the injection of oil of tar, containing creasote and a crude solution of acetate of iron, commonly called pyrolignite of iron, after the air in the wood has been extracted. This process is effective to a great extent, and full particulars are given by G. R. Burnell in his paper read before the Society of Arts 1860, from which we have been quoting. It, however, can only be recommended for railways and other large works; the offensive smell and increased danger by fire should deter its use in house building. In the best creasoting works, the oil is injected at a temperature of 120° and under a pressure of 150 lbs. on the square inch, so that ordinary fir timber absorbs 10 lbs. weight of the creasote per cubic foot; the wood should be weighed to ascertain that it did absorb that quantity. For all engineering purposes, fir timber thus treated is far more durable than the best oak, teak, or other hard woods, and the cost of the operation is very small. Timber which has just been taken out of water contains so large a quantity that it resists the entrance of the oil; unless time, therefore, be given for it to be first dried, it would necessarily be badly prepared.

1752*b*. VII. Dorsett and Blythe, 1863, patented the injection of heated solutions of sulphate of copper (*par.* 1752, IV.), a process said to have been adopted by French, Spanish, Italian, and other railway companies. Amongst its advantages, they state that wood so prepared is rendered to a great extent incombustible; and that for out-door purposes it has a clean yellowish surface, without odour, requires no painting, remaining unchanged for any length of time. Experience of the English processes shows that creasoting is the most generally successful; the application of the sulphate of copper is satisfactory in many cases; while the other processes, although no doubt of occasional value, have been practically abandoned. They all depend for their success upon the skilful and conscientious manner in which they are applied; for as they involve chemical actions on a large scale, their efficiency must depend upon the observation of the minute practical precautions required to exclude any disturbing causes.

CURE OF DRY ROT.

1753. It is no easy matter to cure the dry rot where it has once taken root. If it be found necessary to substitute new timbers for old ones, every particle of the fungus, known as the *Merulius lacrymans*, must be removed from the neighbourhood of such new timbers. After scraping it from the adjoining walls and timbers, perhaps no better application than one of the washes above mentioned can be employed, inasmuch as they can always be with safety applied to the parts. An extraordinary degree of heat, about 300°, would effect the same purpose, but this, especially in the case of floors, is difficult in application. Coal tar has been found useful, but its extremely unpleasant odour, which always arises at a moderate degree of heat, is an objection to its use in houses of any class. We have also ourselves found that a weak solution of vitriolic acid with water will generally stop the rot if it have not gone too far. Pyroligneous acid is recommended, and, we think, very usefully, as a remedy for preventing the spreading of the disease. The precautions indicated above for the prevention of decay, although not always successful, must be deemed preferable to the application of after remedies.

Sect V

IRON.

1754. Iron is a metal found in almost all parts of the world, and though not mentioned by Homer, and hence, we may suppose, in his time extremely scarce, it is now more abundant than any of the other metals, and is, at the same time, the most useful. Although, with the exception of tin, it is the lightest of all metals; yet it is, when pure, very malleable and extremely hard. Its malleability is increased by heat, whereas most other metals, as they are heated, become more brittle. It is the only known substance whereon the loadstone acts, and its specific gravity to water is as 7632 to 1000.

1755. The iron manufactured in Great Britain is obtained from three species of the ore. The *Lancashire*, which is very heavy, fibrous in texture, and of a dark purple colour inclining to black, and lodged in veins. The *Bog ore*, which has the appearance of a deep yellow clay, and is found in strata of from twelve to twenty inches in thickness. And lastly, *Iron stones*, of an irregular shape, frequently in beds of large extent, similar to other stony masses, and often intersected with seams of pit coal. It is principally from the argillaceous ore or clay iron-stone that iron is extracted in this country.

1756. After raising, the ores are selected and separated as much as possible from heterogeneous substances. They are then roasted in large heaps in the open air, for the purpose as well of freeing them from the arsenic and sulphur they contain as to render them friable or easy of reduction to a powder. The roasting is performed by means of bituminous coal, and the result is a substance full of fissures, friable, and a deprivation of all vitreous lustre. After this it is transferred to the crushing mill for complete pulverization, whence it is carried to the smelting furnace for conversion into iron. Herein it undergoes two separate processes: first, the reduction of the oxide to a metallic state; second, the separation of the earthy particles in the form of scoria. These operations are conducted by submitting the ore, ordinarily mixed with certain fluxes, to the action of carbon at a very high temperature, in what are called blast furnaces, which vary in height from twelve to sixty feet, and are of the form of truncated cones, sometimes however of pyramids, terminating usually in cylindrical chimneys, whose internal diameter is from four to six feet. The interior of these furnaces is usually of a cylindrical form, whose internal diameter is from four to six feet. Their cavity is usually of a circular form, except at the *crucible* or *hearth*, where it becomes a right rectangular prism, oblong in a direction perpendicular to the blast orifices or *tuyeres* of the bellows. The sides of the crucible are most commonly formed of gritstone. The *boshes*, which are in the form of an inverted quadrangular pyramid approaching a prismatic shape, are placed above the crucible, and above them rises the conical body of the furnace, which is lined with fire-bricks, and, in ascending, is contracted similarly to the narrow end of an egg, until it terminates in the chimney. The furnace is of course constructed in the most solid manner, and strengthened by iron bands and bars. The bellows employed are mostly of a cylindrical form, and their pistons worked either by water or steam. The blast holes, which are in the upper part of the crucible, and frequently placed on opposite sides, but so that the two opposite currents may not impinge upon one another, are two in number. Openings are provided at the lower part of the crucible for the discharge of the metal and scoria, and are kept stopped by clay and sand upon the exterior when the furnace is in operation. The reduction is commenced by gradually heating up the furnace until capable of being entirely filled with fuel, and then, as its contents begin to sink, alternate changes of ore, mingled with *flux*, and of charcoal and coke, are added. The blast is now let on, and the metal in the ore, parting with its oxygen, flows by degrees, subsiding to the bottom of the crucible, covered with a melted *slag*, which is occasionally let off by removing the clay from one or more, if necessary, apertures in the crucible; and on the bottom of the furnace becoming filled with the metal, which generally occurs after nine to twelve hours, the iron itself is discharged by one of these openings into a fosse of sand mixed with clay. When the iron has flowed out the aperture is again closed, and by this method the furnace is kept in constant action.

1757. Limestone of the best quality is employed as a flux to assist the fusion of the ore, which it accomplishes by vitrefying the earths wherewith it is mixed up with the oxide of iron. The iron when run out from the blast furnace in the state of cast iron is far from being in a pure state, having a coarse grain, and being brittle. In its conversion to bar iron, it undergoes one of the two following processes, as charcoal or coke may be employed. In the former case a furnace much resembling a smith's hearth is used, having a sloping cavity sunk from ten to twelve inches below the blast pipe. After the cavity has been filled with charcoal and scoria, a pig of cast iron, well covered with hot fuel, is placed opposite the blast pipe. The blast being introduced, the pig of iron lying in the very hottest part soon begins to melt, and runs down into the cavity below, where, being out of the influence of the blast, it becomes solid, and is replaced in its former position, and the

cavity is again filled with charcoal. It is there again fused, and so on a third time, all these processes being accomplished in three or four hours. The iron, thus again solid, is taken out, and very slightly hammered, to free it from the attached scoria; after this it is returned to the furnace, in a corner whereof it is stacked, out of the action of the blast, and well covered with charcoal, where it remains gradually to cool until sufficiently compact to bear the *tilt* or *trip hammer* (to be *shingled*, to force out the cinders), which is moved by machinery, and whose weight is from 600 to 1200 lbs. Thus it is beaten till the scoriæ are forced out. and the particles of iron welded together, when it is divided into several portions, which by repeated heating and hammering are drawn into bars, in which state it is ready for sale.

1758. There are various methods of procuring the blast; the first, and most ancient, is by means of bellows; the latest, which has been found in the mining districts to be a contrivance of great importance, is the placing a series of vanes attached to an axis, which, by machinery, are made to revolve in a box with great rapidity. A pipe passing from the outside of the box to the furnace conveys the air to it as the vanes revolve, a new portion continually entering by a hole at the axis. The air thus driven through at its natural temperature constitutes a *cold blast* in contradistinction to air heated by artificial means or *hot blast*. This latter system was discovered by J. B. Neilson, of Glasgow, about the year 1826; his patent expired in 1842. At the present day air is forced into the furnaces at a temperature of 600°, and even of 800° Fahr., although at the commencement it was rarely used above 300°. The irons obtained from the former process are considered to be tougher and stronger than those obtained from the latter process, and present a closer texture and a smaller crystallization than the latter irons. The Blaenavon, Coed Talon, Lowmoor, and Muirkirk irons are amongst the most esteemed varieties. Perhaps it may be laid down as a general principle that where pig-iron is remelted with coke in the cupola furnace, for the purposes of the ironfounder, or refined with coke in the conversion of forge pig into bar iron, it is of little consequence whether the reduction of the ore has been effected with the *hot* or the *cold* blast; but where large castings have to be run directly from the smelting furnace, the quality of the metal will, no doubt, suffer from the use of the hot blast.

1759. The proportion of pig or cast iron from a given quantity of ore varies as the difference in the metallic contents of different parcels of ore and other circumstances, but the quantity of bar obtained from pig iron is not valued at more than 20 per cent.

1760. The other process for manufacturing bar iron, which is that chiefly employed in this country, is conducted in reverberatory furnaces, usually called *puddling furnaces*. The operation begins with the fusion of the cast iron in refinery furnaces, like the one above described. When the iron is fully melted, a tap-hole is opened in the crucible, and the metal and slag flow out together into a fosse covered with clay well mixed with water, by which a coating is formed that prevents the metal from sticking to the ground. The finer metal forms a slab about ten feet long, three feet broad, and from two to two and a half inches in thickness. For the purpose of slightly oxidizing it, and to make it brittle, it is much sprinkled over with cold water. In this part of the process it loses in weight from 12 to 17 per cent. After this, it is broken up into pieces, and placed on the hearth of a reverberatory furnace, in portions heaped up to its sides in piles which rise nearly to the roof, leaving a space open in the middle to give room for puddling the metal as it flows down in streams. When the heat of the furnace has brought it to a pasty state, the temperature is reduced, a little water being sometimes thrown on the melted mass. The semi-liquid metal is stirred up by the workman with his *puddle*, during which it swells, and parts with a large quantity of oxide of iron, which burns with a blue flame, so that the mass appears ignited. As it refines, the metal becomes less fusible, or, as the workmen say, it begins to *dry*. The puddling goes on until the whole charge assumes the form of an incoherent sand, when the temperature is gradually increased to give it a red white heat, at which period the particles begin to agglutinate, and the charge, in technical language, *works heavy*. The refining is now considered finished, and the metal has only to be formed into balls, and condensed under the rolling cylinder. From this state it is brought into *mill bar iron*. After this last operation, several pieces are welded together, from which it acquires ductility, uniformity, and cohesion. A lateral welding of four pieces together now follows, and the mass passes through a series of cylinders as in the first case, and becomes English bar-iron.

1761. The lamination of iron into sheets is by a refinery furnace, with a charcoal instead of a coke fire.

1762. Malleable iron is often obtained from the ores directly, by one fusion, if the metallic oxide be not too much mixed with foreign substances. It is a mode of working much more economical than that above described, and from the circumstance of its having been long known and used in Catalonia, it is known by the name of the *method of the Catalonian forge*. The furnace employed is similar to the refiner's forge already described. The crucible is a kind of semicircular or oblong basin, eighteen inches in diameter, and

eight or ten in depth, excavated in an area, or small elevation of masonry, eight or ten feet long, by five or six broad, and covered in with a chimney. The tuyere is placed five or six inches above the basin, inclining a little downwards, and the blast is received from a water blowing machine. The first step consists in expelling the water combined with the oxide, as well as the sulphur and arsenic when these are present. This, as usual, is done by roasting in the open air, after which it is reduced to a tolerably fine powder, and thrown at intervals by shovels-full upon the charcoal fire of the forge hearth, the sides and bottom of the basin being previously lined with *brasques* (coats of pounded charcoal). It gradually softens and unites into lumps more or less coherent, which finally melt and accumulate in the bottom of the crucible or basin. A thin slag is occasionally let off from the upper surface of the melted metal in the basin through holes which can be closed and opened at the discretion of the workman. The melted iron preserves a pasty condition owing to the heat communicated from above. When a mass sufficiently great has accumulated, it is removed, put under the hammer, and forged at once. A lump, or bloom, of malleable iron is thus produced in the space of three or four hours. Four workmen are employed at one forge, and by being relieved every six hours, they are enabled to make 86 cwt. of iron per week. In the Catalonian forge, 100 lbs. of iron are obtained from 300 lbs. of ore (a mixture of sparry iron, or carbonate and hematite), and 310 lbs. of charcoal, being a produce of 33 per cent.

1763. A visit to some of the iron districts is necessary fully to understand the processes we have above shortly described; but the founding of iron may be well enough observed in the metropolis, though not on so large a scale as in some of the provinces. A succinct description, however, is given under the heading FOUNDRY, Chap. III. Sec. xi.

1764. We here subjoin a summary of the modern observations on iron (collected from various authorities) as given in Rankine's *Civil Engineering*. The metallic products of the iron manufacture are of three kinds: I. MALLEABLE OR WROUGHT IRON; II. CAST IRON; and III. STEEL: both the latter being certain compounds of iron with carbon. Some investigators affirm that nitrogen is one of the essential constituents of steel, but this requires confirmation. The strength and other good qualities of these products depend mainly on the absence of impurities, and especially of certain substances which are known to cause brittleness and weakness, of which the most important are sulphur, phosphorus, silicon, calcium, and magnesium. Sulphur, and (according to Mushet) calcium, and probably also magnesium, make iron what is termed *red short*, that is, brittle at high temperatures. Phosphorus and (according to Mushet) silicon make it *cold short*, that is, brittle at high temperatures. These are both serious imperfections, but the latter is the worst defect.

1764*a*. WROUGHT OR MALLEABLE IRON in its perfect condition is pure, or nearly pure, iron; its strength is in general greater or less according to the greater or less purity of the ore and fuel employed in its manufacture. Malleable iron is distinguished by the property of *welding*. Two pieces, if raised nearly to a white heat and pressed or hammered firmly together, adhering so as to form one piece. It is essential that the surfaces to be welded should be perfectly clean and free from oxide of iron, cinder, and all foreign matter. Where several bars are to be faggoted or rolled into one, they require careful *piling*, so as to ensure the pressure exerted by the hammer or the rollers being transmitted through the whole mass; otherwise the finished bar or piece may show flaws marking the divisions between the bars of the pile. Wrought iron, although it is at first made more compact and strong by *reheating* and hammering, or otherwise working it, soon reaches a maximum strength, after which all reheating and working rapidly makes it weaker. Good *bar iron* has in general attained its maximum strength, and therefore, in all operations of forging it, the desired size and figure ought to be given to it with the least possible amount of reheating and working. In large forgings, the tenacity is only about *three fourths* of that of the bars from which the forgings were made, and sometimes even less.

1764*b*. It is still a matter of dispute to what extent and under what circumstances wrought iron loses its *fibrous* structure and toughness, and becomes *crystalline* and brittle. By some authorities it is asserted that all shocks and vibrations tend to produce that change; others maintain that only sharp shocks and vibrations do so; and others that no such change takes place; but that the same piece of iron which shows a *fibrous* fracture, if *gradually broken* by a steady load, will show a *crystalline* fracture, if *suddenly broken* by a *sharp* blow. It is certain, at all events, that iron, whether cast or wrought, ought to be as little as possible exposed to sharp blows and rattling vibrations. Kirkaldy, *Wrought Iron and Steel*, 1863, p. 52, and in his concluding observations (p. 92), states further, that "the appearance of iron may be changed from fibrous to crystalline by merely altering the shape of the specimen so as to render it more liable to snap," and that "iron is less liable to snap the more it is worked and rolled. In the fibrous fractures the threads are drawn out, and are viewed externally, whilst in the crystalline fractures the threads are snapped across in clusters, and are viewed externally or sectionally. In the latter cases

the fracture of the specimen is always at right angles to the length; in the former it is more or less irregular."

1764c. The *continuity of the fibres* near the surface should be as little interrupted as possible. For example, projections formed out of a block by turning, rolling, and hammering, were broken off by blows with a 6 lb. hammer, with the first, fifth, and eighth blows respectively (Rankine, *Proceedings of Inst. of Civil Engineers*, 1843). In iron work which is to sustain shocks and vibrations abrupt variations of dimensions and angular figures must be avoided as much as possible, especially those with reentering angles; for at those points fractures are apt to commence. If two parts of a beam are to be of different thicknesses, they should be connected by means of curved surfaces.

1764d. The fibres of wrought iron are always an indication of its strength, but in the application of such iron we are to be cautious. If the iron be impure in its elements, or has been badly worked, it may be very fibrous and also strong, but in exposing it to a welding heat it loses all its fibre, and is converted into brittle *granulated iron*. This happens frequently with puddled iron and sometimes with charcoal iron. It follows, therefore, that iron which does not retain its fibre after receiving a welding heat is not to be trusted. Only good charcoal iron should be used where strength is required, in case any smithing is to be done to the iron before it is put to use. Where iron is exposed to heat, the very purest and best kinds only should be used: with constant heat, even of low temperature, wrought iron, if not very pure, becomes *granulated*. Very fibrous puddled iron may carry 80,000 lbs. per inch square, when newly made, but it may in a short time be converted into granular iron, and reduced to 20,000 lbs., and be inferior in strength to cast iron. Where this change in the iron would be detrimental to the work steel should be substituted, as its strength is not impaired by any degree of heat beyond a red heat.

1764e. The quality of iron for boiler plates must be attended to from the first stages of its manufacture from the ore, which should be of good quality: even then it may be spoiled in the furnaces. Above all things, states Overman, (whom we are now quoting), hot blast ought to be excluded in these cases; it ought to be a criminal offence to employ hot blast iron for boiler plates. Iron may be fibrous, and when cold very tenacious; but the test consists in heating it red hot and cooling it in cold water. If it continues tenacious it may be considered good; if not it is bad, and unfit for boiler plate.

1764f. Strength and toughness in *bar iron* are indicated by a fine, close, and uniform fibrous structure, free from all appearance of crystallization, with a clear bluish grey colour, and a silky lustre on a torn surface where the fibres are shown. *Plate iron* of the best kind consists of alternate layers of fibres crossing each other, and ought to be nearly of the same tenacity in all directions. The breaking strain and contraction of area of puddled *steel plates*, as in iron plates, are greater in the direction in which they are rolled; whereas in cast steel they are less. (Kirkaldy.)

1765. CAST IRON is the product of the process of smelting iron ores. The total quantity of carbon in *pig iron* ranges from 2 to 5 per cent. of its weight. Different kinds of pig iron are produced from the same ore in the same furnace, under different circumstances as to temperature and quantity of fuel. A high temperature and a large quantity of fuel produce *grey* cast iron, which is further distinguished into Nos. 1, 2, and 3, and so on; No. 1 being that produced at the highest temperature. A low temperature and a deficiency of fuel produce *white* cast iron. *Grey* cast iron is of different shades of bluish grey in colour, granular in texture, softer and more easily fusible than *white* cast iron, which latter is silvery white, either granular or crystalline, comparatively difficult to melt, brittle, and excessively hard. It appears that the differences between these kinds of irons depend on the proportions of carbon in them. Thus *grey* cast iron contains 1 per cent., and sometimes less, of carbon in chemical combination with the iron, and from 1 to 3 or 4 per cent. of carbon in the state of plumbago in mechanical mixture; while *white* cast iron is a homogeneous chemical compound of iron with from 2 to 4 per cent. of carbon. Of the different kinds of *grey* cast iron, No. 1 contains the greatest proportion of plumbago (which renders iron comparatively weak and pliable), No. 2 the next, and so on.

1765a. There are two kinds of *white* cast iron, the granular and the crystalline. The granular sort can be converted into *grey* cast iron by fusion and slow cooling. *Grey* cast iron can be converted into granular *white* cast iron by fusion and sudden cooling. This takes place most readily in the best iron. Crystalline *white* cast iron is harder and more brittle than granular, and is not capable of conversion into *grey* cast iron by fusion and slow cooling. It is said to contain more carbon than granular *white* cast iron; but the exact difference in their chemical composition is not yet known. *Grey* cast iron No. 1 is the most easily fusible, and produces the finest and most accurate castings; but it is deficient in hardness and strength.

1765b. The order of strength of cast iron among different kinds from the same ore and fuel is as follows:—Granular *white* cast iron, *grey* cast iron No. 3, No. 2, and No. 1. Crystalline *white* cast iron is not introduced into this classification, because its extreme brittleness makes it unfit for use in engineering structures. Granular *white* cast iron also,

although stronger and harder than *grey* cast iron, is too brittle to be a safe material for the entire mass of any girder, or other large piece of a structure. It is used to form a hard and impenetrable *skin* to a piece of *grey* cast iron by the process called *chilling*. This consists in lining the portion of the mould where a hardened surface is required with suitably shaped pieces of iron. The melted metal, on being run in, is cooled and solidified suddenly where it touches the cold iron; and for a certain depth from the chilled surface, varying from about $\frac{1}{8}$ to $\frac{1}{2}$ inch in different kinds of iron, it takes the *white* granular condition, while the remainder of the casting takes the *grey* condition. Even in castings which are not chilled by an iron lining to the mould, the outermost layer, being cooled more rapidly than the interior, approaches more nearly to the *white* condition, and forms a skin harder and stronger than the rest of the casting. The best kinds of cast iron for large structures are No. 2 and No. 3; because being stronger than No. 1, and softer and more flexible than *white* cast iron, they combine strength and pliability in the manner which is best suited for safely bearing loads that are in motion. A strong kind of cast iron called *toughened cast iron*, is produced by the process, invented by Morries Stirling, of adding to the cast iron, and melting amongst it, from one-fourth to one-seventh of its weight of wrought iron scrap.

1766. Soft grey cast iron is the best sort; it yields easily to the file when the external crust is removed, and is slightly malleable in a cold state. It is, however, more subject to rust than the white cast iron, which sort is also less soluble in acids. Grey cast iron has a granulated fracture with some metallic lustre. White cast iron in a recent fracture has a white and radiated appearance, indicating a crystalline structure.

1767. The most certain test of the goodness of a piece of cast iron is by striking the edge with a hammer, which if it make a slight impression, denoting some degree of malleability, the iron is of a good quality, provided it be uniform; if fragments fly off, and no sensible indentation be made, the iron will be hard and brittle. The difference between good and bad iron is shown mainly by the breaking; good iron breaks like a piece of good fir timber; bad iron will break like a carrot, it snaps in two. Cast iron, when at a certain degree of heat, may be cut like a piece of wood with a common saw. This discovery was announced in a letter from M. Dunford, director of the iron works of Montalaire, to M. d'Arcet, and published in the *Annales de Chimie*. The experiment was tried in 1813 by a gentleman of the Philosophical Society at Glasgow, who with the greatest ease cut a bar of cast iron, previously heated to a cherry red, with a common carpenter's saw, in the course of less than two minutes. The saw was not in the least injured by the operation.

1768. The security afforded by iron for supporting weight, and against fire, has, of late years, very much increased the use of it, and may in many cases entirely supersede the employment of timber. Again, it is valuable from its being not liable to sudden decay, nor soon destroyed by wear and tear, and, above all, from its plasticity.

1769. Steel, the hardest of the metals and the strongest of known substances, is a compound of iron with from 0·5 to 1·5 per cent. of its weight of carbon. These, according to most authorities, as noticed by Rankine, are the only essential constituents of steel. Impurities of different kinds affect steel injuriously in the same way with iron. A very small part of its weight, $\frac{1}{2000}$th, of silicon, causes steel to cool and solidify without bubbling or agitation; a larger proportion would make the steel brittle. Manganese improves the steel by increasing its toughness, and making it easier to weld and forge.

1769*a*. The term *steely iron*, or *semi steel*, may be applied to compounds of iron with less than 0·5 per cent. of carbon. They are intermediate in hardness and other properties between steel and malleable iron. In general, such compounds are the harder and the stronger, and also the more easily fusible, the more carbon they contain; those sorts which contain less carbon, though weaker, are more easily welded and forged, and from their greater pliability are the fitter for structures that are exposed to shocks.

1769*b*. Steel is distinguished by the property of *tempering*, that is to say, it can be hardened by sudden cooling from a high temperature, and softened by gradual cooling; and its degree of hardness or softness can be regulated with precision by suitably fixing that temperature. The elevation of temperature previous to the *annealing* or gradual cooling is produced by plunging steel into a bath of a fusible metallic alloy, ranging from 430° to 560° Fahr.

1770. *Steel* is made by various processes which have of late become very numerous. They may all be classed under two heads, viz., *adding* carbon to malleable iron, used in making steel for cutting tools and other fine purposes; the other, *abstracting* carbon from cast iron, used for making great masses of *steel* and *steely iron* rapidly and at a moderate expense. Among the processes are the following:—

1771. I. *Blister steel* is made by *cementation*, by embedding bars of the purest wrought iron in a layer of charcoal and subjecting them for several days to a high temperature. Each bar absorbs carbon, and its surface becomes converted into steel. *Cementation* may also be performed by exposing the surface of the iron to a current of carburetted hydrogen gas at a

high temperature. *Cementation* is also applied to the surfaces of articles of malleable iron in order to give them a skin or coating of steel, and is called *casehardening*.

1772. II. *Shear steel* is made by breaking bars of blister steel into lengths, faggoting them, and rolling them out at a welding heat; repeating the process until a near approach to uniformity of composition and texture has been obtained. It is used for tools and cutting implements.

1773. III. *Cast steel* is made by melting bars of blister steel with a small additional quantity of carbon (in the form of coal tar), and some manganese. It is the purest, most uniform, and strongest, steel, and is used for the finest cutting implements. Another process requiring a higher temperature, is to melt bars of the purest malleable iron with manganese and with the whole quantity of carbon required in order to form steel. The quality as to hardness is regulated by the proportion of carbon. A sort of *semi steel* or *steely iron*, made by this process and containing a small proportion of carbon only, is known as *homogeneous metal*.

1774. IV. *Steel made by the air blast* is produced from molten pig iron by Bessemer's process, wherein the molten pig iron, having been run into a suitable vessel or *converter*, has jets of air blown into it through tubes as the liquid is poured in. The oxygen of the air combines with the silicon and the carbon of the pig iron, and in so doing produces enough of heat to keep the iron in a melted state till it is brought to the malleable condition; it is then run into large ingots, which are hammered and rolled in the usual way. About two hours suffice to convert cold iron into pure steel.

1775. V. *Puddled steel* is made by puddling pig iron, and stopping the process at the instant when the proper quantity of carbon remains. The bloom is shingled and rolled like bar iron. VI. *Granulated steel*, the invention of Capt. Uchatius, is made by running melted pig iron into a cistern of water over a wheel, which dashes it about so that it is found at the bottom of the cistern in the form of grains or lumps of about the size of a hazel nut. These are imbedded in pulverized hæmatite or sparry iron ore, and exposed to a heat sufficient to cause part of the oxygen of the ore to combine with, and extract, the carbon from the superficial layer of each of the lumps of iron, each of which is reduced to the condition of malleable iron at the surface, while its heart continues in a state of cast iron. A small additional quantity of malleable iron is produced by the reduction of the ore. These ingredients being melted together produce steel.

1776. Kirkaldy observes that "Steel invariably presents, when fractured slowly, a silky fibrous appearance. When fractured suddenly, the appearance is invariably granular; in which case also the fracture is always at right angles to the length. When the fracture is fibrous, the angle diverges always more or less from 90°. The granular appearance presented by steel suddenly fractured is nearly free of lustre, and unlike the brilliant crystalline appearance of iron suddenly fractured; the two combined in the same specimen are shown in iron bolts partly converted into steel. Steel which previously broke with a silky fibrous appearance is changed into granular by being hardened. Steel is reduced in strength by being hardened in water, while the strength is vastly increased by being hardened in oil. The increase of strength is greater the higher steel is heated (not being burned) and so treated."

1777. "In a highly converted or hard steel the increase in strength and in hardness is greater than in a less converted or soft steel. Steel plates hardened in oil and joined together with rivets are fully equal in strength to an unjointed soft plate; or the loss of strength by riveting is more than counterbalanced by the increase in strength by hardening in oil. The most highly converted steel does not, as some may suppose, possess the greatest density. In cast steel, the density is much greater than in puddled steel, which is even less than in some of the superior descriptions of wrought iron."

1778. This subject may, perhaps, be considered of greater importance to the architect and engineer, if those experienced scientific men be right, who predict that the time is not far hence when there will be no such metals as either wrought or cast iron; steel taking the place of both for all practical purposes. As one instance among many, it has been urged that the absolute strength of any cast iron girder may be doubled by the judicious use of a very few pounds of steel, costing but a trifle.

Corrosion and Preservation of Iron.

1779. Cast iron will often last for a long time without rusting, if the skin be not injured, which is coated with a film of the silicate of the protoxide of iron, produced by the action of the sand of the mould on the iron. Chilled surfaces of castings are without this protection, and therefore rust more rapidly. The corrosion of iron is more rapid when partly wet and partly dry, than when wholly immersed in water or wholly exposed to the air. It is accelerated by impurities in water, and especially by the presence of decomposing organic matter, or of free acids. It is also accelerated by the contact of the iron with any metal which is electro-negative relatively to the iron, or in other words, has less affinity for oxygen, or with the rust of iron itself. If two portions of a mass of iron are in different

conditions, so that one has less affinity for oxygen than the other, the contact of the former makes the latter oxidate more rapidly. In general, hard and crystalline iron is less oxidable than ductile and fibrous iron. Cast iron and steel decompose rapidly in warm or impure sea water. The purest and the most malleable irons are the most easily attacked by sea water, *when used alone*; for it is to be observed that the fine grained, crystalline, white and brittle metal, which usually resists the action of air and water most successfully, is also the most easily attacked by the dilute acids present in the woods so often used in connection with iron in ship building, or in timber structures in sea water. The most extreme care, and the greatest practical skill, are therefore required in the selection of the irons to be used in certain positions. To R. Mallet we are indebted for a valuable communication to the Institute of Civil Engineers in May 1840, *On the Corrosion of Cast and Wrought Iron in Water*, under protected and unprotected states: an abstract is given in the *Civil Engineer Journal*, iii. p. 424, from the Proceedings of the Institute.

1779*a*. In the Reports of the British Association, 1843 and 1849, Mallet, *On Corrosion of Iron*, further states that iron kept constantly in a state of vibration oxidates less rapidly than that which is at rest. Thus the rails of a railway on which a constant traffic runs, do not rust so quickly as those on which there may be no traffic.

1779*b*. Spencer, *Iron, its active and inactive states*, read before the Liverpool Polytechnic Society, stated that "It required a mixture of air and water, or what is usually termed dampness, to produce rust on iron—one without the other would not do it. Steel filings became rusty in water, because they absorbed the oxygen in the water; if a second quantity of filings be put in, they would not rust, as there was no more oxygen. A coating of carbon effectually prevents iron from oxidation, and it can protect it from a body so strong as even aqua-fortis itself. If the aqua-fortis be diluted with water, the protective power no longer exists. The slightest scratch or abrasion on the surface of the metal also prevented the action of the protecting influence. A piece of solid carbon also imparts a protective property to iron, little short of that given to it by platinum."

1779*c*. Sugar exercises a material influence on iron and other metals: *Athenæum*, Sept. 1853 and May 1854.

1779*d*. The iron wire suspension bridges of France, which have fallen within the last few years, appear to have done so principally through the oxidation of the wires in the portion passing into the anchoring wells: this was notoriously the case with the bridge at Angers. The constant state of humidity prevailing in these wells must sooner or later have rusted the wires, and although the precaution, recommended by Vicat, of surrounding the cables with rich lime had been adopted, the vibration of the bridge had detached the cables from their supposed protecting case, and the spaces between the wires allowed moisture from the exterior to permeate the interior of the cable; at Angers the cables were thus almost entirely rusted through. In such places it is better to employ bar chains.

1780. The following recommendations have been made for preserving iron. I. Boiling the iron in coal tar, especially if the pieces have first been heated to the temperature of melting lead. II. Heating the pieces to the temperature of melting lead and smearing their surfaces whilst hot with cold linseed oil, which dries and forms a varnish. This is recommended by Smeaton; and is a good preparation for painting upon.

1780*a*. III. Painting with white lead in oil, which must be renewed from time to time. Mr. John Braithwaite has stated that his father had used red lead for fifty years with good result; white lead was of no use, as the acid used in the preparation of it produced swelling effects. He had placed rods in a well 200 feet deep, forty-five years since, having painted them with pure red lead, and on taking them up in 1863 he found that their weight was precisely the same. Red lead and one-third litharge made into paint with nut oil will last longer than when mixed with linseed oil. Iron heated and covered with mineral bitumen or asphaltum in the solid state had resisted a moist atmosphere for fifteen years; the natural asphaltum was the best, the liquid asphalte not answering so well; with all other materials the rust had penetrated beneath. C. H. Smith, in a communication to the *Builder*, 1864, p. 318, brought forward the advantages of lime whiting as a preservative of iron from rust. In support of the use of lime, he notices that polished steel goods may be preserved by beating a little powdered lime upon them; and that bricklayers always smear their bright trowels even with damp mortar when leaving work.

1780*b*. IV. Coating with a metal, commonly called *galvanizing*. Zinc is efficient, provided it is not exposed to the acids capable of dissolving it; but it is destroyed by sulphuric acid in the air of places where much coal is burnt; and by muriatic acid in the neighbourhood of the sea. All attempts to use galvanized iron for roofs in large towns or smoky districts have failed. The use of this material will be noticed in the section on Zinc. Tinned iron does not now answer so well even as good zinc. It is known that during the medieval period, iron nail-heads, anchors, dogs, and such like articles were tinned over, no doubt to prevent oxidation; and tinned iron is greatly used for the covering of houses in America. In St. Petersburg and in Moscow, iron is mostly used, but it requires painting. The coppering of iron has failed unless it was done in so expensive a manner as

not to be practicable in any extended employment of it. A coating of lead, or of lead and antimony, is wanted to iron, so as to combine the stiffness and cheapness of iron with the durability of lead. Messrs. Morewood have recently introduced metal plates covered with a uniform coating of lead. These plates are supposed to possess all the advantages of sheet lead, and they can be rendered serviceable at a considerably reduced cost (Hunt, *Handbook*, 1862). Enamelled iron is a late invention, and one tending to be very serviceable.

SECT. VI.

LEAD.

1781. Lead, the heaviest of the metals except gold and quicksilver, is found in most parts of the world. It is of a bluish white when first broken, is less ductile, elastic, and sonorous than any of the other metals: its specific gravity is from 11,300 to 11,479, and a cubic foot, therefore, weighs about 710 lbs. It is soluble in all acids and alkaline solutions, fusible before ignition, and easily calcined. The ore, which is easily reduced to the metallic state by fusion with charcoal, is found mineralised with sulphur, with a slight mixture of silver and antimony, in diaphanous prismatical crystals, generally hexagonal, white, yellowish, or greenish, in Somersetshire, about the Mendip Hills. About Bristol, and in Cumberland, it takes the form of a white, grey, or yellowish spar, without the least metallic appearance: in some places it is in a state of white powder or native ceruse; and in Monmouthshire it has been found native, or in a metallic state.

1782. Exposure to air and water does not produce much alteration in lead, though it quickly tarnishes and acquires a white rust, by which the internal parts are defended from corrosion. Pure water, however, does not alter it; hence the white crust on the inside of lead pipes through which water flows must probably be owing to some saline particles in the water. Lead will form an union with most other metals: one exception, however, is iron. Next to tin, it is the most fusible of metals. It is run from the furnace into moulds; the main form is called a *sow*, the smaller ones *pigs*: from these it is run into sheets, pipes, &c.

1783. Sheet lead is of two sorts, *cast* and *milled*. The thicker sort of the former, or the common cast sheet lead, is manufactured by casting it on a long table formerly made of wood but now of cast iron, (with a rising edge all round it) from 16 to 20 feet in length, and 6 feet in width, which is covered with fine pressed sand beaten and smoothed down with a strike and smoother's plane. The pig lead is melted in a large vessel, near this table, and is ladled into a pan of the shape of a concave triangular prism, whose length is equal to the width of a sheet, from which pan it is poured on to the table or mould. Between the surface of the sand and the *strike*, which rides upon the edges of the table, a space is left which determines the thickness of the sheet. The strike bears away the superfluous liquid lead before it has time to cool, as it moves by hand along the edges of the table before mentioned. When lead is required to be cast thin, a linen cloth is stretched on an appropriate table over a woollen one; in which case the heat of the lead, before spreading it on the cloth, must be less than will fire paper, or the cloth would be burnt. The strike must for the purpose be passed over it with considerable rapidity.

1784. In manufacturing milled lead, it is usual first to cast it into sheets from 8 to 10 feet long according to circumstances, but the width is regulated by the length of the rollers through which it is to be passed in milling; the thickness varies from 2 to 5 inches. By a mechanical action it is made to pass through rollers whose distance from each other is gradually lessened until the sheet is reduced to the required thickness. For a long time a great prejudice prevailed against milled sheet lead; but it is now generally considered that, for the prevention of leakage, milled is far superior to cast lead, wherein *pin holes*, which have naturally formed themselves in the casting, often induce the most serious consequences. The sheets rolled out are about 30 feet long and 6 feet 6 inches in width. The lead from the mines of Walter Beaumont, M.P., in Northumberland, when manufactured for the market is known as "W.B. lead," and is considered the best in quality. Lead melts at a temperature of about 612° to 630° Fahr. The tenacity of sheet lead is 3,300 lbs; and the modulus of elasticity 720,000 lbs.

1785. In *distilled* water which has been freed and kept from the contact of the air, lead undergoes no change; but if the lead be exposed to air and water, it is oxidized and converted into a carbonate with considerable rapidity. This carbonate has the appearance of shining brilliant scales. The presence of saline matter in the water very much retards the oxidation of the lead. So small a quantity as a 30,000th part of the phosphate of soda or iodide of potassium in distilled water, prevents lead from being much corroded, the small deposit which is formed preventing the further corrosion of the metal.

1785*a*. The danger of using water from leaden pipes or cisterns was known even to the Romans. The rarity of any fatal results shows that the risk has been much overrated. This is sufficiently explained by the protecting power of the insoluble salts of lead, formed by the action of the ingredients of the water on the lead, hindering the subsequent supplies of

water from coming in contact with the metal. Distilled waters and waters which are remarkably *pure* dissolve lead, and become impregnated with it. The more *impure* the water such as Thames water, the more it will form a protecting incrustation. A new cistern should be allowed to form this coating, by the water standing in it for some time without being renewed. To expedite the action a little phosphate of soda, or iodide of potassium, or a few drops of sulphuric acid may be added. The lid or cover of cisterns should not be of lead, as the vapour condensing in it possesses all the solvent power of distilled water. Water which has flowed over leaden roofs, more particularly in towns, carries with it from the surface some soluble salt. The holes with which lead is often riddled are caused by the larva of an insect, the *Callidium bajulus*, in the stomach of which lead is often found (Kirby and Spence, *Entomology*, i. p. 235). A pipe conveying water impregnated with sulphur salts, has after a time been coated with a sulphate or sulphide, and this sulphide being perfectly insoluble in pure water, and equally so in water not too excessively charged with foreign matters to be potable, renders the leaden vehicle perfectly harmless. Dr. Schwarz, a chemist of Breslau, has stated that by passing a hot solution of sulphide of potassium through leaden pipes, the face is transmuted from the metallic state to that of a sulphide in a few minutes, at a cost too insignificant to mention. It is said that water in the mines of galena, the sulphide of lead, can be drank with impunity.

1786. *Wetterstedt's patent marine metal* for roofing and other purposes is the invention of a native of Germany, introduced into England in 1837 by Messrs. Young, Dowson, and Co., and manufactured by Messrs. Johnson, both of Limehouse. It is composed of lead and antimony, and is adapted to all purposes to which lead is usually put. Its advantages are its malleability, its great tenacity, elasticity and durability, and resistance to acids, oxidation, and the action of the sun and atmosphere. It does not lose in weight. It is manufactured in sheets:—I. 9 feet by 3 feet, at 3 lbs. and 2 lbs. per square foot; II. 8 feet by 2 feet 9 inches at 1½ lbs. and 1 lb. per square foot; and III. 8 feet by 2 feet 6 inches, at 8 ounces per square foot. No. I. sizes are employed for flats, large roofs, covering to stairs, and small sloping and curb roofs. No. II. sizes for verandahs. No. III. for lining damp walls; it should be fixed with wrought copper nails. The roof of the Royal Polytechnic Institution was covered with this patent metal in 1838; it is still in a perfect condition. In price it is somewhat under that of lead per cwt., but a much less weight per foot superficial than of that material is used. The *patent metallic canvas*, is a combination of Wetterstedt's patent metal No. III., with canvas of various substances and strength, as calico, japanned cloth, woollen, &c., varying according to the purposes to which it is to be applied. By this combination, sufficient strength is given to a metal weighing only eight ounces per foot to enable it to be used as a perfectly waterproof and secure covering. When used to damp walls, the calico is placed outside, forming a good surface for papering, painting, &c. The cement with which the combination is effected is stated to be elastic and impervious to damp, and a thorough disinfectant.

Sect. VII.

COPPER.

1787. Copper, among the first of the metals employed by the early nations of the world, is neither scarce nor difficult to work and extract from its ore. When pure it is of a pale red colour; a cubic foot of cast copper will weigh 537 lbs., in sheet 549 lbs., and when hammered 556 lbs.; the weight of a bar 1 foot long and 1 inch square varies from 3·63 lbs. to 3·81 lbs.; all the weights depending upon the copper being more or less hammered. Its elasticity and hardness are very considerable, and it is so malleable that it may be hammered into fine leaves. It is also very tenacious, a wire of a tenth of an inch in diameter being capable of sustaining 360 lbs. The tenacity of cast copper is 19,000; in sheet, 30,000; in bolts, 36,000; and in wire, 60,000. The modulus of elasticity or resistance to stretching, being 17,000,000. The transverse elasticity or resistance to distortion is 6,200,000 lbs. Copper is diminished to about two-thirds by a temperature of 600° Fahr.

1788. The sixteen copper smelting works at Swansea and Neath are supplied with ore from Cornwall, Devonshire, Ireland, and from some foreign and colonial sources. There are six smelting establishments at Liverpool and St. Helens, which obtain their ore from the Cumberland mines, from Alderley Edge, and such ores as arrive at the port of Liverpool. The single works at Cheadle produce a very fine copper, which is used in the manufacture of brass wire; the ore is selected carefully from different mines somewhat widely scattered. The Mona smelting works obtain the ores from the Mona and Pary's mines in Anglesea and from those in North Wales. The "once famous" mines in Pary's mountain formerly yielded the yellow sulphuretted ore of copper, to an annual amount of from 40,000 to 80,000 tons. This ore usually contains from one and a half to twenty-

five per cent. of copper, and is partly dug in what are called *packages*, and partly blasted by gunpowder, and then broken into small pieces previous to its being roasted. This operation is performed in kilns, whose shape has a resemblance to lime-kilns, in which expedients are used for removing the ore as it is roasted, and adding fresh ore. The kilns are arched level with the upper surface of the ore, and adjoining and communicating with the kiln is the floor of a condensing chamber to receive the sulphureous vapours generated in the kiln, which fall down in the form of the finest flowers of sulphur. Several hundred tons at one time are put into the kiln, and for completing the operation six months are required. The ore is reduced to one fourth of its previous quantity by roasting, and is then washed and pressed to remove the impurities. The richer ores are then dried, and removed for smelting and refining in reverberatory furnaces from which it is at length produced in short bars or pigs. The water which filters through the fissures is often highly impregnated with sulphate of copper, and this water is pumped up into rectangular pits about thirty feet long, twelve broad, and two deep, to mix with that in which the roasted ore has been washed; and in it are immersed pieces of iron, which, combining with the sulphuric acid, precipitate the copper in the form of a red-coloured powder slightly oxidated. The precipitate thus obtained very frequently gives above 50 per cent. of pure copper, and is even more profitable to the worker than the metal produced from the crude ore.

1788*a*. In the process of copper smelting the specimens produced are—I. Calcined ore, or copper ore after the extraction of the sulphur. II. Coarse metal, obtained by the second process of smelting, producing about 40 per cent. of copper. III. Calcined coarse metal, for extracting the sulphur from II. IV. Metal "brych," producing about 65 per cent. of copper. V. Close regule, producing about 70 per cent. VI. Spongy regule, producing about 80 per cent. VII. Blister copper, producing about 95 per cent. VIII. Select ingot, the fine metal as prepared for market. IX. Tough ingot, ready for market. X. Tough cake, hammered out by hand. XI. Tough bar copper, as prepared for the manufacture of wire.

1789. Sheet copper was formerly much used for its lightness to cover roofs and flats; but it is almost superseded now by the use of zinc, which is much cheaper, and nearly if not quite as durable; and which, moreover, is not so liable to be corrugated by the action of the sun. Copper is reduced to sheet by being passed through large rollers, by which it can be rendered very thin. The thickness generally used is from 12 to 18 ounces to the foot superficial. Exposed to the air its lustre is soon gone; it assumes a tarnish of a dull brown colour, gradually deepening by time into one of bronze; and, lastly, it takes a green rust or calx, called *patina* by the antiquaries, which, unlike the rust of iron, does not injure and corrode the internal parts, confining itself to the surface, and rather preserving than destroying the metal. Hence one of the most important applications of copper is in cramps for stone work, especially when they are exposed to the air, when its cost, which is about six or eight times that of iron fastenings, can be afforded. It may be here well to observe, that if water is collected from roofs for culinary purposes, copper must not be used about them, neither should any reservoirs for collecting and holding it be made of that metal, as on the surface is formed a film of verdigris, which is poisonous.

1790. Alloyed with zinc, it forms *brass* for the handles of doors, shutters, locks, drawers, and the furniture generally of joinery. The usual proportion is one part of zinc to three of copper; than which it is more fusible, and is of a fine yellow colour, less liable to tarnish from the action of the air, and so malleable and ductile that it can be beaten into very thin leaves and drawn into very fine wire. The extremes of the proportions of zinc used in it are from 12 to 25 per cent. of the whole. Even with the last, if well manufactured, it is quite malleable, although zinc by itself scarcely yields to the hammer. The appearance of brass is frequently given to other metals by washing them over with a yellow lacquer or varnish.

1791. Copper with *tin* (which last melts at 426° Fahr. and resists oxidation better than any of the more common metals) in the proportion of one tenth to one fifth of the whole forms a composition called bronze or bell-metal, used in the foundery of statues, bells, cannons, &c. When tin forms nearly one third of the alloy, a beautiful white close-grained brittle metal is formed, susceptible of a very high polish, which is used for the specula of reflecting telescopes.

SECT. VIII.

ZINC.

1792. Zinc is found in all quarters of the globe. In Great Britain it is abundant, though therein never found in a native state. It usually contains an admixture of lead and sulphur. When purified from these, it is of a blue light colour, between lead and tin,

inclining to blue. The ore, after being hand-dressed to free it from foreign matter, is first calcined, by which the sulphur of the calamine and the acid of the blende are expelled The product is then washed to separate the lighter matter, and the heavy part which remains, being ground in a mill, is mixed with one eighth of its weight of charcoal, or with one third of its bulk of powdered coal. This mixture is placed in pots, resembling oil jars, to be smelted. A tube passes through the bottom of each, the upper end being terminated by an open mouth near the top of the pot, and the lower end going through the floor of the furnace into water. By the intense heat of a furnace the ore is reduced, the zinc is volatilized, escaping through the tube into the water, wherein it falls in globules, which are afterwards melted and cast into moulds. Thus procured, however, it is not pure, as it almost invariably contains iron, manganese, arsenic, and copper. In order to free it from these, it is again melted and stirred up with sulphur and fat, the former whereof combines with the heterogeneous metals, leaving the zinc nearly pure, and the latter preventing the metal from being oxidated. At the Vieille Montagne Zinc Company's Works, the pots are placed in the furnaces at six o'clock every morning; at six o'clock in the evening the smelting is complete; the metal is then drawn out and run into metal moulds, after which it passes into the rolling house, and is again melted and recast in a metal mould to produce ingots of the proper size and weight for the required gauge of the sheets to be rolled; this second melting is also desirable to obtain proper purity.

1793. Under rollers at a high temperature, zinc may be extended into plates of great tenuity and elasticity, or drawn into wire. These rollers are from 2 feet 8 inches to 6 feet n length, and the original thickness of the plate subjected to them is about 1 inch. A wire, one tenth of an inch diameter, will support 26 pounds. If zinc be hammered at a temperature of 300°, its malleability is much increased, and it becomes capable of much bending. Its fracture is thin, fibrous, and of a grain similar to steel. It can be drawn into wire $\frac{1}{260}$th of an inch in diameter, which is nearly as tenacious as that of silver. The specific gravity is somewhat below 7·0, but hammering increases it to 7·2. When heated, it enters into fusion at a heat of about 680° or 700°: at a higher temperature it evaporates; and if access of air be not permitted, it may be distilled over, by which process it is rendered purer than before, although then not perfectly pure. When heated red hot, with access of air it takes fire, burns with an exceedingly beautiful greenish or bluish flame, and is at the same time converted into the only oxide of zinc with which we are acquainted, consisting of 23·53 parts of oxygen combined with 100 of metal.

1794. Zinc, though subject to oxidize, has this peculiarity, that the oxide does not scale off as that of iron, but forms a permanent coating on the metal, impervious to the action of the atmosphere, and rendering the use of paint wholly unnecessary. Dr. von Petenkoffer, however, has stated that zinc is oxidized to the extent of 130 grains per square foot in twenty-seven years, about two-fifths of the oxide being removed by the moisture of the atmosphere. Its expansion and contraction are greater than those of any other metal: thus, supposing 1·0030 to represent the expansion, 1·0019 is that of copper, and 1·0028 that of lead; but the thicker the zinc, the less its contraction and expansion. The tenacity of zinc is from 7,000 to 8,000. The weight of a cubic foot varies from 424 lbs. to 449 lbs. The tenacity of zinc to lead is as 16·616 to 3·328, and to copper as 16·616 to 22·570; hence a given substance of zinc is equal to five times the same substance in lead, and about three-fourths of copper.

1795. On the first introduction of zinc into this country as a material, the trades with which it was likely to interfere used every exertion to prevent its employment; and, indeed, the workmen who were engaged in laying it, being chiefly tinmen, were incompetent to the task of so covering roofs as to secure them from the effects of the weather. Hence, for a considerable period after its first employment, great reluctance was manifested by architects in its introduction. A demand for it has, however, gradually increased of late, and the comparatively high prices of lead and copper will not entirely account for the disparity of consumption. The Vieille Montagne Zinc Mining Company, about the year 1861, took steps to improve the quality of the zinc for use in this country, the mode of laying zinc roofs, and for the prevention of the use of thin gauges of sheets which are unfit for the purpose. Their zinc possesses a reputation for its purity and excellence. The result of this care, and the better understanding of the merits of the material, has caused it to be now extensively used for purposes which are noticed in the following chapter.

1795*a*. A sheet of pure zinc, as stated by J. Edmeston in his *Report on Zinc*, will be of an even colour, without black spots or blotches; it will be very ductile, bending readily backwards and forwards in the hand; and it will not easily break. If impure, it will be the opposite of all this. If there be any iron in it, it will be worthless; if it contain any lead, it will still, though to a less extent, contain the germs of destruction within itself.

1795*b*. Common zinc is destroyed by the sulphuric acid in the atmosphere where much coal is burned; and by muriatic acid in the neighbourhood of the sea. Cement does not injure zinc; but lime, and calcareous waters destroy it; and zinc pipes to flues over wood fires are destroyed by them.

1796. GALVANIZED IRON is a designation misapplied to that iron which may have received a coating of zinc ; it should be called *zinked iron*. The metal is first cleaned perfectly by the joint action of dilute acid and friction, and then plunged into a bath of melted zinc, covered with sal ammoniac, and stirred until the iron is sufficiently coated with zinc. No galvanic action whatever occurs between the metals ; it is simply a coating. This process, it is stated, was invented in France by Maloin, in 1742, but not patented until 1836 by Sorel. The efficacy of the process depends upon the skill employed in removing every trace of the scales of the hydrous oxide of iron, and in its further treatment. The coating must not become loosened, or any hole be made through it, as moisture obtaining access to the iron will rapidly extend, and the scales of the oxide of iron will force up the slight zinc covering, when the iron will be gradually destroyed, unless it be at once painted. When well executed it may perhaps be durable for a lengthened period, but when badly prepared it is not so valuable as iron well painted (*par.* 1779*b*.). At the Houses of Parliament, where the iron roofing plates were galvanized, it was found necessary from 1860 to commence coating them with paint or some other material.

1796*a*. The other process, which might be properly called *zinked-tinned iron*, is thus performed :—The sheets of iron are pickled, scoured, and cleaned, as for ordinary tinning. A wooden bath is half filled with a solution—the proportion of 2 quarts of muriate of tin with 100 quarts of water. Over the bottom of the bath is spread a thin layer of finely granulated zinc, then a cleaned plate, and so on alternately; the zinc and iron and the fluid constitute a weak galvanic battery, and the tin is deposited from the solution so as to coat the iron, in about two hours, with a dull uniform layer of metal. The iron in this state is then passed through a bath containing fluid zinc covered with sal ammoniac mixed with an earthy matter, to lessen the volatilization of the sal ammoniac, which becomes as fluid as treacle. Two iron rollers are driven by machinery to carry the plates through the fluid at any velocity previously determined ; the plates thus take up a very regular and smooth layer of zinc, which owing to the presence of the tin beneath, assumes its natural crystalline character. This is said to be the process adopted by Messrs. Morewood and Rogers, whose patents date in 1846 and 1850. It is asserted that iron thus prepared does not warp or buckle ; that the plate is not affected by the heat of the zinc, whereas thin sheet iron, kept in molten zinc for a few minutes, becomes so brittle that it will not bear folding or grooving ; that the plate is equally covered with zinc, whereas by the dipping process the lower half receives more than the upper : and that zinc is not contaminated by iron as when dipped, the contamination increasing with each dipping until the zinc in the bath becomes so injured as to be worthless, it being well known that the alloy of zinc and iron is more oxidizable than zinc alone, or than zinc and tin. Professor Brande has stated that in common tinned plate, the combination is such that the oxidization of the iron is accelerated by the tin, so that the iron is the protecting, and the tin the protected, metal, but in this case the reverse effect ensues, the iron is the protected metal, and the zinc the protector.

1796*b*. Time has proved that galvanized iron has corroded after *seven years* in a roof-gutter ; and the state of most of the roofs to railway sheds and stations and such like places, proves that at least some sorts of galvanized iron will decay ; the difficulty always is to ascertain what description of coating the iron has undergone. Galvanized iron bolts do not act upon oak either in sea or in fresh water, when care has been taken not to remove the zinc in driving them.

1796*c*. Galvanized iron is said to be nearly the same cost as zinc, and to be less than one quarter as liable to expansion or contraction : to be equally as durable as lead ; less in first cost, and not to require boarding ; to be not quite one-third the price of copper, and to be equally as durable ; and as compared with plain iron, the cost is increased about two-thirds, but that it increases the strength and durability of the iron.

1797. The soldering used is composed of spirits of salts killed by putting about three ounces of zinc to a pint of spirit ; care must be taken that this solder soaks well between the laps.

SECT. IX.

SLATE.

1798. Slate is a species of argillaceous stone, and is an abundant and most useful mineral. This material is so soft, that the human nail will slightly scratch it, and is of a bright lamellated texture. Its constituent parts are argill, earth, silex, magnesia, lime, and iron ; of the two first and the last in considerable proportion. The building slate is the *schistus tegularis*.

1799. *Mica slate* is a species of gneiss, distinguishable by containing little or no felspar, so that it consists chiefly of quartz and mica. It has a laminated or slaty structure, with the silky lustre of mica; it is a tough material in directions parallel to its layers, but is more perishable than gneiss. In thin layers it may be used for roofing purposes. *Chlorite slate* is also laminated, soft, and easily cut, but more opaque than talc, and is sometimes used for roofing purposes. It has a green or greenish grey colour and silky lustre. *Hornblende slate* is hard, tough, durable, and impervious to water, and is used for flagstones. *Grauwacke slate* is a laminated claystone, containing sand and sometimes fragments of mica and other minerals. It is used for roofing and flag stones. All these descriptions of slate are inferior to the ordinary *clay slate*.

1800. Slate quarries usually lie near the surface; and, independent of the splitting grain, along which they can be cleft exceedingly thin, they are mostly divided into *stacks*, by breakings, cracks, and fissures. Slate is separated from its bed, like other stones, by means of gunpowder, and the mass is then divided into scantlings by wedges, and, if necessary, sawn to its respective sizes by machinery. The blue, green, purple, and darker kinds are most susceptible of thin cleavage, the lighter-coloured slates being coarser. The instruments used in quarrying and splitting slates, are slate knives, axes, bars, and wedges.

1801. The tenacity of slate is from 9,600 to 12,800. The modulus of elasticity varies from 13,000,000 to 16,000,000. The resistance to rupture is 5000. The weight of a cubic foot is from 175 lbs. to 181 lbs. The transverse strength of Welsh slate is greater than any other mineral product of the stone kind. For such qualities as strength, space, and cleanliness, no other material is so cheap as slate.

1802. The slates used about London are brought chiefly from Bangor in Carnarvonshire The slate quarries of North Wales are the most important in this country. The chief works are situated as follows, and belong respectively to the geological formations named:—

Penrhyn, Bangor } Cambrian.
Llanberis, Dinorwic }
Ffestiniog, Port Madoc: Lower Silurian.
Llangollen, Llangollen: Upper Silurian.
Machynlleth, Aberdovey, Lower Silurian.
Royal Slate, Bangor: Cambrian.

The large quarries at Penrhyn near Bangor, belonging to Colonel Pennant, and from which the best Bangor slates are obtained, are worked in successive terraces; the slate is obtained in immense masses by blasting, therefore the waste is enormous, but being got rid of without difficulty, the price is kept moderate. These quarries have been variously estimated as yielding from 30,000*l.* to 40,000*l.* worth of slates per annum. Many smaller ones have lately been opened near Bangor, all supplying "best Bangor" slates, without affecting the produce of the well-established works at that place. The Llangollen quarries are remarkable for the size of the slates they can obtain.

1803. The Delabole quarries in Cornwall have been worked for a considerable period; these slates are shipped from Tintagel and Boscastle. This grey-blue slate, confined till lately to the western counties, is now obtained in London; the Wellington College at Sandhurst, Berkshire, is roofed with them. The Tavistock slates from Devonshire were at one period in considerable demand. One of the most esteemed slates is of a pale blue-green, brought from Kendal in Westmoreland, and called Westmoreland slate. There are quarries in the neighbourhood of Ulverstone, in Lancashire; and the Cumberland sea-green slate works are at Maryport.

1804. The extended use of this material for paving, shelving, cisterns, &c., has caused numerous companies to be formed for the working of old, and of many new, quarries, chiefly in North and South Wales. Amongst the companies putting forth peculiarities of slate, are the Dorothea West, Green, Blue, and Red, Slate Company, situate in Carnarvonshire, which supplied the pale green slates for the Charing Cross Railway Hotel, the London Bridge Hotel, and the Star and Garter Hotel at Richmond. The Llanfair Green and Blue Slate Company is also to be noticed.

1805. The slates of Scotland are not in much repute. The Balahulish quarries in the north of Scotland are very extensive, as between five and seven millions of roofing slates are quarried annually. The weight of this number would be about 10,000 tons, and the quantity of rubbish being generally five or six times as much as the slates, some 50,000 or 60,000 tons of refuse have to be disposed of, which in this case are thrown directly into the sea, securing an immense saving of expense.

1806. The more important slate quarries in Ireland are in the southern division of the country, viz., Killaloe, county Tipperary; Valentia, county Kerry; Benduff, near Glandore Harbour, county Cork; and near Ashford Bridge, county Wicklow. The chief one is at Curraghbally, situate about six miles from Killaloe. The colour of the slates is a dull bluish grey, preferred by many to the decided blue of the Bangor quarries; they are greatly used in the west of Ireland, where they have superseded the Welsh slates. The colour of the Valentia slates is rather greener than those above mentioned. They are generally thicker and more uneven on the surface, and so are better suited for the exposed

aspects of buildings in the western counties. This quarry has more capabilities for sawn flags and slabs, of which a large amount is now exported to England for cisterns, baths, urinals, &c. The Banduff quarry is nearly given up. The slates from Ashford Bridge both in colour and quality closely resemble the Bangor slates. (Wilkinson, *Geology, &c. of Ireland*, 1845.)

1807. A fine sound texture is the most desirable among the properties of a slate; for the expense of slating being greatly increased by the boarding whereon it is placed, if the slate absorbs and retains much moisture, the boarding will soon become rotten. But a good slate is very durable. Its goodness may readily be judged by striking it as a piece of pottery is struck; a sonorous, clear bell-like sound is a sign of excellence; but many pieces of the slate should be tried before a conclusion can be arrived at. It is thought to be a good sign, if, in hewing, it shatters before the edge of the *zax*. The colour, also, is some guide, the light blue sort imbibing and retaining moisture in a far less degree than the deep black-blue sort. The feel of a slate is some indication of its goodness: a good one has a hard and rough feel, whilst an open absorbent slate feels smooth and greasy. The best method, however, of testing the quality of slates is by the use of water, in two ways. The first is, to set the pieces to be tried edgewise in a tub of water, the water reaching above half way up the height of the pieces: if they draw water, and become wet to the top in six or eight hours' time, they are spongy and bad; and as the water reaches less up them, so are the pieces better. The other method is, to weigh the pieces of slate, and note their weights. Let them then remain for twelve hours in water, and take them out, wiping them dry. Those that on re-weighing are much heavier than they were previous to their immersion should be rejected. Where the character of a slate quarry is not previously known, experiments of these sorts should never be omitted.

1808. The following comparison of the advantages of slates over tiles is given by R. atson, former Bishop of Llandaff. That sort of slate, other circumstances being the same, s esteemed the best which imbibes the least water; for water not only increases the weight of the covering, but in frosty weather, being converted into ice, swells and shivers the slate. This effect of frost is very sensible in tiled houses, but is scarcely felt in those which are slated, for good slates imbibe but little water; though tiles, when well glazed, are rendered in some measure similar to slate in this respect. The bishop took a piece of Westmoreland slate and a piece of common tile and weighed each of them carefully. The surface of each was about thirty square inches. Both the pieces were immersed in water about ten minutes, then taken out and weighed as soon as they had ceased to drip. The tile had imbibed about a seventh part of its weight of water, and the slate had not imbibed a *two-hundredth* part of its weight; indeed, the wetting of the slate was merely superficial. He placed both the wet pieces before the fire; in a quarter of an hour the slate was perfectly dry, and of the same weight as before it was put into the water; but the tile had lost only about twelve grains it had imbibed, which was, as near as could be expected, the very same quantity that had been spread over its surface; for it was the quantity which had been imbibed by the slate, the surface of which was equal to that of the tile. The tile was left to dry in a room heated to sixty degrees, and it did not lose all the water it had imbibed in less than six days.

1809. Professor Ansted states that the best slates are those which are most crystalline, and which, when breathed upon, give out a faint argillaceous odour; when this was given out strongly, then the slates would readily decompose.

1810. The largest slab of slate, perhaps, ever as yet obtained, was the one sent by the Llangollen Slate Company to the International Exhibition of 1862. It was 20 feet long, 10 feet wide, and weighed 4½ tons; the thickness, however, was not named. The Welsh Slate Company, whose quarries are at Festiniog, in Merionethshire, sent several slabs averaging 14 feet by 7 or 8 feet. All the slate from this neighbourhood possesses the remarkable quality of splitting with great facility, and with wonderful accuracy of surface, into thin laminæ or sheets. Some of these thinly divided sheets are obtained 5 to 10 feet long from 6 to 12 inches wide, and not more than the sixteenth of an inch in thickness. They are so elastic as to bend like a veneer of wood. (Hunt, *Handbook*, 1862.)

SECT. X.

BRICK AND TILE.

1811. A brick is a factitious sort of stone, manufactured from argillaceous or clayey earth, well tempered and squeezed into a mould. When so formed, bricks are stacked to dry in the sun, and finally burnt to a proper degree of hardness in a clamp or kiln. The use of bricks is of the highest antiquity. They are frequently mentioned in the historical

books of the Old Testament; but whether they were merely sun-dried or burnt in a kiln seems uncertain. We are inclined to doubt the burning of them at a very remote period. It will immediately occur to the reader that the making of bricks was one of the tasks imposed upon the Israelites during their servitude in Egypt. Though the oldest remains in Egypt are of stone, Pococke describes a pyramid of unburnt bricks, which are composed of a black sandy earth, intermixed with pebbles and shells, the sediment deposited by the overflowing of the Nile. This species of bricks is still common in Egypt and many other parts of the East. By the ancient Greeks and Romans, both burnt and unburnt bricks were used; the method of making the latter whereof is thus described by Vitruvius, in the third chapter of his second book: "I shall first," says that author, "treat of bricks, and the earth of which they ought to be made. Gravelly, pebbly, and sandy clay are unfit for that purpose; for if made of either of these sorts of earth, they are not only too ponderous, but walls built of them, when exposed to the rain, moulder away, and are soon decomposed; and the straw, also, with which they are mixed, will not sufficiently bind the earth together, because of its rough quality. They should be made of earth, of a red or white chalky, or a strong sandy nature. These sorts of earth are ductile and cohesive, and not being heavy, bricks made of them are more easily handled in carrying up the work. The proper seasons for brick-making are the spring and autumn, because they then dry more equably. Those made in the summer solstice are defective, because the heat of the sun soon imparts to their external surfaces an appearance of sufficient dryness, whilst the internal parts of them are in a very different state; hence, when thoroughly dry, they shrink and break those parts which first dried; and thus broken, their strength is gone. Those are best which have been made at least two years; for in a period less than that, they will not dry thoroughly. When plastering is laid and set hard on bricks which are not perfectly dry, the bricks, which will naturally shrink, and consequently occupy a less space than the plastering, will thus leave the latter to stand of itself. From its being extremely thin, and not capable of supporting itself, it soon breaks to pieces; and in its failure, involves sometimes even that of the wall. It is not, therefore, without reason that the inhabitants of Utica allow no bricks to be used in their buildings which are not at least five years old, and also approved by a magistrate.

1812. "There are three sorts of bricks: the first is that which the Greeks call *Didoron* (διδῶρον), being the sort we use; that is one foot long and half a foot wide. The other two sorts are used in Grecian buildings; one is called *Pentadoron*, the other *Tetradoron*. By the word *doron*, the Greeks mean a palm, because the word δῶρον signifies a gift which can be borne in the palm of the hand. That sort, therefore, which is five palms each is called Pentadoron; that of four palms, Tetradoron. The former of these two sorts is used in public buildings, the latter in private ones. Each sort has half bricks made to suit it, so that when a wall is executed, the course on one of the faces of the wall shows all of whole bricks, the other face of half bricks; and being worked to the line on each bed the bricks on each bed bond alternately over the course below." Vitruvius concludes the chapter with the mention of the bricks made at Calentum in Spain, at Marseilles in France, and Pitane in Asia, which are specifically lighter than water.

1813. It is to be regretted that plastering with cement, a practice which is more to the interest of the brickmaker and bricklayer than to the consumer, has become so prevalent in this country. These tradesmen thus get rid of their worst bricks, which are hidden by a coat of plaster; the building soon decaying when the heart of the wall is bad. Colour seems to be the objectionable quality about this material, the commonplace architect forgetting that form is much more essential to beauty than colour. In the times of Jones and Wren, red brick was beautifully wrought into architectural forms, of which a few examples still remain in the metropolis: and by Palladio, bricks were occasionally used for columns without smearing them over with plaster.

1814. In England, the best earth for making bricks is a clayey loam, neither abounding with too much sand, which renders them brittle, nor with too large a portion of argillaceous matter, which causes them to shrink and crack in drying. It should be dug at the least a year before it is wrought, that by exposure to the atmosphere it may part with all extraneous matter which it possessed when first dug. The general practice is, however, to dig it in the autumn, and allow it to remain through the winter to mellow and pulverize, by which the operation of tempering is greatly facilitated. Upon this operation the quality of the brick mainly depends, and great attention should be bestowed upon performing this part of the process in a proper manner. This branch of the manufacture was formerly executed by throwing the clay into shallow pits, and subjecting it to be trodden by men and oxen; a method which has been advantageously superseded by a clay or pug-mill, with a horse track.

1815. As soon as the clay has been thoroughly tempered by one of the methods above named, it is taken to the moulder's bench, where it is cut by the moulder's assistant, generally a woman or a lad, into pieces rather larger than the mould, which are passed on to the moulder, who throws it with some force into the mould, which has been previously

dipped in sand. He presses it down, so that it may fill the whole of the cavity, striking off the superfluous clay with a flat wooden rule. The newly-formed brick is then turned out of the mould on to a thin board, somewhat larger than a brick, and it is removed by a boy to a latticed wheelbarrow, and conveyed, covered with fine dry sand, to the *hack*. A handy moulder, working fifteen hours, will mould 5000 bricks. In the hacks, which are eight courses in height, the bricks are arranged diagonally above each other, with a passage between each for the circulation of air round them. The time required for drying in the hacks will of course depend on the fineness of the weather; it is but a few days if the season be propitious; and they are then turned and reset wider apart, after which, in about six or eight days, they are ready for the clamp or kiln. If the weather be rainy, the bricks in the hack must be covered with wheat or rye straw; and as they ought to be thoroughly dry before removing to the clamp or kiln, a few are generally selected from different parts, and broken, to ascertain if the operation of drying has been well performed. The moisture arising from bricks when burning is very injurious to their soundness.

1816. The quantity of clay necessary to make 1000 bricks will be somewhere about 54 cube feet, which allows about 5 feet for shrinkage in drying and burning; for $1000 \times 8\frac{1}{2}$ in. $\times 2\frac{1}{2}$ in. $\times 4$ in. $= 49\ 2\ 3''\ 4'''$. The cost of making 1000 bricks, in the neighbourhood of London, is nearly as follows:—

Digging, wheeling, carting, &c.	0	1	6
Moulding, stacking, &c.	0	11	6
Sand, one-sixth of 2*s.*	0	0	4
Straw for hacks	0	0	9
Barrows, moulds, planks, &c.	0	0	6
Fuel 9 cwt. per 1000	0	10	6
	= £1	5	1

1817. In the brickfields about London, bricks are mostly burnt in what are called *clamps*. These are generally oblong in form, and their foundations are made with the driest of the bricks from the hacks, or with common worthless bricks, called place bricks. The bricks for burning are then arranged, tier over tier, to the height assigned to the clamp, according to the quantity to be burnt, and a layer of breeze or cinders, two or three inches deep, is placed between each course of bricks, and the whole, when built up, covered with a thick stratum of breeze. On the western face of the clamp a vertical fireplace is formed, about 3 feet in height, from which flues are driven out by arching the bricks over, so as to leave a space about one brick wide. The flues run in a straight direction through the clamp, and are filled with a mixture of coals, breeze, and wood, closely pressed together. If the bricks are required to be burnt quickly, the flues should not be more than 6 feet apart; but if time do not press, the flues need not be nearer than 9 feet to each other, and the clamp is allowed to burn slowly. It is possible, if required, to burn a clamp in a period of from 20 to 30 days, according to the dryness of the weather. The practice of steeping bricks in water after they have been burnt, and then again burning them, has been found to have the effect of considerably improving their quality.

1818. A new mode of burning bricks in clamps has been patented by Robert White at Erith, wherein the advantages are stated to be that, 1st, nearly all the bricks are burnt into stocks, and the yield of inferior bricks is reduced from 35 to about 10 per cent. of the total make; and, 2ndly, the bricks are so much improved in colour and soundness as to give them a considerable additional value in the market over common stocks.

1819. The *kilns* which are used for burning bricks are usually 13 feet long, by 10 feet 6 inches in width, and 12 feet in height. The walls are one brick and a half thick, and incline inwards as they rise. A kiln is generally built to contain 20,000 bricks at each burning. The fireplace consists of three arches, which have holes at top for distributing heat to the bricks. These are placed on a lattice-like floor, and first undergo a gentle action of the fire for two or three days, in order to dry them thoroughly. As soon as they thus become ready for burning, the mouth of the fireplace is dammed up with what is called a *shinlog* (which consists of pieces of brick piled against each other, and closed with wet brick earth), leaving about it sufficient room to introduce a faggot. The kiln is then supplied with brushwood, furze, heath, faggots, &c., and the fire is kindled and kept up until the arches assume a white appearance, and flames appear through the top of the kiln. The fire is then slackened, and the kiln gradually cooled. This process of alternately raising and slacking the heat of the kiln is repeated till the bricks are thoroughly burnt, which is usually accomplished in about eight and forty hours.

1820. The malm or marl stock, which is of a bright yellowish uniform colour and texture, is not always to be had, especially in the London districts; in consequence of which, several years ago, it was discovered that chalk mixed in certain portions with loam, and treated in the usual manner, proved an excellent substitute for it. It not only was found to improve the colour, but to impart soundness to the brick; and the practice is now generally adopted about London. At Emsworth in Hampshire, and also at Southampton,

ooze, or sludge, from the sea-shore, containing much saline matter, is used for a similar purpose: these bricks, however, have not the rich brimstone colour of the London malm stock, nor the regular stone-coloured hue of the Ipswich or Suffolk bricks.

1821. The finest marl stocks, which are technically called *firsts*, or *cutters*, are principally used for arches of doorways and windows, quoins, &c., for which purposes they are rubbed and cut to their proper dimensions and form. There is also a red cutting brick, whose texture is similar to the malm cutter, which must not be confounded with the red stock. The next best, which are chiefly used for principal fronts, are called *seconds*; they are not quite so uniform in colour, nor so bright as the last, but are, nevertheless, a handsome and durable brick.

1822. *Stocks* are red and grey, both sorts being equal in texture. The red sort are burnt in kilns. The grey stocks are less uniform in their colour than seconds, and are of rather an inferior quality. They are used for common fronts, and walls.

1823. *Place bricks*, or *peckings*, sometimes also called *sandel*, or *samel bricks*, are those which, having been outermost or furthest from the fire in the clamp, or kiln, have not received sufficient heat to burn them thoroughly. They are consequently soft, uneven in texture, and of a red colour. These should never be used in a building where durability is required. The name was formerly applied to the second quality of bricks, and these are still so called in Ireland, being used for inside walls: the Irish harder burnt brick, having a semi-glazed surface, is called *fire brick*, and is used for exterior work where expense is not an object; of course it lasts much longer than the other sorts.

1824. *Burrs* and *clinkers* are such bricks as have been violently burnt, or masses of several bricks run together in the clamp or kiln.

1825. The red bricks derive their colour from the nature of the soil whereof they are composed, which is generally very pure. The best of them are used for cutting-bricks, and are called red rubbers. In old buildings they are frequently found set in lime putty, and often carved into ornaments over arches, windows, doorways, &c.

1826. *Firebricks*, so called from their capability of resisting the most violent action of the fire, are of a dark red colour, and of very close texture; they are made about 9 inches long, 4½ inches broad, and 1½ inches thick. The loam of which they are made is yellow, harsh to the touch, and contains a considerable portion of sand. Their quality renders them highly serviceable in furnaces and ovens. The greatest part of those used about London were formerly brought from Hedgerly, a village near Windsor, whence they obtained the name of Windsor bricks. This sort of brick is made also in various parts of Wales, whence they are called *Welsh lumps*; also at Newcastle; at Poole in Dorsetshire; at the Hurlford works near Glasgow; and at Stourbridge; the latter supplies chiefly the London market, but the material is one of the dearest. Fire clay, and flue linings for furnaces, are extensively used. The Dinas brick, manufactured by the Ynisymudu Company, near Swansea, stands a heat that will melt the Stourbridge brick.

1827. *Paving bricks* are for the purpose which their name implies, and their dimensions are the same as those of the foregoing sort.

1828. *Dutch clinkers* and *Flemish bricks* vary little in quality; they are exceedingly hard, and are used for the paving of stables, yards, &c., though they are by some objected to, as being too hot for the horses' feet. The former are 6 inches long, 3 inches broad, and 1 inch thick, and are often laid on edge in various fanciful forms, as the herring-bone, &c.

1829. *Compass bricks* are circular on the plan, and are chiefly employed for *steyning*, or walling round wells.

1830. *Concave* or *hollow bricks* are made like common bricks, but hollowed on one side in the direction of their length, and are adapted to the construction of drains and water-courses. Other *hollow* bricks are noticed in *par.* 1831*c*.

1831. Amongst the many qualities and varieties of bricks now in use in the metropolis, the following may be enumerated in addition to those already mentioned. The *Cowley, Essex and Kent bricks*. From Cowley are sent stocks, best yellow, and white cutters; yellow and white seconds, paviours, pickings, &c. The *Aylesford and Burham* works, near Maidstone, on the river Medway, formerly the property of the late Thomas Cubitt, produce *gault* bricks of good quality. (See *par.* 1831*f*.)

1831*a*. The *Suffolk bricks*, called white Suffolks, are of two or more qualities, expressly made for facings, and are expensive; the *best* are rarely to be obtained in London, being sold in the locality of their manufacture. They have a disagreeable cold hue, rendered still more dull after a few years' wear in the smoky atmosphere even of a provincial town. They are not so well burnt as those which are somewhat of a light pink or salmon tint. These latter are to be bought at the kiln at about 17*s*. per thousand, and by some persons are thought to make better brickwork than those which fetch 60*s*. or more per thousand in London. The works supply superior white and red (kiln burnt) *Suffolk* facings, splays, door-jambs, coping bricks, stable clinkers, &c.; dark red facings, rubbers, splays, paving bricks, &c.; bright yellow malm facings, and cutters of best quality. Mean quality, and pale malm seconds, pickings, paviours, &c. A dark-coloured brick from *Huntingdon* is

of a finer colour, uniform, much smoother than ordinary, and equal to those made in Kent.

1831*b*. *South Staffordshire* supplies a blue vitrified sewerage and paving brick (as used on Charing-cross suspension bridge, 1856, and on Chelsea new bridge), and a channeled stable brick. It is stated that the *Tipton blue brick*, when used for facings, lets in the wet most thoroughly, either through the brick or through the mortar joints, so that walls of this material should be built hollow. The construction of the work was questioned, as 9 and 14 inch walls have been erected with these bricks with success: as they are scarcely absorbent, mortar does not thoroughly adhere to them; this want of adhesion might be remedied by well soaking the bricks before using them.

1831*c*. *Hollow* and *pierced bricks* of several shapes and sizes are supplied by various manufacturers. A *beaded brick*, drilled with holes, for garden walls, to avoid the necessity of nailing in training trees, are made at Stony Stratford, in Northamptonshire.

1831*d*. *Black bricks* are obtained from Cowbridge in South Wales; these were used at All Saints' Church, Margaret Street, and cost £4 per thousand. The Ballingdon or Ewell deep black rubbing and building bricks, probably so rendered by manganese, are soft in make, and dead-looking in colour. The same factory, and Chalfont, supply dark, and bright, red rubbers; with black headers, glazed and unglazed. Red and black bricks are sent from Burgess Hill, Sussex; and from Maidenhead, in Berkshire.

1831*e*. *White glazed bricks* are useful for cleanliness, and for obtaining reflected light. Best white, and buff, silica pressed facing bricks, are also to be obtained.

1831*f*. *Beart's patent bricks* are made at Arsley near Hitchin, on the Great Northern Railway, of the following qualities, ranged according to price:—White rubbers; hand made moulded solid brick, equal to the best Suffolks; No. 1 best selected white facing brick (pierced); and ordinary; these two are of uniform colour, hard and well burnt, and used extensively for facings; No. 2 mingled, red and pink, vary from the above only in colour, and are equal in every respect to the best made stock bricks. These bricks are made from the *Gault* clay, one of the subcretaceous formations interposed between the chalk and the wealden deposits, or between the chalk and the upper oolite. The composition varies, for although it is of a tolerably uniform dark blue colour, it sometimes contains large quantities (comparatively) of the hydrous oxide of iron; and in others it contains much of the bicarbonate of lime, in combination. The former burn in the kiln into a deep red brick or tile of rather inferior quality; the latter are used for the pierced hard white bricks above described. It is stated that these bricks are required to be burnt with great care, for if the calcination of the lime should take place under such conditions as to leave the lime in a caustic state, it will slack on exposure to the weather, or when moisture is applied to it. There is some difference of opinion as to whether mortar can be made to adhere to the smooth hard face of these bricks to make sound and strong work.

1832. By the 17th Geo. III. cap. 42. all bricks made for sale were directed, when burnt, to be not less than $8\frac{1}{2}$ inches long, $2\frac{1}{2}$ inches thick, and 4 inches wide. This statute, which was enacted for the purpose of levying a duty, is now no longer in force, and the manufacturer is at liberty to make bricks and tiles of whatever size and form may be best suited to the work for which they are used. This act having been rescinded, has led to the introduction of *moulded* and *ornamented* bricks to a vast extent, which will probably be still further extended as brickmaking machines become more useful and certain in their operations. The patents for them are now very numerous: some of them are stated to make up to 20,000 per day, as may be required. The size of the brick, however, has been retained, and habit will, no doubt, continue it in favour, especially for repairs.

1832*a*. Bricks laid in the summer season should be well saturated with water previous to laying; and if the work be left for a day only, the walls should be as carefully covered up as in the winter, for in hot weather the mortar sets too rapidly, and hence the necessary cohesion is destroyed; an evil much aggravated by the dust constantly hanging about the bricks, more especially at that season of the year.

1833. A valuable paper, *On the transverse strength of bricks*, was delivered by Mr. W. Hawkes at the Institute of British Architects, January 1861. He stated that he had always tested bricks by their transverse power in preference to the crushing weight which was but seldom called in question, as it tells nothing if the bricks will resist from 30 to 100 tons dead weight. It would often be useful to know if in a 9 inch wall we could distribute a weight, say of 13 tons, over an opening 90 inches wide, having only 40 inches depth; supposing that the bricks be of moderate strength and the mortar be as strong as the bricks. The pressure and weights were applied in each case in the centre of the brick.

1833*a*. He experimented on *Dutch clinkers* (made at Moor, near Gouda, in South Holland, from the slime deposited on the banks of the river Yssel; and formerly from that of Haarlem Meer; the clay or slime is washed to get rid of the earthy matter before being moulded; the colour is lightish yellow brown); Tipton blue bricks; Birmingham, hand and machine made; Leeds, ditto; Bridgewater; Colchester; Oxford; and London, &c.; with *tiles* of various kinds. As, however, these experiments were made to a calculated standard size of 7 inches long, 4·5 inches wide, and 3 inches thick, the results are

not generally useful for a work of this description. But we give the few actual weights borne by certain bricks. Thus the 9 Leicester bricks carried at the ordinary size 1,462 lbs., 1,392 lbs., 1,252 lbs., 1,132 lbs., 1,052 lbs., 1,002 lbs., 902 lbs., and 892 lbs. The 9 from Rugby carried 1,222 lbs., 1,022 lbs., 1,012 lbs., 862 lbs., 822 lbs., 552 lbs., 422 lbs., and 362 lbs. The 7 London bricks carried 1,142 lbs., 1,042 lbs., 952 lbs., 662 lbs., 652 lbs., 422 lbs., all being *stocks*; the last, a *place* brick, carried 270 lbs. The 7 London bricks (second set) carried 970 lbs., 690 lbs., 580 lbs., 400 lbs., all *stocks*; and 650 lbs., 490 lbs., 340 lbs., all *place*; the *frog* was not allowed for in the calculation.

1833*b*. The following are the ascertained weights of bricks of the sizes stated:—

	ins.	ins.	ins.	lbs.	cwts. per 1000.
London stocks	$8\frac{3}{4}$	$\times 4\frac{1}{4}$	$\times 2\frac{3}{4}$	= 6·81	= $60\frac{3}{4}$
Red kiln	$8\frac{3}{4}$	$\times 4\frac{1}{4}$	$\times 2\frac{3}{4}$	= 7·00	= 63
Welsh fire	9	$\times 4\frac{1}{2}$	$\times 2\frac{3}{4}$	= 7·84	= 65 to 75
Paving	9	$\times 4\frac{1}{2}$	$\times 1\frac{3}{4}$	= 5·00	= 45
Dutch clinkers	$6\frac{1}{4}$	$\times 3$	$\times 1\frac{1}{2}$	= 1·55	= 14
Irish fire	$8\frac{3}{4}$	$\times 4\frac{1}{8}$	$\times 2\frac{5}{8}$		= 67
Worcestershire, solid, machine made				8·75	
Ditto, perforated				6·00	
Staffordshire, solid, hand made				9·50	
London stock, hand made				5·75	

1833*c*. Brickwork expands with great heat. Mr. Hawkes's experiments, already noticed on a furnace chimney, 54 feet 7 inches in height, showed that the result of six trials was an elongation of 1·425 inches. The great heat of the furnace chimney for melting iron is never reached in house flues, but since the introduction of hot air cockles and hot water furnaces, particularly the high-pressure, the heat of these flues is increased fivefold compared with flues from open fireplaces. An iron bar might perhaps be heated to redness in some of the furnace flues. In another chimney, at Thames Bank, in a height of 80 feet, the brickwork showed an expansion at times of $\frac{5}{8}$ of an inch.

1834. Tiles, which in their constituent parts partake much of the nature of bricks, are plates of clay baked in a kiln, and used instead of slates, or other covering of the roofs of houses. The clay whereof tiles are formed will always make good bricks, though the converse does not hold, from the toughness required on account of their being so much thinner than bricks. The common kinds are made of a blue clay, found in many parts about London, and mostly deeper seated than brick earth. The best season for digging it is in September and October, and it should then lie exposed during the winter. It may, however, be turned up in January, and worked in February; and, as in brick, so in tile-making, the more care bestowed on beating and tempering the clay, the better will be the tiles. Tiles are burnt in a kiln constructed on the same principles as the brick-kiln, but with the addition of a cone, having an opening at top round the chamber of the kiln. They require much care in burning. If the fire be too slack, they will not burn sufficiently hard; and if too violent, they glaze, and suffer in form.

1835. *Plain* or *crown tiles* are such as have a rectangular form and plane surface. They were made $10\frac{1}{2}$ inches long, $6\frac{1}{4}$ inches broad, and $\frac{5}{8}$ of an inch thick, by the statute. They are manufactured with two holes in them, through which, by means of oak pins, they hang upon the laths. In using all coverings of this species, one tile laps over another, or is placed over the upper part of the one immediately below; that part of the tile which then appears uncovered is called the *gauge* of the tiling. *Terro-metallic* tiles for roofs, with two projections at the back to catch on the laths in lieu of pegs, are now in use. *Italian tiles*, which were made about 1840, by Brown of Surbiton, differ somewhat from their first prototype, as instead of being flat, they are slightly curved, fit easily one into the other, with a horizontal indentation across the upper part, to prevent the wind drifting the rain over the tile head; they have either wide or narrow vertical rolls. Such tiles are usefully employed in picturesque buildings in the country. Taylor's *new roofing tiles* have a plane surface and a slight turned up edge at the sides, a lump on the surface near the upper edge prevents the upper tile slipping; a cover tile is of a similar size and form; these tiles have been lately used, as at the new railway station in Liverpool Street. They are recommended as being half the weight of ordinary plain tiling, each tile weighing under 4 lbs; and as light as slating; they may be laid to as flat a pitch as slates; and that 180 will cover a square of roofing.

1836. *Ridge roof* and *hip tiles* are formed cylindrically, to cover the ridges of houses. They should be 13 inches long, and girt about 16 inches on the outside. Weight about 5 lbs. Ridge tiles, plain, and with cresting, are now introduced in red, blue, black, and green ware. Plain, flanged, rolled top, and ornamental groved ridging tiles, are commonly seen.

1837. *Gutter tiles* are about the same weight and dimensions as ridge tiles, though differing in form, and are for the valleys of a roof. They are now rarely used, their place having been supplied by lead, and lately by zinc in common work.

1838. *Pan* or *Flemish tiles* have a rectangular outline, with a surface both convex and concave, thus . They have no holes for pins, as plain tiles have, but are hung on to the laths by a knot of their own earth on their underside, nearest the ridge, formed when making. They are often glazed, and should be $14\frac{1}{2}$ inches long and $10\frac{1}{2}$ inches broad. The *Bridgewater double roll tiles* are shown in fig. 614*a*. Three stubs are formed on the back to catch the lath. They lap over two inches, and afford good ventilation for farm buildings, with good protection from rain and snow.

Fig. 614a.

1839. The following are the *weights* of the undermentioned sizes of tiles used for various purposes:—

Paving tiles at per 100:

	cwts.	qrs.
$9 \times 9 \times 2\frac{1}{4}$ =	0 13	2
$9 \times 9 \times 1\frac{3}{4}$ =	0 9	2
$9 \times 9 \times 1\frac{1}{4}$ =	0 7	3
$9 \times 9 \times 1\frac{1}{2}$ =	9 lbs. each	
$12 \times 12 \times 1\frac{1}{2}$ =	16 „	
$12 \times 12 \times 2$ =	22 „	
$14 \times 14 \times 2\frac{3}{8}$ =	$35\frac{1}{2}$ „	
$16 \times 16 \times 2\frac{3}{8}$ =	44 „	
$18 \times 18 \times 2\frac{1}{2}$ =	$64\frac{1}{2}$ „	
$20 \times 20 \times 2\frac{5}{8}$ =	84 „	
$22 \times 22 \times 2\frac{7}{8}$ =	104 „	
$24 \times 24 \times 3$ =	133 „	
Ridge tiles 18 in., about	15 „	
10 to 14 cwts. per 100.		
„ rolled, 18 to 24 in.		
23 to 29 lbs. each.		
12 to 18 cwts. per 100.		

Malt kiln tiles

$12 \times 12 \times 2$ = 16 lbs. each

Hothouse flue tiles

$12 \times 12 \times$ = 13 „

Plain tiles	lbs. each	cwts. per 1000
$11\frac{1}{4} \times 6\frac{1}{2} \times \frac{1}{2}$ =		
$10\frac{1}{2} \times 6\frac{1}{2} \times \frac{5}{8}$ =	2·51 =	$22\frac{1}{4}$
$11 \times 7 \times \frac{5}{8}$ =	2·90 =	$26\frac{1}{4}$

Pan tiles

$13\frac{1}{2} \times 9\frac{1}{2} \times \frac{1}{2}$ = 5·25 = 47

Bridgewater double roll tiles

$16\frac{1}{2} \times 14 \times \frac{1}{2}$ to $\frac{5}{8}$ = 8·80

Paving tiles, squares		
$6 \times 6 \times 1$ =	2·16 =	$19\frac{1}{4}$
$9\frac{3}{4} \times 9\frac{3}{4} \times 1$ =	5·70 =	50
$11\frac{3}{4} \times 11\frac{3}{4} \times 1\frac{1}{4}$ =	12·42 =	111
Ditto, hexagons		
$6 \times 6 \times \frac{7}{8}$ =	1·63 =	$14\frac{1}{2}$
$6 \times 6 \times 1$ =	1·86 =	$16\frac{1}{2}$

1839*a*. The Terro-Metallic manufacture provides red, blue, and buff paving tiles. The *Adamantine clinker* is noticed in the next chapter. *White glazed* tiles of Dutch and English manufacture are used for lining the walls of baths, larders, dairies, butchers' and other shops, kitchen ranges, areas for reflected light, and other such like purposes. *Mathematical* tiles are employed for covering the vertical surfaces on the outside of walls, in imitation of brickwork, and to prevent wet being absorbed.

1839*b*. *Ornamental Pavements.* The use of hardened clay for pavement is of the highest antiquity. Our own country furnishes numerous examples of the varieties employed by the Romans. The tiles are usually made of the clay found in the immediate neighbourhood in which they have been used; and ornamented, sometimes with colour, but more frequently with merely an impressed or raised design. During the Mediæval age, encaustic and other tiles were largely employed. Many varieties of plain and ornamental tiles are now made in the Potteries, as at Broseley; also at Poole in Dorsetshire. The coarser kinds, for streets and doorways, have a red, or a buff, colour, and are prepared from the Staffordshire clay, which is found associated with coal. By mixing metallic oxides with the finer clays, blue and other colours are produced. The manufacture consists in bringing the clay into a state of fine powder, containing a certain amount of moisture; the mass is then placed in a mould of iron which it completely fills, when the ram of an hydraulic press, exactly fitting the mould, gives a pressure of from 150 to 200 tons, compressing the clay into a comparatively very small space; on being removed from the mould it is polished or smoothed off on the surface, and then it is ready for being baked in the kiln. The *encaustic* or variegated tile is composed, in the body, of ordinary red or buff clay; it is pressed in a mould under a common screw press, the mould not only producing the outer form of the tile, but also certain impressions on the face of the clay, about a quarter of an inch in depth. It is then taken out of the mould, and allowed to acquire a certain state of dryness. Devonshire or Cornish clay, coloured, is then poured over the whole surface filling the impressions, in the state of a very thick *slip*; when this has been dried to a certain extent, the slip is scraped until the face of the common clay or body is seen, the impressed spaces only being filled with the coloured matter. A layer of clay is also applied to the back, and is sometimes pierced with holes to prevent the bending of the tiles in the process of baking.

1839*c*. The *Tesseræ* are manufactured by a similar process. In Lambeth, clay being properly prepared and stained of the desired colour, as black, red, blue, &c., is made into long narrow ribbons, by means of a squeezing machine. These ribbons are cut into squares, which are placed one on another, 15 or 20 high, previously oiled to prevent adhesion. These piles are then placed upon a frame sliding in two perpendicular grooves, with fine steel wires stretched tightly across, so that by pressing the frame downwards, the wires

subdivide the slices into the square, oblong, triangular, or other shaped tesseræ required; these are then dried and baked in the ordinary way. Messrs. Minton manufacture their tesseræ by pressure as for making tiles.

1839*d*. The mode of forming tesseræ into *mosaic paving slabs* is as follows:—The tesseræ are laid face downwards on a perfectly flat slate, in the pattern or design required. The size and shape of the slab is given by strips of wood or slate fastened round the tesseræ. Portland cement is poured on the backs of the tesseræ, and two layers of common red tiles are added in cement; thus forming a flat and strong slab, which is fitted for laying down as pavement. (Hunt, *Handbook*, 1851.) The better tiles, and the larger tesseræ for pavements, are laid separately on a carefully prepared foundation of fine concrete, and then set in fine sand. The durability of a tesselated pavement consists greatly in the solidity of the foundation given to it. With a floor subjected to vibrations such a work will go to pieces. The encaustic tiles with raised patterns should only be used as wall linings, as at Granada, and never for pavements, as is sometimes done.

1839*e*. Terra-Cotta. This term has become generic for articles of an artistic character, made of clay and burnt, or of a composition in which clay forms the chief substance. The best materials are akin to those used in porcelain; but the substance burnt is quite unlike it. The clays are generally red, brown, buff, and a dull white, in colour. They may be mixed with manganese, ochres, and cobalt. Old stoneware, ground to powder, and combined with the new clays, tends to prevent large lumps of clay from warping and twisting in the drying and burning, so that, with careful management, blocks with a moulded surface 20 feet cube can be burnt of perfect form. By the mixture of felspar, ground glass, and other bodies with the clay, the fire partially vitrifies the mass, and renders it proof against the weather, and against acids and alkalies. Great care is necessary in baking the terra-cotta; for if the heat be applied too rapidly, the material cracks and the design is spoiled. The fire is, therefore, kept low at first, and gradually increased, not reaching its maximum for eight or ten days. This description of pottery is unglazed. Before the material goes into the ovens, it is in such a hard, close, and compact condition that it can be turned in a lathe, and is thus adapted to the most delicate forms which can be desired. After they are baked, the forms hold as exactly, and nearly as purely, as if they had been worked out of stone by hand. The manufacture of terra-cotta for decoration is brought at the present time to great perfection, and it possesses capabilities for being introduced to an enormous extent, but the dread of the resultant twisting of the material, if it be not properly manufactured, will always cause a preference for carved work.

1839*f*. Stoneware is a dense and highly vitrified material, impervious to the action of acids, and of peculiar strength. Until about 1836, when the duty was taken off, this material was chiefly used for common spirit bottles, oil jars, &c. The clay used is found near the coast in Devonshire and Dorsetshire. It is dug in square lumps of about 40 lbs. each, and transported in ships to London. After being perfectly dried it is ground to a powder, mixed with water, and, after being allowed to become of uniform consistency, the mass is passed through pug mills, and taken to the workmen. For making large articles, portions of the burnt material, finely ground, are mixed with the new clay; also some white sand found in the neighbourhood of Woolwich and Reigate.

1839*g*. Almost all round articles are formed by the potter, on wheels turning with the required rapidity. For articles of other shapes, the composition in a soft and plastic state is laid in plaster of Paris moulds; the porous plaster gradually absorbs the moisture from the clay, and when sufficiently firm it is removed. Some thousand articles are frequently made from one mould before it is destroyed. When thoroughly dry, the ware is placed in ovens or kilns, and exposed to a gradually increasing heat, so intense as to become, before finishing, quite white; salt is then thrown in, and being decomposed, the fumes act chemically on the surface of the ware, and fuse the particles together, giving the glaze so well known. *Stoneware* differs from all other kinds of *glazed earthenware* in this important respect, that the *glazing* is the actual material itself fused together; in other kinds of ware it is a composition in which the article is dipped while in what the potters call the *biscuit*, or half burnt state. Hunt, *Handbook*, 1851.

1839*h*. Burnt Clay Ballast. This is now extensively used for forming the foundations of the new formed roads round the metropolis, and for footpaths in the suburban gardens. The clay obtained in making the excavations for the new houses is run to a convenient locality adjacent; a log of old timber is fixed upright in the ground; a horizontal flue 6 or 8 feet long is formed with bricks on edge, with an opening on the top near the log. Shavings are laid round the post and in the flue, outside of which pieces of timber are piled in a conical form about 8 feet wide and 5 feet high; and then coated with about half a ton of coal, which is covered with the newly excavated clay to a convenient thickness. The shavings are then lighted, if the wind suit; and in a short time the top of the heap falls in, lumps of coal are then thrown in, and on them more lumps of clay. The object to be attained is to have a mass of red hot fire in the middle of the heap. For a heap of about 100 solid yards of clay, about 11 loads of breeze or ashes, and 4 tons of slack or fine coal will be needed. The heap, once fairly alight, is covered with clay. The tendency of

the fire being to burn upwards, the fireman, with a long rake, drags the outer surface downwards every time the burning heap is fed; this is done by scattering the slack over it with a shovel to quicken the fire, and the breeze is then laid on to retain it; while a fresh layer of clay is subsequently put on all over the heap. When this clay is nearly burnt through, the operation is repeated. When there is a gentle smoke all over the heap the fire is going on properly; if too little, an iron rod is pushed in to stir it up; if too much, shields must be put up to break the wind. The general form of the heap, which is cone-shaped at starting, becomes of a flattened circular top in course of being worked. It should not be made too high, as that increases the labour of wheeling the clay. When all the clay is used, such portions as are not sufficiently burnt are raked off and thrown up to the top to the greater heat: the heap is then trimmed off and left to cool.

1839*i*. When *well burnt*, the ballast may be worth the trouble; when badly done, as is usually the case, it is not much better than rubbish, in fact not nearly so good as the usual dry brick rubbish of which roads should be made. When well burnt, ground fine, and mixed with an equal portion of sand, and a less than the ordinary proportion of good lime, it makes a mortar which will set as hard as cement. The ballast may also be sifted through a 65 or 70 wire sieve, and the fine stuff, hard and clean, used for mortar or for the plasterer; the coarse and the rough, for concrete in addition to gravel. When used as *core* for a road, it should be at once covered with the Cowley or other gravel, or the clay beneath it rises up with traffic, and much rain will soon render the road as bad as though the soil had not been covered; in fact it turns into mud, and the scamping builder finds it pays to mix his bad lime in the roadway dirt, and to use the mixture for mortar.

SECT. XI.

LIME, SAND, WATER, MORTAR, CONCRETE, AND CEMENT.

1840. Lime has not been found in a native state; it is always united to an acid, as to the carbonic in chalk. By subjecting chalk or limestone to a red heat it is freed from the acid, and the lime is left in a state of purity, and is then called caustic or quicklime, which dissolves in 680 times its weight of water. It is not our intention here to enter into any account of either of the theories relative to the formation of lime, facts being of more importance to the architect in its employment than the refined fancies of the scientific chemist. The calcareous minerals are mostly distinguished by their effervescing with, and dissolving in, an acid, as also by their being easily scratched or cut with a knife. In respect of the lime obtained from chalk, Dr. Higgins (in his work on *calcareous cements*, Lond. 1780) says, "It should be observed, that the difference between chalk lime and the lime obtained from the various limestones, chiefly consists in the greater retention or expulsion of the carbonic acid gas contained in them."

1841. An account of the stone from which lime may be obtained in the different counties of England would unnecessarily extend this article; we shall, therefore, after observing that the use of marble for burning to lime would be too expensive, state the varieties of limestone as, 1. the compact; 2. the foliated; 3. the fibrous; and, 4. the peastone. The compact limestones are of various colours, in hues inclining to grey, yellow, blue, red, and green, and to a smoky sort of colour besides. It is usually found massive, often compounded with extraneous fossils, particularly shells. Its internal appearance is dull, the texture is compact, the fracture small, fine, and splintery; fragments indeterminately angular, more or less sharp-edged; semi-hard, sometimes soft, brittle, and easily frangible. Specific gravity varies from 2500 to 2700, and it is composed of lime, carbonic acid, and water, mostly with a portion of argyl and oxide of iron, and sometimes of inflammable matter.

1842. The foliated limestones are such as calcareous spar, statuary marble, &c.; the fibrous limestones, such as satin spar; and the peastone, another species of spar. It may be remarked, that the various sorts of marble, chalk, and limestone may be divided into those which are nearly pure carbonate of lime, and those containing in addition from one twentieth to one twelfth of clay and oxide of iron. "Though the best limestones are not such as contain the greatest quantity of clay, yet," observes Mr. Smeaton, "none have proved good for water building, but what, on examination of the stone, contained clay; and though," he continues, "I am very far from laying down this as an absolute criterion, yet I have never found any limestone containing clay in any considerable quantity, but what was good for water works, the proportion of clayey matter, being burnt, acting strongly as a cement; and limes of this kind all agree in one more property, that of being of a dead frosted surface on breaking, without much appearance of shining particles."

1843. Among the strongest limes, such as will set under water, those most in use in the metropolis are called *grey stone limes*, and are procured from Dorking, Merstham, and the vicinity of Guildford in Surrey. The Dorking and other limes of that part are burnt from

a chalk formation so extremely hard that it is quarried even for the purposes of masonry. Those of Mersthам particularly are obtained from an indurated chalk marl (clay and chalk) which is so hard that it partakes of the nature of stone.

1843*a*. The known property of the *blue lias* formation for setting under water renders it an invaluable material in the hands of the architect. In the neighbourhood of Bath it is called Bath brown lime, and when prepared for cementing with metallic cement, is said to be *wind slaked*; that is, after burning, it is placed in roofed sheds open at the sides, and the atmosphere is thus introduced to act upon it. The colour of the *lias*, previous to burning, is blue; after it has passed the kiln, it is of a rich brown colour.

1843*b*. It is extremely difficult to give any quantitative analysis of the *blue lias*. Every layer in a quarry will be found to differ more or less decidedly from those above or below it. The beds extracted for burning into lime may be said to consist principally of carbonate of lime (perhaps as much as 90 per cent.) in combination with silicate of alumina, some oxide of iron, potash, and a small quantity of sand, in mechanical mixture; but the ingredients insoluble in nitrous acid, such as silicate of alumina and sand, vary in every imaginable proportion between 5 and 18, or at times 20, per cent. The best blue lias lime is obtained from the beds of calcareous marl which contain about 16 per cent. of silicate of alumina; such as is brought from Aberthaw in South Wales, Watchet in Somersetshire, and Barrow, in Leicestershire: the limes from Whitby, in Yorkshire, and from Lyme Regis, in Dorsetshire, are nearly equal to them. The principal objection to this lime as used in London is founded upon the large proportion of underburnt or unburnt stone or *core* left in it. The weight of an imperial bushel of Aberthaw lime of a superior quality is 85 lbs.

1843*c*. The magnesian limestone of Sunderland lies north-west of the red sandstone. In the vicinity of South Shields, in the county of Durham, the formation becomes extensive, and is to be traced to the Tees below Winston Bridge. The Whitby quarry near Callercoats has been described in the 4th volume of the *Geological Transactions*. The Sunderland limestone is of a bronze colour, and from containing inflammable matter, does not require so much fuel to convert it into lime. The naturally hydraulic limestone of Arden found near Glasgow, in Scotland, has been largely used in the local dock works, in the proportion, for concrete, of one part of ground lime, one part of iron mine dust, one part of sand, and four and a half parts of gravel and quarry chips. Pure hydraulic lime, as it is called, manufactured (in Flintshire) from the best Halkin Mountain limestone, is much used in the dock works at Liverpool and Birkenhead.

1843*d*. *Hydraulic limes* have been thus classed:—If they harden under water in periods varying from fifteen to twenty days after immersion, they are slightly hydraulic; if from six to eight days, simply hydraulic; if from one to four days, eminently hydraulic. Hydraulic works frequently burst from the *slaking* of the lime which has not been properly prepared for its office. It should be all hydrated before placing, and this requires more time than the slaking of ordinary lime; the heat developed is much less than in any other lime.

1844. Before limestone is burnt it seems to possess no external character by which a distinction can be made between the simple and the argillo-ferruginous limestones; whatever the colour of the former, they become white when burnt, whilst the latter partake more or less of a slight ochrey tint. Brown lime is the most esteemed for all sorts of cements, whilst for common purposes the white sorts, which are more abundant, are sufficiently useful. In England, the limestones in colour generally incline to a red or blue, and those which are found firm, weighty, and uniform in texture are to be preferred. Masses broken from large rocks and beds on the sides of hills, and those when newest taken and deepest dug, are most to be valued.

1845. The process of analysing limestones is so eminently useful to all concerned in building, that we cannot refrain from transcribing the method used by Smeaton in his own words. "I took about the quantity of five pennyweights (or a guinea's weight) of the limestone to be tried, bruised to a coarse powder, upon which I poured common aquafortis, but not so much at a time as to occasion the effervescence to overtop the glass vessel in which the limestone was put, and added fresh aquafortis after the effervescence of the former quantity had ceased, till no further ebullition appeared by any addition of the acid. This done, and the whole being left to settle, the liquor will generally acquire a tinge of some transparent colour; and if from the solution little or no sediment drops, it may be accounted a pure limestone (which is generally the case with white chalk and several others), as containing no uncalcareous matter in its composition. When this is well settled, pour off the water, and repeatedly add water in the same way, stirring it, and letting it settle till it becomes tasteless. After this, let the mud be well stirred into the water, and without giving it time to settle, pour off the muddy water into another vessel, and if there be any sand or gritty matter left behind (as will frequently be the case), this collected by itself will ascertain the quantity and species of sabulous matter that entered into the texture of the limestone. Letting, now, the muddy liquor settle, and pouring off the water till no more can be got without an admixture of mud, leave the rest to dry, which,

when of the consistence of clay, or paste, is to be made into a ball, and dried for further examination."

1846. There are many sorts of kilns for burning limestone, varying in form with the fuel employed, and the combination of the process itself with some other, such, for instance, as making coke, and sometimes bricks. The limestone, however, is generally burnt in kilns whose plans are circular and section resembling an inverted truncated cone; of late more frequently made spheroidal. The heat is in either case obtained from a fireplace under the limestone, which rests on bars, that can, when the kiln is a perpetual one, egg-formed, or a draw kiln, be removed to let out the lime as it is burnt, whose deficiency, on extraction, is supplied by fresh stone at the top of the kiln. *Sod kilns* are sometimes used for lime burning. These are formed by excavating the earth in a conical form, and then building up the sides as the earth may require. In using these the limestone is laid in with alternate layers of fuel to the top of the kiln, and the top being covered with sods, so as to prevent the heat from escaping, the fire is lighted and the process effected. The lime is not removed till it is thoroughly cool. This mode is a tedious operation, and, because of the quantity of fuel consumed, far from economical. In the common lime-kiln, the fire is never suffered to go down, but as the well-burnt lime is removed, fresh lime is supplied. There is a species of kiln called a flame-kiln, in which the calcination is effected with peat. In this kiln the process of burning bricks is carried on at the same time. The loss of limestone by burning is about four-ninths of its weight, shrinking, however, but little. When completely burnt, it falls freely, in slaking, into powder, and then occupies about double its previous bulk.

1847. Lime burners have made the important observation, that the quantity of stone calcined and the quantity of fuel expended depend on the quality of the fuel. Hence the kiln is constructed with reference to the fuel, rather than to the nature of the stone to be calcined. Limestone, taking an average time, requires burning about sixty hours to reduce it to lime, when the heat is strong and well regulated: but of course no general rule can be laid down, as different species will require different periods of time. The principal object to be accomplished is the expulsion of the carbonic acid gas which enters into its composition.

1848. The lime generally most esteemed is that which heats most in slaking, and slakes the quickest, falling into a fine powder. If there be among it coarse unslakable lumps called *core*, that will not pass through the screen, either the stone has not been sufficiently burnt, or it originally contained extraneous matter; this not only indicates defect in quality, but that it will be, as they more or less abound, more costly in use. Lime in slaking absorbs a mean of 2·5 times its volume; and 2·25 its weight of water. The hydraulic limes absorb less water than the pure limes, and only increase in bulk from 1·75 to 2·5 times their original volume. Slaked lime is a hydrate of lime.

1849. From the experiments of Mr. Smeaton and of Dr. Higgins, it is sufficiently proved that, when chalk or stone lime is equally fresh when used, the cementitious properties of both are nearly, if not quite, equal; but from the circumstance of quicklime absorbing carbonic acid more or less in proportion as its texture is solid or spongy, so it gradually parts with its cementing nature, becoming at length altogether unfit for the purposes of mortar. Thus, though each of the sorts may be equally good, if properly burnt and quite fresh from the kiln, yet from the chalk lime so much more easily and rapidly taking in the carbonic acid than stone lime does, it is not so fit for general use; and, indeed, now the metropolis is so well supplied with the harder chalk and stone limes, there is no excuse for its use, and it should in sound building be altogether banished.

1850. The following table, from Smeaton, contains a list of the limestones he examined on the occasion of building the Eddystone Lighthouse:—

Species of Stone.	Proportion of Clay.	Colour of the Clay.	Reduction of Weight by burning.	Colour of Brick made of such Clay.
Aberthaw, on the coast of Glamorganshire	$\frac{3}{23}$	Lead colour	4 to 3	Grey stock brick.
Watchet, small sea-port in Somersetshire	$\frac{3}{25}$	Do.	4 to 3	Light colour, reddish hue.
Barrow, Leicestershire	$\frac{3}{11}$	Do.	3 to 2	Grey stock brick.
Long Bennington, a village in Lincolnshire	$\frac{3}{22}$	Do.	- -	Dirty blue.
Sussex Church, near Lewes in Sussex	$\frac{3}{16}$	Ash colour	3 to 2	Ash colour.
Dorking, Surrey	$\frac{1}{17}$	Do.		
Berryton grey lime, near Petersfield, Hants	$\frac{1}{12}$	Do.		
Guilford, Surrey	$\frac{3}{19}$	Do.		
Sutton, Lancashire	$\frac{3}{16}$	Brown		

1851. Sand should by all means, if possible, be procured from a running clear stream, in preference to that obtained from pits. It is cleaner and not so connected with clayey or muddy particles. About the metropolis it is the practice to use (and an admirable material it is) the sand of the Thames procured from above London Bridge. This sand has acquired a deserved reputation among the architects and builders of the capital. It contains, however, a vast portion of heterogeneous matter, such as calcareous fossil, quartzose, and flint sands, particles of coal alluvium, and much iron. The sharp drift sand of the Thames, therefore, before mixing with the lime, should be well screened and washed.

1852. If *pit sand* only can be procured, it should be repeatedly *washed*, to free it from the earthy and clayey particles it contains, until it becomes bright in colour, and feels gritty under the fingers. Smeaton has stated that clay, even in very small quantities, materially interferes with the hardening of mortar, and disposes it to perish in a few years. When the architect is obliged to use *sea sand*, it must be well washed in fresh water until the salt is entirely removed; otherwise the cement for which it is used will never dry. So small a quantity as 3 per cent. of salt causes great inconveniences. Whenever the weather is dry, the walls will show an efflorescence on the inside or outside. This, when there is damp in the atmosphere, will collect moisture, causing the wall to look wet, and will throw off any paper placed on it. In one case where a builder, being in close proximity to the seaside, indiscriminately employed sea sand for outside and inside purposes, the saline property soon told its own tale by introducing the rot to all adjoining timber.

1852*a*. It will be well to notice here that Professor Wilson, of the Edinburgh Laboratory, made in 1848 a report on the use of *sea sand* in mortar in a house, No. 10 Randolph Crescent, which was said to be damp from the use of it. On analysis he found that the mortar contained only 1-10,000th part of its weight of the chloride of magnesium, a highly deliquescent attracting substance. But he considered that the setting of the mortar mechanically enveloped and locked up within its mass the substance in question; and further, that it might chemically combine with the lime of the mortar to form a compound not readily to be dissolved in water. It was also thought that in consequence of a chemical action taking place between the lime in the mortar and the chlorine derived from the sea water contained in the sand, chloride of calcium (muriate of lime) would be produced, and this being a deliquescent substance, would attract moisture and render the walls damp. The amount, however, of chlorine in specimens of sea sands, was found to vary from a 2,174th to a 549th part of their weights; the mean amount was a 1,204th part. The quantity in the mortar was so minute that it could not sensibly produce the effects of damp. The mechanical envelopment of the chloride of calcium in the mortar would also shut up this deliquescent substance from moisture, and conduce to dryness. A further substance in sea sand, is chloride of sodium (common salt), and if the chlorine of this be transferred to the lime to form chloride of calcium, the sodium will become converted into carbonate of soda. These substances may co-exist in the mortar, but as soon as they are separated from it, and diffused through the stone, or brought to its surface, the carbonate of soda will convert the chloride of calcium into carbonate of lime (chalk) and become itself chloride of sodium (common salt). A consideration of these facts led the analyst to affirm that the apprehension that chloride of calcium, as derived from sea sand, would render the house damp, was altogether chimerical. On an analysis of some of the pit sands in the neighbourhood, he found that one of them contained almost the same quantity of chlorine as in the sea sand, although no charge was made against it. It does not admit of doubt, he reported, that, other things being equal, sea-sand mortar will dry more quickly and keep more thoroughly dry than will pit-sand mortar; this sand, it must be noticed, contained about 13 per cent. of earthy matter, and was therefore not so *pure* as the sea sand.

1852*b*. Although all the professional publications of late years have described the bad effects likely to result from the use of unwashed *pit sand*, builders in the outskirts of the metropolis have taken to use road sweepings in lieu of sand, and this even without having washed it to free it from those impurities not only detrimental to its making good mortar, but also to the building itself, as it may be the cause of introducing the dry rot. Lately we have noticed a case in the professional journals where the lime, such as it was, was "mixed with a large proportion of garden mould and mud, the bricks being of an inferior quality and insufficient strength." We have already noticed the use of road dirt (*par.* 1839*i*.) In another case "the composition with which the portions of bricks were held together consisted of soap lees with a few small limestones and dirt." The interests of the poorer classes should be better protected.

1852*c*. *Metallic sand* for cement was introduced about 1843. It was sold in coarse or fine powder as required, to be mixed up with blue lias lime for joining bricks and stone, for concretes, for face work, or for moulded work. 1 measure of the sand, 1 of lime, and 6 of gravel were the proportions used in the foundations of the new Houses of Parliament, and at the great tunnels of the Birmingham railway. It has also been used for malt-house

steeping troughs, and floors; for the latter purpose it can be polished. For exterior facings, as stucco, it was used at 57 Coleman Street; and at the Alfred Insurance Office, Lothbury: the latter building has lately (1866) been pulled down. The marine turret at Herne Bay was also coated with it.

1853. WATER. Dr. Higgins recommends the use of lime-water for the composition of mortar. This, in practice, would be impossible. The water used, however, for the incorporation of the lime with the sand should be soft and pure. Mortar and concrete have both been recommended to be made up with *hot* water; with the latter especially, when it is desirable that it should set immediately: concrete thus made has been found exceedingly hard. Its employment with mortar dates from before 1520. It is probable that water charged with iron, as at Tunbridge Wells; a solution of chalk, as in Hertfordshire; sulphuretted hydrogen, as at Harrowgate; and salts, as at Epsom and elsewhere; may all affect lime when combined with it. Smeaton stated that he could not discover any difference in the strength of mortar, whether it were made with sea, or with fresh, water.

1854. In forming MORTAR from lime, it must, when slaked, be passed through a sieve leaving only a fine powder, an operation usually performed with a quarter inch wire screen set at a considerable inclination to the horizon, against which the lime is thrown with a shovel after slaking. That which passes through is fit for use; the core falling on that side of the screen against which the lime is thrown, being entirely rejected for the purpose in question, though it is an excellent material for filling in the sides of foundations under wood floors where they would otherwise be next the earth, and the like. The sifted or screened lime is next to be added to the sand, whose quantity will vary as the quality of the lime, of which we shall presently speak. In making mortar, there is no point so important, as respects the manufacture itself, as the well tempering and beating up the lime with the sand after the water is added to them. In proportion, too, as this is effectually done, will a small proportion of lime suffice to make a good mortar. The best mode of tempering mortar is by means of a pug-mill with a horse-track similar to the clay-mills used for making bricks. But if such cannot be had, the mortar should be turned over repeatedly, and beaten with wooden beaters, until it be thoroughly mixed. That this process should be carefully performed, will appear of the more importance when it is considered that it thereby admits a greater proportion of sand, which is not only a cheaper material, but the presence of it renders a less quantity of water necessary, and the mortar will consequently set sooner: the work, too, will settle less; for as lime will shrink in drying, while the sand mixed with it continues to occupy the same bulk, it follows that the thickness of the mortar beds will be less variable.

1855. Vitruvius recommends that mortar should be beaten with wooden staves by a number of men before being used. Smeaton reckoned it a fair day's work for a labourer to mix and beat up two or three hods of mortar for use. The pug-mill does this now in two or three minutes. Pliny expressly states that "in ancient specifications for buildings it was provided that no slaked lime less than three years old should be used by the contractor." Covent Garden Theatre was built in 1808–9 with lime while still hot from the kiln: when the walls were demolished a few years since, the mortar was found to be hard and solid. It was so used at Tothill Fields prison. At the new Royal Exchange, the lime was to be thoroughly and freshly burnt, to be kept in an enclosed shed, and no more mortar to be made than was sufficient for each day's consumption.

1856. In most of the public works executed in Great Britain of late years, the proportion of lime to sand is as 1 to 3; and when the former is made from good limestone, the sand is by no means too much in proportion. Dr. Higgins, in his experiments, has gone so far as to recommend 7 parts of sand to 1 of lime, which, for mortar, is perhaps carrying the point to the extreme. It may be taken as an axiom, that no more lime is necessary than will surround the particles of sand. C. H. Smith has stated, (*Builder*, 1865, p. 41), that if each particle of sand be covered with lime about the thickness of an ordinary coat of paint, he should be disposed to consider such an amount as very near the perfection of quantity. A superabundance of lime or sand, no matter how good it may be, is, under any circumstances, objectionable.

1857. Various opinions have long been entertained by chemists and others respecting the effect of sand and lime upon each other in the formation of mortar. The general impression is, that the slaked lime and sand in contact have a chemical affinity for each other; that the lime decomposes the surface of the sand, and the atoms or molecules interpenetrate each other, forming a sort of silicate of lime. This is an extremely ingenious theory, says C. H. Smith, but it has never been proved. It has been stated, he also adds, that the hardening of mortar arises from the presence of carbon and oxygen formed into carbonic acid, which is absorbed by the lime; but the source from whence the carbon is obtained is at present a mystery. Oxygen is abundant in the composition of water and atmosphere, and that quicklime has an astonishing affinity for it, is evinced by the practice of dusting steel goods with it when not in use, to prevent their rusting; or that of placing a small lump of it in any box or case containing such goods. Bricklayers

smear their trowels with the mortar before leaving off work ; and in the *Parentalia*, it is noticed that "in taking out cramps from stonework at least 400 years old, which were so bedded in mortar that all air was perfectly excluded, the iron appeared as fresh as from the forge."

1858. Various additions are made to mortar, in order to increase its hardness and tenacity ; such as coal and wood ashes, forge scales, roasted iron ore, puzzuolana, and the like. The property of hardening under water or when excluded from the air, conferred upon a paste of lime, is effected by the presence of certain foreign substances, as silicon, alumina, iron, &c., when their aggregate presence amounts to one tenth of the whole. Artificial hydraulic limes do not attain, even under favourable circumstances, the same degree of hardness and power of resistance to compression as the natural limes of the same class.

1858*a*. As Burnell, in *Limes, Cements, &c.*, 1857, p. 71, says—"It is often a matter of importance to know the power of resistance of mortars; but as they differ within a very large range, it is not easy to state it very precisely. The best experiments, however, show that we may safely calculate upon a resistance of 14 lbs. per inch superficial for its cohesive force; of 42 lbs. to a crushing force; and of $5\frac{1}{4}$ lbs. to a force tending to make the particles slide upon one another. It would not be safe to expose new works to greater efforts than those which could be included within the above limits." In the construction of a wall, whether of brick or rough stone, it should be clearly understood that there is an important distinction between mere drying and the ultimate process of induration. The mortar may become sufficiently set, dry, and solid, in a few days or weeks, to enable the wall to bear a very considerable weight and pressure ; but it does not acquire the maximum degree of hardness till after the lapse of many years and even of centuries. All cements and limes tend to reassume a state of carbonization similar to that in which they existed in the stones from whence they were extracted ; they only do so to a very imperfect degree. The saying that lime at a hundred years is but a child, is perfectly true. Cements on the contrary harden very rapidly, but we have no instances of their acquiring the strength o the original stone.

1859. The *cendre de Tournay* is used in the Low Countries. This is an article procure from the lime-kilns bordering the Scheldt. The lime of this district contains a considerabl portion of clay mixed with iron ; and the pit-coal with which it is burnt contains a larg quantity of an argillaceous schist, impregnated with iron. After the lime is taken out o the kilns, there remains the *cendre*, about one fourth of which consists of burnt lime-dust and three fourths of coal-ashes. This material is sprinkled with water to slake the lime and well mixed together, and put into a proper vessel and covered over with wet earth. In this state it is kept for a considerable time ; and when taken out, and strongly beaten up for half an hour with an iron pestle in a wooden mortar or trough, it is reduced to a soft pasty consistence ; it is then spread out for several days in a shady place, and the operation of beating repeated: the oftener this is done the better, except it should become unmanageable from being too much dried. In a few minutes, this cement, when applied to brick or stone, adheres so firmly that water may be immediately poured over it ; and if kept dry twenty-four hours, it afterwards receives no injury even from the most violent action of a flowing stream.

1859*a*. In London, a mortar made of lime with sea-coal ashes from a smith's forge mixed with the iron scales, and called *blue* mortar, is used for covering parts of buildings much exposed to the weather ; and if prepared with similar labour and attention, it might, in a great degree, possess the valuable properties of the mortar of the Scheldt, just mentioned.

1859*b*. Common *ashes* mortar is made by mixing two bushels of newly slaked lime and three bushels of wood ashes, which, when cold, must be well beaten, in which state it is usually kept for a considerable time, and indeed it improves by keeping if beaten two or three times previous to using it. This mixture is superior to terras mortar in resisting the alternate effects of dryness and moisture, but not comparable with it under water.

1859*c*. *Brick* and *tile* and *burnt clay ballast*, each well burnt and ground to a powder, combined with rich lime, possesses hydraulic energy. *Pulverised silica* burned with rich lime produces hydraulic lime of excellent quality. In some experiments made by MM. Chatonoy and Rivot, this lime hardened under water in from three to four days, and acquired in twenty-two months a hardness superior to Portland cement. The weight of the powdered lime never exceeded four times, and was never less than one half that of the powdered silica. Brick-dust mortar used to be considered in some cases better than mortar made of terras, for unless the terras was always wet it was not thought better than common mortar made of lime and sand ; 2 bushels of hot lime, i.e., fresh slaked lime, added to 1 bushel of brick-dust made from red stock bricks, was to be well beaten and worked up before using, with but little water: the longer it was beaten the better it became. The dry brick rubbish of old walling broken down and *sifted*, was considered better than sand, as less sand is required, and it might be safely used in frosty weather. A tract on Old Charing Cross, mentions that it was "so cemented with mortar made of purest lime,

callis sand, white of eggs, and the strongest wort, that it defied all hammers and hatchets whatsoever." The mortar used in bishop Gundulph's works at Malling and Rochester is described by B. Ferrey as consisting of a sort of tufa found only in the cliffs at Dover, which appears to have been exclusively used in his works.

1859*d*. *Slag* is applied to the vitrified earths left in furnaces, either for glass or iron. *Scoriæ* are the lighter, more porous, and less vitrified earths arising from the puddling and refining of iron. The *cinders* used are the earthy residues derived from the combustion of coal. When ground into powder, the two former, which contain a large proportion of the mineral oxides, make very good mortars if mixed with middling or perfectly hydraulic limes. Cinders appear to render the rich limes moderately hydraulic when properly mixed. They require a large quantity of water to render perfect the crystallization of the hydrate of lime. All these mortars may be usefully employed for works out of water.

1859*e*. The stones whereof the *Dutch terras* is made are found in the neighbourhood of Liege, and also, we believe, at Andernach on the Rhine, from the size of a pea to that of a middle-sized turnip. From their being brought down the rivers to Holland the cement has been called Dutch; the only operation they undergo in that country is the reduction of them to a coarse powder by means of mills. They are beaten by iron-headed stampers on an iron bed till they will pass through a sieve whose wires are about one eighth of an inch apart. This cement is sent from Holland in casks. *Trass*, *terras*, or *tarras*, is a blue-black trap. It is obtained from pits of extinct volcanoes, and has nearly all the distinguishing elements of puzzuolana, resembling it in composition, and in the requirements of its manipulation, having to be pulverised and added to rich lime to develope its hydraulic properties.

1859*f*. The *Puzzuolana*, or *terra Puteolana* of the Italians, which, as well as the last-named cement, has been almost if not quite superseded by the introduction of the Roman cement, is brought from Civita Vecchia. Its name is however derived from Puzzuoli, where it is principally found, though produced in other parts of Italy, in the neighbourhood of extinct volcanoes. It suddenly hardens when mixed with one third of its weight of lime and water, forming a cement more durable under water than any other. Bergman found 100 parts of it to contain 55 to 60 parts of siliceous earth, 20 of argillaceous, 5 or 6 of calcareous, and from 15 to 20 of iron; this last constituent is considered to be the cause of its property of hardening under water. The iron decomposes the water of the mortar, and thus in a very short time a new compound is formed. According to Vitruvius, when used for buildings in the water, 2 parts of puzzuolana were mixed with 1 of mortar. Artificial puzzuolana may be made by slightly calcining clay, and driving off the water of combination at a temperature of 1,200°.

1859*g*. Subsequently to the use of this material from Puzzuoli, a similar material has been found near Edinburgh; and in the Vivarais, a site of extinct volcanic action in the centre of France. Its aspect and colour, however, vary very much even in the same locality. Berthier gives the following analysis of two of these materials:—

	Puzzuolana from Civita Vecchia.	Terras from Andernach.
Silica	·445	·570
Alumina	·150	·120
Lime	·088	·026
Magnesia	·047	·010
Oxide of Iron (in a slight state of magnetism)	·120	·050
Potash	·014	·070
Soda	·040	·010
Water	·092	·096
	0·996	0·952

1859*h*. In the use of *blue lias* lime for mortar, workmen ignorant of its qualities invariably spoil it. In important works the lime should be supplied in an unground state, to prevent the *core* being mingled with the good lime. In slaking, the lumps should be broken into pieces of about the size of a nutmeg; then immersed upon a sieve in water, and kept therein until air bubbles freely rise to the surface: the lime so wetted is to be left in a heap, and covered with damp sand, for twenty-four hours. At the expiration of that time it should be screened and mixed with sand and the least possible quantity of water. When slaked, it does not sensibly increase in bulk, unlike the ordinary chalk or stone lime of the neighbourhood of London. The best descriptions of blue lias lime will not bear more than 1½ parts of sand to 1 of lime. Wood, of Bath, in his work on *Cottages*, 1788, has stated that "blue lias lime mixed with coal ashes in the manner prescribed by M. Loriot, will make the hardest cement I ever saw, as I have found by various experiments; it will hold water, resist frost, harden in a few hours in water, and will bear a very

good polish. Coach or carriage ways are laid or pitched with blue lias, which wears very well, though it will not bear the frost."

1859*i*. A very useful *hydraulic mortar* for executing sea-walling, consists of 1 part of chalk lime, or of Halkin lime, with one part of puzzuolana from Civita Vecchia, and 1½ parts of sand; but the value of this mixture depends upon the influence exercised by the puzzuolana on the setting of the lime. A mixture of the natural calcareous cements, or of Portland cement with sand, is another good mortar. The presence of sulphate of lime in any composition intended to resist the action of sea water would be fatal, as it crystallises at a different rate of rapidity, and it is more easily soluble than the carbonate of lime. French authorities lay particular stress on the following qualities for the formation of good hydraulic mortar: I. It is essential that the materials should be perfectly pulverised before mixing, so that the combination may be as perfect as possible. II. Sufficient free lime must be present to allow the carbonic acid in the water to combine with it, and form a protective coating of carbonate. III. Long soaking of the materials is advisable, in order that the chemical combinations necessary for the ultimate stability of the mortar may take place before it is actually used.

1859*k*. Mr. Smeaton discovered, by a course of experiments, that the scales (grey oxide of iron) that fly off under the forge hammer from red hot iron, pulverised, sifted, and mixed with lime, form an admirable cement, equal to puzzuolana. He found, in pursuing his experiments, that roasted iron ore produced an effective water cement, by using a greater proportion of it than either terras or puzzuolana. Equal quantities of iron scales and argillaceous lime, with half the quantity of each of these of sand, produced a cement in every respect equal to terras mortar. If pure carbonate of lime be used, equal parts of each of the ingredients ought to be incorporated. We do not think it necessary here to give any account either of Loriot's cement, or that proposed by Semple: neither are to be depended on: indeed the first, as a water cement, is of inferior utility, and very little better than common mortar dried before the admission of water upon it.

1860. *Grout*, or *liquid mortar*, is nothing more than common mortar mixed with a sufficient quantity of water to make it fluid enough to penetrate the interstices and irregularities of the interior of brick walls, which common mortar will not reach. The mortar whereof it is made will bear 4 of sand to 1 of lime, but it should be thoroughly beaten. It may be kept a little longer, whereby its quick setting will be facilitated.

1861. Concrete is a compound of ballast, or stone chippings, and lime mixed together. It is so called from the speedy concretion that takes place between these particles. If, however, *gallots* or small stone chippings are used, sand in a large proportion to the lime must be used. The use of concrete was well known at an early period; it is mentioned by De Lorme in his work published in 1568; and it is by no means, therefore, a discovery of modern days. Wherever the soil is soft, and unequal for the reception of the foundations of a building, the introduction of concrete under them is an almost infallible remedy against settlement. The Thames ballast, commonly used for concrete, is a mixture of sand and small stones. With this, and lime in the proportion of never less than 4 to 1, and never properly exceeding 9 to 1, of stone lime, or such as is known to set hard in water, a mixture is made. The lime is generally used in powder, and the whole being shovelled together, it is wheeled in barrows to a stage over the spot where it is to be used, and let fall into the trench dug out for the reception of the foundation. The greater the height the concrete is made to fall, the sounder and stronger it becomes. It must always be recollected that no more lime is necessary than with the thinnest coat to surround the particles of the ballast, and that therefore the size of the pebbles or stones should influence the quantity of the lime. As the ground is more or less to be trusted, the thickness of the concrete must be regulated; when used on the best ground, a foot in thickness will be sufficient; while on the worst, as many as four feet or more may be required. The upper surface being levelled, it is usual to lay on it a tier of Yorkshire stone landings, for the reception of the brick-work or mason's work: in some cases, after carrying the wall a certain height, a second tier of landings has been introduced. When the soil is watery, no water should be put to the concrete, but the ballast and lime merely mixed and tumbled in. The usual practice of making concrete as above stated, is objected to by many practitioners, who recommend that the French method of making *béton* should be followed in lieu of it.

1862. In forming concrete, the stones or pebbles used should never exceed the size of a hen's egg, of which 2 parts may be combined with 1 part of the smaller substances used; this makes it about equal to Thames ballast. It has been calculated, that as the lime absorbs the water, and with the sand fills up the interstices of the larger material, if the proportion of the lime be about one eighth of the ballast, then 3¾ cubic feet of ground lime, and 30 cubic feet of ballast, with a sufficient quantity of water to effect the admixture (and this is generally rather less than a gallon to a cubic foot of ballast, or than equal measures of water and lime), will be required to make 27 cubic feet of concrete; that is, there is a loss of bulk equal to all the lime, and of about 10 per cent. of the ballast. But some experiments made in 1857–8, in which the present editor assisted, showed that the same measure

which gave a cubic yard of ballast, held precisely the same ballast *with the addition of* one sixth in bulk of ground stone lime made with it into concrete, besides about fourteen pails of water; and likewise tended to disprove the assertion that concrete swells in setting. This cubic yard of concrete weighed 27 cwt. In estimating, allowance must be made for the loss of material.

1862*a*. Expansion taking place in concrete made of *unground* lime, during its slaking, has been taken advantage of by G. L. Taylor in the underpinning of some walls at Chatham, as detailed in the *Transactions* of the Institute of British Architects, 1835. This expansion has been found to average about $\frac{3}{8}$ of an inch for each foot in height, and the size thus gained the concrete never loses. Care must be taken when using it for floors and for the spandril of arches, to allow sufficient space, and to lay it in such a way that this increase may take place without thrusting out the walls, as has occasionally happened. In old malt houses in the West of England, with concrete floors 5 to 6 inches thick, stone walls 2 feet 6 inches to 3 feet thick have bulged out 3 or 4 inches on each side by the expansion of the concrete, as also noticed in the *Transactions* of the above named society, 1854, p. 74. When *ground* lime is used the assertion that concrete swells is very questionable, as stated in the previous paragraph.

1862*b*. For water works required to set rapidly, an excellent concrete may be made by a mixture, the proportions of which were found by Treussart as follows:—30 parts of hydraulic lime, very energetic, measured in bulk, and before being slaked; 30 parts of terras of Andernach; 30 parts of sand; 20 parts of gravel; and 40 parts of broken stone, a hard limestone. These proportions diminish one fifth in volume after manipulation; the mortar is made first. When the Italian puzzuolana is used, the proportions should be 33 parts of lime, as before; 45 parts of puzzuolana; 22 parts of sand; and 60 parts of broken stone and gravel. The first of these concretes should be employed immediately it is made; the second requires to be exposed about twelve hours before it is put in place. When burnt clay or pounded bricks are used, 30 parts will suffice, but this mortar must not be used in sea water. If only rich, instead of hydraulic, limes be used, the quantity of the natural or artificial puzzuolanas must be increased, and that of the stones and gravel be decreased. (Burnell, *Limes, &c.*)

1862*c*. After many experiments M. Kuhlmann recommends a cement composed of 30 parts of rich lime, 50 of sand, 15 of uncalcined clay, and 5 of powdered silicate of potash, as having all the requisite hydraulic properties, especially for cisterns intended for spring water. In marine constructions care should be taken to add an excess of silicate to those portions of cement which are exposed to the immediate contact of the sea.

1862*d*. The object to be aimed at in making *hydraulic concrete*, is to give such a sufficiency of mortar as will produce the aggregation of the whole mass of rough rubble materials. In Portland cement concrete for instance, the proportions for the mortar may be 1 of cement to 3 of sand, and this mortar may then be mixed with 6 parts of ballast or shingle. In blue lias lime concrete, the proportions may be 1 of unground lime to 2 or $2\frac{1}{2}$ of sand, and this mortar may be mixed with 3 or 4 parts of ballast; and it must be understood in all cases that the mortar must be made first, and that it then should be thoroughly incorporated with the ballast or shingle. This concrete as used at the recent extension of the London Docks by Mr. Rendel, consisted of 1 part of blue lias lime with 6 parts of gravel and sand. The proportions for the blocks of the mole at Marseilles, were 3 parts of Theil lime to 5 parts of sand mixed up into mortar, and then added to 2 parts of broken stone.

1862*e*. *Béton*, or concrete, as made in France, is invariably composed as follows:—I. The mixture of lime and sand, either by hand or by a pug-mill, as for ordinary mortar. Great importance is attached to the choice of the lime and to the mode of slaking it; and if a sufficiently good one cannot be obtained, artificial puzzuolanas are introduced. The *mode of slaking* is prescribed in the specification according to the nature of the lime, instead of being left to the choice of the workmen. II. The *mortar* so prepared is then well mixed by rakes with broken stones or ballast in such proportions as shall ensure its filling up the intervals between them; the volume having been ascertained by immersing the stones in a known quantity of water. These spaces are equal to about 0·38 to 0·46 of the cubical contents of the vessel; but in practice, about one fourth more mortar is added than necessary to ensure solidification of the mass, especially when the *béton* is intended to resist water pressure. III. The material is then wheeled to its situation and rammed down carefully until the mortar begins to work up to the surface.

1862*f*. In an English patent, 1859, No. 2757, M. Coignet, of Paris, argues that the tenacity of mortar is not produced as hitherto supposed by the formation of silicate of lime and alumina, but by the crystallisation of lime. His concrete, called *Béton Aggloméré*, consists of about 180 parts of sand, 44 of lime produced by slaking, 33 of Portland cement, and 20 of water, combined by a process of two main operations: I. A complete consolidation of the materials with little water; and II., the steady but not violent compression of the consolidation in moulds. The cement is mixed with the sand and lime, and sprinkled whilst mixing with a *little* water. This mixture is thrown into a machine,

formed like an endless screw enclosed in a cylinder, at the rate of two shovelfuls followed by about a quart of water, until the cylinder is full. The screw, turned by two men, delivers the mixture through a series of holes in the bottom of the cylinder; but on a large scale, a machine is used of 10 to 15 horse power. This mixture, after its delivery from the machine, is put by degrees into moulds, and each layer is rammed in by workmen. In reply to questions put to the inventor by the Committee of the Institute already mentioned, he stated that chalk lime was not sufficiently hydraulic for the purpose: that ground lime as delivered had always *core* in it, and therefore had to be slaked with one fifth of its bulk of water for forty-eight hours before employment; such mixture was equal in effect to two of common ground lime: that when very hard mortar was required it was necessary to use less water and more sand than usually adopted: that water evaporated from mortar as usually made, leaves it full of minute holes, and that the more water, the less is the crystallisation: that in the proportions above given, if cement be used as a twentieth part, it requires to be twice passed through the large machine, but if used as a thirtieth part, only once: that he found by experience that the purer the lime the quicker was the crystallisation; and that, although pure hydrate of lime will take carbonic acid, silicate of lime and alumina will not take it, because silicic acid took the place which carbonic acid did with the pure lime; and frankly admitted that his first experiments in 1855, in marine works, had not entirely succeeded, but claimed perfect success for those at Marseilles since 1859, and for those now (1864) executing in Paris and elsewhere.

1862*g*. The resistance of *béton* and *concrete* should never be regarded as being superior to those given for limes, if the superstructure be commenced upon them immediately. In both cases the resistances are found to increase with comparative rapidity during the first six or seven months.

1863. Among the CEMENTS used in England, *Parker's*, also called *Roman* cement (1796), is manufactured principally from stone found in the Isle of Sheppey, and at Harwich, being *septaria* from the London clay, and properly classed among the limestones indigenous to this country. It consists of ovate or flattish masses of argillaceous limestone arranged in nearly horizontal layers, chiefly found imbedded in the clay. The substance being coated with a calcareous spar or sulphate of barytes, forms the basis of the cement. That now in use we do not think at all equal to the material originally employed. About 1810–15 it was possible to use it in the depth of winter; which, we apprehend, would be a hazardous thing to do with the cement at present made. Whether the inferiority arises from adulteration, bad manufacture, or the material being worse, we cannot pretend to say; we, however, do not believe that it arises from the badness of the raw material. If this cement be of extremely good quality, 2 parts of sand to 1 of the cement may be used. The cement itself is a fine impalpable powder; yet when wetted it becomes coarse, and, unless mixed with great care, it will not take a good surface. When mixed with the sand and water, it sets very rapidly; it is necessary, therefore, to avoid mixing much at a time, or a portion will be lost. The colour of this cement, when finished, is an unpleasant dark brown, and the surface requires frequent colouring. The great value of Parker's cement is its being impervious to water almost the moment it is used; hence it becomes highly serviceable on the backs of arches under streets, for the lining of cisterns, and for carrying up in it, or coating with it, damp walls on basement stories. It will not resist fire so well; and it should therefore never be employed for setting grates, ovens, coppers, or furnaces.

1864. *Athinson's* cement is a good material, preferable in colour to the last named, but, as we think, inferior in quality. It takes a much longer time to set than Parker's cement, than which it absorbs more moisture. It answers well enough in dry situations. Vicat formed a factitious Roman cement; but its efficacy was doubtful, though it had, for want of a better substitute, been much employed at Paris.

1864*a*. *Portland cement*, the latest (about 1843) of all these cements, is made from limestone and clay. The mud of the river Medway, corresponding to the argillo-calcareous stone of Roman cement, is mixed with chalk and ashes from former makings, and calcined at a heat amounting almost to that of vitrification. A larger quantity of sand may be mixed with it than with Roman cement, to which it is superior in colour and hardness of setting. The heaviest, considered the best in quality, weighs 110 lbs. per striked bushel.

1864*b*. The distinguishing peculiarities which should render *Portland* cement a permanent substitute for *Roman* cement, have been explained by a London manufacturer of both materials (*Builder*, 1863, p. 761). It may be condensed into the statement:—That the stone from which Roman cement is made, though composed of lime and the silicate of alumina, yet the proportion of the latter preponderates to such an extent as to prevent a perfect amalgamation of the ingredients in burning. The result is a cement loose in its texture, because containing inert foreign matter, which is retentive of moisture, and consequently attackable by frost and vegetable growth. In Portland cement the case is otherwise. The dose of lime to clay is in the ascertained correct proportion of two to one, and with this condition there is the power thoroughly to combine the ingredients by burning, and thus to give a density and compactness to the product, which in enabling it to resist water, frost,

and other decomposing agencies, are the elements of its durability and of its superiority to the natural cements. Carelessness, or want of proper knowledge in its manufacture; an improper mixture of the ingredients; an imperfect calcination; its bad manipulation; and unfair handling when used as a cement, are all likely to result in disastrous effects on being used. When employed as a mortar or as a concrete, it has seldom been known to fail.

1864*c*. It is usual for the manufacturer to grind the cement after burning it. It is then placed in well-closed casks which should not exceed 6 cwt. each, when the cement may be preserved for some time; but contact with the atmosphere rapidly deteriorates its quality, as it absorbs humidity and carbonic acid from it, and thus becomes useless. It should be ground very fine. For the sieve in sifting it, the French engineers require 185 meshes to the square of 4 inches on a side. One-third of the volume of the cement for the quantity of water is the best proportion, and the more that the cement is beaten up, the harder it becomes. The best cement will harden in about five or six minutes, and under water in about an hour: when mixed with sand it takes a little longer. When mixed with sea-water, and used in sea-water with a large quantity of sand, it may take even twenty-four hours before setting.

1864*d*. The resistance to rupture of pure cement after 20 days' exposure to the air, is about 54 lbs. per inch square; if sand be added in the proportion of $\frac{1}{2}$ to 1 of cement, it falls to 37 lbs.; and if it be in equal proportions, it falls to 27 lbs. The permanent load in any large works should never be more than one-sixth of that required to produce rupture: and if small materials be employed, only one-fifteenth should be calculated upon. The strength of Portland cement has been tested for drainage works by John Grant, as described at the Institution of Civil Engineers, December 1863, giving it as 500 lbs. upon an area of $1\frac{1}{2}$ inches square, equal to $2\frac{1}{4}$ square inches.

1865. *Hamelin's mastic* cement, though patented of late years, is an invention of P. Loriot, a century old; the medium for mixing the pounded brick-dust, limestone and sand, is oil instead of water. It is much more difficult to use than the other cements, and requires great experience and care. A coat of it should never exceed one quarter of an inch in thickness; hence it is totally unfit for working mouldings in the solid. In the metropolis it is generally used in a very thin coat over a rough coat of Roman cement, in which case it is rarely more than an eighth of an inch thick. Thus used, it not only presents a beautiful surface, but is extremely durable, but it requires to be constantly painted to resupply the oil that has evaporated, or been taken up by the atmosphere.

1866. *Keene's* cement is obtained by soaking plaster in alum water after a first calcination: it is then kiln-burnt a second time and ground. It is in reality only a plaster, and is capable of being worked to a very hard and beautiful surface. *Martin's* patent fireproof and ornamental cement is a plaster of somewhat similar make, and equally good-looking. It is manufactured in three qualities, coarse, fine, and superfine. It is said to be used with greater facility by workmen than any other cement yet produced, requiring only about an hour to set, which is less by one-half the time of other cements. It appears to be chiefly prepared at Derby. *Parian* cement (Keating's patent) is also composed of gypsum, but mixed with borax (borate of soda) in powder, and the mixture calcined and ground. A fine quality produces a hard scagliola imitation of marble. When applied to old brick or plastered work, as in repairs, these cements may be papered, or painted upon, in about 18 to 24 hours after execution. But on new work time must be given for any efflorescence to disengage itself.

1866*a*. *John's patent permanent stucco wash, stucco cement, and stucco paint*, were introduced about 1843. As a paint it is cheap, durable, agreeable in colour, and finishes without a gloss. It gives out no deleterious exhalations or odour in drying, and it is stated that as the oil cannot evaporate (?), but is held in intimate and indissoluble union with the other materials, there can be no decay, an objection to which oil mastic is so liable. It requires no driers or turpentine, and is applicable both for outside and inside work. The cement, which is stated not to deteriorate with age, is packed in casks, and requires to be mixed with 3 parts of good, sharp, clean sand to make a stucco, its application for which is the same as for any other stucco. It adheres well to glass, iron, slate and tiles in roofing, wood, old plaster, or Roman cement. When set it is hard, and impervious to wet and damp. One coat of its own paint, which it will take after twenty-four hours, is sufficient. Mouldings may be run in it, and castings made.

1866*b*. A cement which will withstand a moist climate, is stated to be composed of one bushel of lime with 15 gallons of water and half a bushel of fine gravel sand, mixed with $3\frac{1}{2}$ lbs. of copperas dissolved in hot water, and kept stirred while being incorporated and in use. Sufficient should be made for the day during which it is to be used, as the colour is not easily matched.

1866*c*. GYPSUM, better known as *Plaster of Paris*, is a sulphate of lime. It is found at Alston, in Cumberland; at Shotover Hill, Oxfordshire; at Orston, near Grantham; in Nottinghamshire, in Derbyshire, and in Cheshire; in France, in the neighbourhood of Paris, chiefly at Montmartre; and in the departments of the Saone, Loire, of the Rhone,

and of many others; and in Tuscany, Savoy, Spain and Switzerland; in some parts of the British Colonies of North America, wherefrom it is exported principally to the United States. The stone is broken into small blocks, and burnt in a walled space with openings in the tiled roof to let out the steam. After its water of crystallization is driven off, it becomes pulverulent and like flour. On fresh water being added, it combines with the normal quantity of water, and reassumes the form of a hydrate, recovering its original density and strength to a very great degree. A heat of about 200° centigrade is sufficient. The London manufacturers adopt a kind of oven for burning the stone, which prevents the smoke from injuring the plaster. In France it has been proposed to throw a jet of steam heated above 400° Fahr. over the stone, which is broken very much smaller than usual: this jet takes up all the water present, and leaves the plaster in the state of a pure anhydrous sulphate of lime. The plaster obtained from Paris is considered the best of all in quality, probably arising from the fact that the stone is the hardest. Gypsum swells in setting in contradistinction to the cements, which generally shrink. The specific gravity of pure gypsum may be taken at 2·322; and its constituent parts to be sulphuric acid 46, lime 32, and water 21. (See Glossary, s. v.)

1867. The best *bituminous cements* are obtained from the natural *asphalte*, which is found in large quantities on the shores of the Dead Sea; in Albania; in Trinidad; at Lobsann, and Bekelbronn, in the department of the Bas Rhin; in the department of the Puy de Dôme; at Gaugeac in that of the Landes, &c. The asphalte which is found in inexhaustible quantities at Pyrimont Seyssel, in the Jura Mountains, in the department of the Aire in France, was introduced into England about 1838, under Claridge's patent. The principal ingredient in its composition is a bituminous limestone, of a rich brown colour. After it has been reduced to a fine powder, a certain portion of grit is mixed with it; it is then placed in cauldrons heated by strong fires with a sufficient quantity of *mineral tar* to prevent the asphalte from calcining. The whole mass is thoroughly incorporated and reduced to a mastic, in which state it is run into moulds to form blocks, each 1 foot 6 inches square, 6 inches in depth, and weighing 125 lbs.

1867*a*. The mastic is of three qualities, fine, gritted, and coarse gritted. The first, being without any admixture of grit, is used for magazine floors, and as a cement for making, in special cases, very close joints in brickwork. II. The fine gritted is used for covering terraces, roofs and arches, lining of tanks, and as a cement for brickwork, and for running the joints of stones. III. The coarse gritted is used for paving and flooring, and where great strength of work is desirable, such as gun-shed floors, tun-room floors, and margins of stable floors; while in gateways for heavy carriage traffic, small pieces of granite chippings are introduced. These mastics, and more particularly the first two, being ductile and readily yielding to any change that may take place on the surfaces upon which they are laid, require a proper foundation to be prepared.

1867*b*. When required for use, an iron cauldron having been prepared, 2 lbs. of mineral tar are put in, and then 56 lbs. of asphalte broken into pieces of not more than 1 lb. in weight. These are mixed together until the asphalte becomes soft. After a quarter of an hour the stirring is repeated, and another 56 lbs. of asphalte added, and so on until a proportion of 112 lbs. of asphalte to each 1 lb. of tar, under ordinary circumstances, fills the cauldron and the whole is thoroughly melted. When fit for use the asphalte will emit jets of light smoke, and freely drop from the stirrer.

1867*c*. It will be well to note that it is stated asphalte never flames, but merely passes into a state of fusion. At the fire at Hamburg in 1842, it was remarked that when asphalted roofs fell in, "the asphalte, in which a sort of rubble is mixed up, was found to have resisted the effects of the heat, and, like a mass of dirt, served rather to smother the flames than to give them increased vitality." A like result is recorded of a fire that took place at the Bazaar Bordelais, at Bordeaux, in 1835; of another in Stangate, London, in 1855; and experiments were made by order of the authorities of the British Museum before this material was allowed to be applied to the snow gutters of the dome of the new Reading Room and other roofs, with a satisfactory result. Notice is not generally taken of the fact that if in works, asphalte or tar be used in places where it may be affected by heat, a smell arises which is very prejudicial to the comfort of the occupiers of the building.

1867*d*. The term asphalte has also been given to several compositions formed by the admixture of chalk, lime, gas tar, and other substances for cheapness. The *coal tars*, and vegetable pitch, although not so good as the bitumens, are fairly good substitutes in many cases, as in coating vaults, or walls exposed to the dampness of earth. The proportions in which to mix powdered calcareous stone must be regulated by practice, as also the heat, that the stone be not converted into quicklime, perhaps from 6 to 7 of the pitch in volume to 1 of limestone will suffice; and it is recommended to use these in greater thickness than the asphalte, being about half an inch for the latter material.

SECT. XII.

GLASS.

1868. Glass is a combination of silex with fixed alkali, generally soda. The mixture when calcined receives the name of *frit*, which after the removal of all its impurities, is conveyed to the furnace and melted in large pots or crucibles till the whole mass becomes beautifully clear, and the dross rises to the top. After being formed into the figures required, it is annealed or tempered by being placed in an appropriate furnace. The fineness depends on the purity and proportion of the ingredients. An extremely fine crystal glass is obtained from 16 parts of quartz, 8 of pure potash, 6 of calcined borax, 3 of flake white, and 1 of nitre. The specific gravity of glass is about 2600; of French plates, 2840; of English flint glass, 3320. Glass is extremely elastic, and less dilatable by heat than metallic substances.

1868*a*. Four pieces of the common sort of glass being cut from one strip, each piece was 5 inches wide, 6 inches long, and 4 inches thick. In the trial of strength they were calculated out at a standard size, and gave 17,208 lbs., 15,435 lbs., 14,931 lbs., and 11,385 lbs.; the mean being 14,931 lbs. This great difference is the more singular from the circumstance of all the pieces being cut from the same plate. The weight of the glass at a size of 9·0 x 4·5 x 3, all in inches, would be 11·12 lbs. *Sheet* glass is stated to be stronger than *plate* or *crown* glass, but less flexible. The compressive strength of glass is about $1\frac{2}{4}$ tons per square inch. The resistance of glass to a crushing force is about 12 times its resistance to extension.

1869. Pliny gives the following account of the discovery of manufacturing glass, which was well known in Aristotle's time, 350 B.C. "A merchant vessel, laden with nitre or fossil alkali, being driven on the coast of Palestine, near the river Belus, the crew accidentally supported the kettles on which they dried their provisions on pieces of the fossil alkali; the sand about it was vitrified by its union with the alkali, and produced glass." Though, according to Bede, artificers skilled in making glass were brought into England in 674, glass windows were not generally used here till 1180, and were for a considerable time esteemed marks of great magnificence.

1870. The manufacture of window glass during the last thirty years has undergone entire alteration, especially since the abolition of the excise duty in 1845. There are now three special kinds of glass used for glazing purposes, and several varieties of them:

1870*a*. I. *Crown* glass, which is blown into large globes and opened out into circular flat tables. II. *Sheet* glass, which is blown into long cylinders or *muffs*; then split down and flattened. III. *Plate* glass, which is either cast on iron tables for large purposes, and polished; or for smaller squares, blown into a cylinder and polished.

1871. *Crown glass*, the commonest window glass, differs from flint glass in its containing no lead or any metallic oxide except manganese, and sometimes oxide of cobalt, in minute portions, for correcting the colour, and not as a flux. It is compounded of sand, alkali, either potash or soda, the vegetable ashes that contain the alkali, and generally a small portion of lime. To facilitate fusion, a small dose of arsenic is frequently added. Zaffre or oxide of cobalt, in the proportion of 1 ounce for 1000 pounds, is added to correct the colour; but when the sand, alkali, and lime are very fine, and no other ingredients are used, zaffre is not required. Its manufacture is conducted differently from that of flint-glass articles, the object being to produce a large flat thin plate, which is afterwards by the glazier's diamond cut into the requisite shape. It is blown in circular plates, varying from 3 feet 6 inches to 4 and 5 feet diameter: the process is as follows:—The workman, having a sufficient mass of melted metal on his blowpipe, rolls it on an iron plate, and then, swinging it backwards and forwards, causes it by its own gravity to form into a globe, which is made and brought to the required thinness by blowing with a fan of breath, which persons accustomed to the work know how to manage. The hollow globe is then opened by holding it to the fire, which expanding the air confined within it (the hole of the blowpipe being stopped), bursts it at the weakest part, and while still soft it is opened out into a flat plate by centrifugal force; and being disengaged from the rod, a thick knob is left in its centre. It is then placed in a furnace, or in a certain part of the furnace to undergo the process of annealing. When the table is cut for use, the centre part in which the knob remains is called *knob-glass*, and is used only for the very commonest purposes. Tables are now made of such a size that squares may be procured 38 inches by 24 inches as extra sizes.

1871*a*. The qualities of crown glass in common use are called best, seconds, thirds, and fourths or coarse; with two still coarser. The last is of a very green hue, and only used for inferior buildings. They were sold by the *crate*, at the same price, the difference being made up by varying the number of the tables contained in it. Thus a crate of best crown glass contained twelve tables; of seconds, a crate contained fifteen; and of thirds, eighteen tables. They are now sold (by Messrs. Hartley) in crates of eighteen tables of the usual

thickness averaging 53 inches ; and in crates of twelve tables of extra thickness averaging 52 inches. Flattened slabs of the same qualities are sold in crates of thirty-six slabs of the usual thickness, and in crates of twenty-four slabs of extra thickness, each averaging 24 inches, 22¾ inches, and 21½ inches. The flattened slab is also made as 'obscured' glass. The sizes of both qualities vary from 'quarries'; under 9 by 7; up to, above 4½ feet, and not above 5 feet superficial. Taking the usual thickness of

Best	as	00	extra thickness	150
Seconds	,,	90	,,	135
Thirds	,,	65	,,	110
Fourths	,,	50	,,	85
CC and CCC	,,	43 and 40	,,	63 and 50 (Adcock).

1872. *Sheet* glass has been manufactured in England with great improvements since 1832 to 1838 by Messrs. Chance and Hartley, with the co-operation of M. Bontemps, of Paris. Though inferior in colour, this glass is in other points generally superior to that of the foreign manufacture. It is composed of the same or similar materials to the above, in well ascertained proportions, and with sulphate of soda to give whiteness. In the manufacture of sheet glass a sufficient quantity of the metal is collected at the extremity of a blow-pipe, and then lengthened by swinging and blowing, till it acquires the form of a hollow cylinder, which is then detached, the neck being cut off with a thread of hot glass; and one side of the cylinder is cut down lengthwise with a heated iron or diamond. It is then taken to the flattening kiln, where the heat causes it gradually to open nearly flat on a bed called *largre*, where it is rubbed down by means of a block of wood called a *polissoir*, and then becomes *flattened sheet*. After this operation it is placed in the annealing oven to cool gradually. This operation is referred to by the monk Theophilus, who wrote about the end of the twelfth century or later, as in use in his time. The method was also employed by the Venetians especially for coloured glass, as it secured uniformity. But on the cessation for its demand, the employment of the cylinders was entirely superseded in France, England, and the North of Germany, for the rotary principle.

1872*a*. The great advantage of *sheet* glass is that of affording plates of larger dimensions, and not only of avoiding the waste arising from the circular form of the *crown* tables, but also from the knob or bull's eye in the centre. The surface, however, is much less brilliant than that of crown glass, and is more wavy and undulated. Messrs. Chance, in 1838, introduced a thicker quality of sheet glass, which was at the same time of a better surface, and since then its use has become general.

1872*b*. In 1840 the same firm introduced a new variety of window glass under the name of *patent plate*, which they obtained from a thick sheet glass by a new process of grinding and polishing. They made plates of several degrees of thickness, and of sizes containing from 8 to 12 feet superficial. The surface of the glass obtained by this process, though not perfectly true, is very nearly so; and in brilliancy it is unsurpassed even by cast plate. For glazing sashes it has nearly superseded crown and sheet glass. But for squares of somewhat large dimensions, it may be calculated whether *plate* glass will not be as cheap or cheaper.

1872*c*. As will be perceived by the above short account of the mode of manufacture of *sheet* glass, its size is almost only limited by the strength of the workman. It is chiefly sold in crates as manufactured, in sheets of not less in width than 28 inches, and not less than 9 feet superficial area; with a limit of width not exceeding 45 inches, and a limit of length not exceeding 75 inches; but these extremes of width and length cannot be combined in the same sheet. Thus in glass of 15 ounces to the foot, the dimensions 55 by 36 inches, or 12½ feet in area, is the largest plate. In 21 ounce glass, 75 by 45 inches, or 18 feet area: in 26 ounce glass, 75 by 45 inches, or 17 feet area: in 32 ounce glass, 65 by 44 inches, or 15 feet area: in 36 ounce glass, 60 by 42 inches, or 12½ feet area: and in 42 ounce glass, 55 by 38 inches, or 11 feet area. The four first weights are made in qualities of best, seconds, thirds, and fourths; and the two first have two qualities A and B for pictures. There is no fourth quality to the two last named weights. All these sorts are cut into squares for glazing.

1872*d*. *Fluted sheet* glass of 15 ounce and 21 ounce is usually supplied in crates not above 43 inches long; but it is made up to 50 inches in length. *Obscured sheet glass* is supplied in all substances.

1873. *Patent plate* glass, already described (*par.* 1872*b*.) is made in three qualities, B or best, C or second, and CC or third, quality. Each of these are of four kinds, known as No. 1, which is of an average thickness of $\frac{1}{18}$th of an inch, and is of an average weight of 13 ounces to the foot; No. 2 is $\frac{1}{12}$th thick, and 17 ounces; No. 3 is $\frac{1}{10}$th, and 21 ounces; and No. 4 is $\frac{1}{9}$th, or 24 ounces to the foot. No. 4 B is thus the very best quality made; the prices for the size required vary but about one or two pennies per foot in each kind; and from threepence to sevenpence in each quality. They are manufactured in sizes from 4 to 13 feet in area, not above 50 inches long, or 36 inches wide.

1874. *German sheet*, or *Belgian sheet* glass, as it is sometimes called, was formerly in much demand in England; and is still used for cheapness. Its appearance is more wavy

and speckled than the English manufacture. *Crystal white sheet* glass, for glazing pictures and prints, is imported from Florence in cases of 100, 200 and 300 feet, in first, second and third qualities, and appears superior to other glass in whiteness, but it has the defect of 'sweating.' Similar named glass for such purposes made by Messrs. Chance, appears to us to be very green, and therefore detrimental to prints and pictures; but on the other hand it does not sweat.

1875. *Plate* glass is so called from its being cast in large sheets or plates. Its constituent parts are white sand, cleansed with purified pearl-ashes, and borax. If the metal should appear yellow, it is rendered pellucid by the addition, in equal small quantities, of manganese and arsenic. It is cast on a large horizontal table, and all excrescences are pressed out by passing a large roller over the metal. To polish it, it is laid on a large horizontal block of freestone, perfectly smooth, and then a smaller piece of glass, fastened to a plank of wood, is passed over the other till it has received a due degree of polish. For the purpose of facilitating the process, water and sand are used, as in the polishing of marble; and lastly, Tripoli, smalt, emery, and putty, to give it lustre; but to afford the finishing polish the powder of smalt is used. Except in the very largest plates, the workmen polish their glass by means of a plank having four wooden handles to move it, and to this plank a plate of glass is cemented.

1876. In the GLOSSARY, s. v. Glass, plate, will be found the tariff of the Thames Plate Glass Company in London, for unsilvered plates for mirrors, of which there are two qualities, second and best. The Paris factory supplied in 1865 two looking glasses for the Mayor's room in the Town Hall at Liverpool, each 15 feet by 10 feet. *Polished plate* glass is manufactured for general glazing purposes up to about 80 feet superficial, of two qualities, usual and best. The usual thickness is a quarter of an inch: higher prices are charged for glass selected to be cut above $\frac{3}{16}$ ths., $\frac{5}{16}$ ths., and $\frac{3}{8}$ ths. thick; while for above $\frac{3}{8}$ths. thick, special prices are charged. The best quality is declared to be of the very purest colour, free from specks, and not subject to dampness or sweating.

1877. *Rough plate* glass, cast, is used for roofing, in skylights, windows, &c., in plates from not above 20 inches long, to above 120 inches long, in thicknesses of $\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{2}$, $\frac{3}{4}$, inch, $1\frac{1}{4}$, and $1\frac{1}{2}$ inch; but these thicknesses have certain limited lengths. The widths are the same as for plate glass. This glass is not ground or polished, but rough from the table, and showing the table marks on its underside.

1878. The *patent rough plate* glass, which is also cast, must not be confounded with the above. It is extensively used for ridge and furrow roofs, conservatories, manufactories, skylights, workshops, and other places where "obscured" glass is required to intercept the vision without diminishing the light. Blinds are unnecessary, and when it is used in greenhouses, no scorching of the plants occurs. The quality known as $\frac{1}{8}$th. of an inch thick, weighing about 2 lbs, or 32 ounces to the foot, is usually provided for these purposes, and is no more, weight for weight, than common crown glass. When greater strength is required, $\frac{3}{16}$ths. and $\frac{1}{4}$ inch thick is said to be cheaper and of a finer quality than the common rough plate; but we demur to this statement, as of late years the manufacture appears to have decreased in strength from the greater use of sand for cheapness; in moveable window frames in warehouses, a lamentable quantity of broken squares is to be seen almost before the floors are occupied.

1878*a*. This glass is made of two kinds; I. Plain, which is merely marked by the fine grain of the casting table, and is that above noticed; and II. Fluted, of two sorts, No. 1, large pattern, having $3\frac{1}{2}$ flutes to the inch; and No. 2, small pattern, having 12 flutes to the inch. Both the plain and the fluted kinds are made $\frac{1}{8}$th. $\frac{3}{16}$ths. $\frac{1}{4}$, $\frac{3}{8}$ths. and $\frac{1}{2}$ inch in thickness. The width is about 3 feet, and the length usually not above 70 inches; but 75, 90, and 100 inches long, are also made. When a clear glass and much non-transparency are required, No. 2 fluted is the best.

1879. *Quarry* glass is also made in this material; No. 1 being 6 inches by $4\frac{1}{8}$th inches from point to point; No 2 being 3 inches by $2\frac{1}{16}$ inch. *A stained ornamented patent quarry rough plate* is made for churches, chapels, schools, &c. *A patent diamond rough plate* glass is also manufactured. A patent rough plate, and sheet, *perforated* glass, polished or unpolished, for ventilation, can be obtained in sizes, which require consideration in arranging, on account of the length of the slits or perforations. It is usually made in columns $1\frac{1}{2}$ inches wide, and $2\frac{1}{2}$ inches apart; the space between each slit vertically being $1\frac{1}{2}$ inches. Larger sizes, or the columns wider apart, can be obtained from various manufacturers, or to order.

1880. Many other applications of glass will be noticed in the ensuing chapter. We must here state that the details given in this section are founded upon the price list issued by Messrs. Hartley, of Sunderland, and would state our regret that the manufacturers have not deemed it advisable for their own interests, to provide some place in London, and in other large towns, where the architect can call and compare the qualities of glass supplied under his specification with standards there placed. It was comparatively easy in former years to judge of good glass; now it is almost impossible.

CHAP. III.

USE OF MATERIALS, OR PRACTICAL BUILDING.

Sect. I.

FOUNDATIONS AND DRAINS.

1881. In the previous chapter, we have enumerated the principal materials used in building; we shall now proceed to show how those materials may be most advantageously employed; but we shall not, in the various branches of the practice, again touch on the materials themselves, which have been, we conceive, already sufficiently described. But previous to entering upon the different branches of practical building, we think it right to submit to the reader a few observations on that most important of all considerations—a due regard to the security of the foundations on which a building is to stand, as a preliminary to the works of the bricklayer and mason, as the case may be. No advance or improvement has been made in this branch of architecture, as a science, since the time of the ancients. The advice of Vitruvius may still be followed with safety. In England, the recent introduction of concrete (no modern invention) has superseded the use of wood under walls in the earth; and piles are now quite exploded, except for the piers of bridges and other situations in which they can constantly be kept wet.

1882. The best soils for receiving the foundations of a building are rock, gravel, or close-pressed strong sandy earth; "but," says L. B. Alberti, "we must never trust too hastily to any ground, though it may resist the pick-axe, for it may be in a plain, and be infirm, the consequence of which might be the ruin of the whole work. I have seen a tower at Mestre, a place belonging to the Venetians, which, in a few years after it was built, made its way through the ground it stood upon, which, as the fact evinced, was a loose weak soil, and buried itself in earth up to the very battlements. For this reason, they are very much to be blamed who, not being provided by nature with a soil fit to support the weight of an edifice, and lighting upon the ruins or remains of some old structure, do not take the pains to examine the goodness of the foundation, but inconsiderately raise great piles of building upon it, and out of the avarice of saving a little expense, throw away all the money they lay out in the work. It is, therefore, excellent advice, the first thing you do, to dig *wells*, for several reasons, and especially in order to get acquainted with the strata of the earth, whether sound enough to bear the superstructure, or likely to give way." It is important, previous to laying the foundations, to drain them completely, if possible, not only from the rain and other water that would lie about, but from the land water which is, as it were, pent up in the surrounding soil. In soft, loose, and boggy ground, the use of concrete will be found very great; and in these soils, moreover, the width and depth it should be thrown in, should, as well as the lower courses of the foundation, be proportioned inversely to the badness of the soil. Clay of the plastic kind is a bad foundation, on account of the continual changes, from heat and moisture, to which it is subject, and which often cause it so to expand and contract as to produce very alarming settlements in a building. The best remedy against this inconvenience is to tie the walls together by the means of chain plates, buried in the centre of the footings, and on the top of the landings that rest on the concrete; these plates to be, of course, connected at the returning angles, so as to encompass the whole building. In these cases, the clay must be excavated to make room for the concrete. This will be found an effectual remedy in clay soils.

1883. If the soil be a sound gravel, it will want little more than ramming with heavy rammers; and if the building be not very heavy, not even that.

1884. Where vaults and cellars are practised, the whole of the soil must, of course, be excavated; but where they are not required, trenches are dug to receive the walls, which, in both cases, must be proportioned in strength to the weight of the intended superstructure and its height. In general terms, we may direct the depth of foundations to be a sixth part of the height of the building, and the thickness of the walls twice that of those that are raised upon them. Care must be taken that that which is to receive the footings of the walls be equable; otherwise, where external and internal walls are connected together, the former, being the heaviest, may settle more than the latter, thereby causing fractures, which, though not, perhaps, dangerous, are extremely disagreeable in appearance. The lower courses, which are called the footings of the wall, are often laid dry; and, perhaps, at all events, a sparing use of mortar in a spot loaded with the greatest pressure should be preferred. If the footings be of stone, very particular attention should be bestowed on

placing the stone in the courses in the same direction or bed as it lay in the quarry, to prevent its splitting.

1885. In foundations where, from columns or small piers pressing upon particular parts, there would be a liability, from uneven bearing, to partial failure, it has been the practice, from a very early period, to turn inverted arches (see *fig.* 615.) to catch on their springing the weight to be provided against, by which means such weight is equally distributed throughout the length of the foundation. "Standing thus," says our master Alberti, "they (the columns or weights) will be less apt to force their way into the earth in any one place, the weight being counterpoised and thrown equally on both sides on the props of the arches. And how apt columns are to drive into the ground, by means of the great pressure of the weight laid on them, is manifest from that corner of the noble temple of Vespasian that stands to the north-west; for, being desirous to leave the public way, which was interrupted by that angle, a free and open passage underneath, they broke the area of their platform, and turned an arch against the wall, leaving that corner as a sort of pilaster on the other side of the passage, and fortifying it as well as possible with stout work, and with the assistance of a buttress. Yet this, at last, by the vast weight of so great a building, and the giving way of the earth, became ruinous."

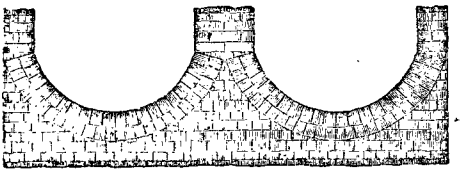

Fig. 615.

1885*a*. A method of forming foundations has lately come into vogue for bridges and other hydraulic constructions by the use of *cylinders* or other shaped air-tight cases. In India the system of founding large masses of masonry on cylindrical piers built in the interior of wooden curbs, has prevailed for a long period. The method of constructing the piers is the same as that used in England in sinking the steining for ordinary wells; and when sunk the interior is filled up with concrete or rubble masonry. Some of the iron bridges lately erected over the River Thames and elsewhere have been placed on foundations formed by cast iron cylinders filled in with concrete. Further details must be sought in works devoted to *Civil Engineering*, as the system will seldom be applicable in strictly architectural constructions.

1886. It is most important, when the walls are raised on the foundations, and brought up a little above the level of the earth, to take care that the earth, most especially if moist, should not lie against them; for if walls, before they are dry and settled, imbibe moisture, they rarely ever part with it, and thence gradually impart rot to the timbers throughout the house. In all buildings, it is an object to have a second thin wall outside the basement walls, so as to leave between it and them a cavity for the circulation of the air, such cavity being technically called an *air-drain*. This is in all cases desirable, but in moist and loose soils it is essentially necessary for the durability of the building, as well as for the health of those who are to dwell in it.

1886*a*. It is important that the *air-drain* or *dry area* should commence at least as low as the foundations of the building; in very wet situations it should be provided with pipes connected with the main drains of the building, to carry off the superabundant moisture. Even when provided, the usual precautions to prevent damp arising in the main walls must not be neglected. The *air-drain*, which should never be less than 8 inches wide, or more if possible, is commonly covered with a half-brick arch, or with stone, slate, or tile, *below* the surface of the ground. This entirely does away with the benefit anticipated by its formation, because the surface drainage descends and injures the main wall even when cemented above the covering; this should be placed some inches *above* ground. It also often degenerates into a hole for dirt and vermin. The best arrangement is to make a *dry area*, or a space wide enough to be easily cleared out, and to which a cat or dog can have access, and to cover it with stone with moveable gratings at convenient distances; the expense will not be much greater, while the result will be very effective. The most secure arrangement, however, is to form an open area all round the building. The want of such a precaution in the houses in the suburbs of London renders a large majority of those having basements nearly uninhabitable from the disagreeable consequences of damp walls.

1886*b*. *Damp courses.* This simple provision to prevent wet which is likely to get into walls, from rising in them by capillary attraction, is too often neglected, especially in cheap work, for the present saving of a pound or two; but at the ultimate expenditure of many pounds. The simplest plan has generally been to work three courses of the brickwork above the footings and below the ground floor, in cement. Messrs. Smith of Darnick state that a coating of cement, done in a very substantial manner, did not appear to have the smallest effect, as the wall was as damp above it as below. For *small* cottages they found an effective plan was to build all the parts of the wall underground quite *dry*, and

not to use any mortar until clear of the earth. This left the walls quite dry above. The next method is to bed a course of sound whole slate slabs, a quarter of an inch thick, in cement. When the soil is very damp, two or even three courses of ordinary slates may be laid in and well bonded, not only in the main walls, but in all cross partitions and dwarf walls. For some reason, probably that of the slates and cement having separated or crushed with the weight of the walls, allowing the damp to pass through, this method has fallen into disuse. As Portland cement will adhere to slate, probably in solid works, if used instead of Roman cement, the result would be more satisfactory.

1886*c*. Sheet zinc bedded in loam has been found to decay. In extensive works, fine-gritted asphalte, applied in a hot state, is introduced as a layer, about half an inch in thickness. This material is stated, in the Appendix to the *Report of the Fine Arts Commissioners*, to have kept out the effects of damp, which would have shown themselves, as the foundations of the building referred to were always in water about 20 inches below the level of the ground floor. The brickwork should be dry and protected from rain during the operation to prevent the asphalte becoming honeycombed. In buildings already erected, the walls can be underpinned to introduce the material. At the New Palace at Westminster the joints are only half filled with mortar, the asphalte filling the remainder when poured over the bricks. The bricks for the next course, having been heated at a coke fire, were placed on the asphalte in its fluid state, and the joints half flushed up. The outer courses, however, should be first laid for short distances, that they may set before the middle is filled in. In rubble masonry, it will be necessary to fill up all inequalities on the surface with fine concrete; when this has set sufficiently, the asphalte is to be laid as described for brickwork. Gas tar mixed with lime is said to be impervious to wet.

1886*d*. Two centuries ago, thin sheet lead was laid on the top course of a wall to prevent damp coming down it from the gutters; of late years, a layer of 4 lb. milled lead has been proposed to prevent it rising; no doubt the best and most efficacious remedy, but the cost would be greater than usually allowed. But the best invention, having price also in its favour, is the *damp-proof course*, formed of brown stoneware, perforated through

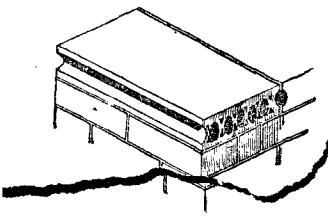

Fig. 615*a*.

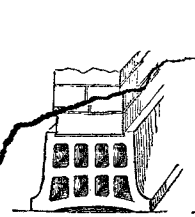

Fig. 615*b*.

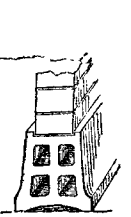

Fig. 615

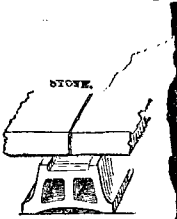

Fig. 615*d*.

out its entire width, with a half air space, which remains open after the mortar beds are laid, on each side of the slab. In an executed work, a course of bricks can be cut out and the stoneware be inserted. This is one of the many building inventions of Mr. John Taylor, junior. *Fig.* 615*a*. shows one for an 18-inch wall; other sizes as well as angle blocks are provided. Each foot superficial is stated to be equal to the support of 25 tons or 600 feet of vertical brickwork. Jennings has patented earthenware *sleeper blocks*, "non-conductors of damp and a cheap substitute for brick sleeper walls;" they are also useful for carrying stone paving: *Figs.* 615*b*., 615*c*., and 615*d*. describe themselves.

1886*e*. Precautions are also necessary to prevent the access of damp from the surface of the ground next the outside face of the wall. If the dry area be carried up sufficiently high, the two measures are effected at once. If not, a facing of stone or slate is the best remedy. The former need not be very thick; but it is well for both to be from two to three feet high. If a small interval be left between this facing slab and the outside surface of the wall, it will provide for a circulation of air being kept up in the space. By this provision, although the facing slabs may be temporarily damped by rain, they will soon be again dried without having communicated the damp to the body of the wall.

1886*f*. A preventive against the effects of damp in the inside of the building is to cover the whole area within the walls with a layer of *concrete*, about 4 to 6 inches thick (from 6 to 9 inches is better); but as concrete is of a honey-comb character even when fixed or set, being full of little fissures or holes, there is some danger in placing it in *wet* soils, for it will often weep, and if cut, water will be seen to ooze through the joints. Also, when placed under the basement floor to keep out damp, water will invariably find its way through if there be any pressure, as from springs. To prevent vapours rising from decomposed matter in the soil, a good practice, even in dry localities, is to cover the soil before the floor boards are laid, with a layer of two inches of unslaked lime, which by slaking with damp or damp air destroys any vegetation that may have been left on the surface.

1887. We, perhaps, might have more properly spoken first of the subject of DRAINAGE and SEWERS, whereof it now becomes our duty to give some information, inasmuch as before a brick or stone of any building be laid, the architect neglects his duty if he has not provided for perfect drainage in the lowest parts of the structure. This must not be by the aid of a small stagnant tank, called a *cesspool*, often the cause of much disease in a family; but by means of a drain into some running stream at a distance from the building, or, if that be not practicable, into some far removed pond, whose exhalations shall not be blown by the prevalent winds of the spot back upon the place where they were generated, in a different form. Neither does the health alone of the family whose comfort is to be provided for, demand this consideration of drainage; for the durability of the structure is quite as much involved in good drainage as is the health of the family whose dwelling-place the house is to become: hence we are the more earnest in pressing the point. In cities, the architect cannot always accomplish this important object; but in the country he is unpardonable if he neglect it. London with its suburbs is now probably the best drained capital in Europe. The lines of sewers forming the main drainage may be deemed completed, and to have relieved the noble river of nearly all the sewage matter. Every street has its public sewer, acting more or less perfectly, and nearly every house its separate drain into the sewer, although for a time, a few years back, this rule of a separate drainage, which had long been in force, was annulled.

1888. The main drain necessary for the service of the largest house (we suppose the case of one in the country), if the fall be even but moderate, requires no large dimensions. When we see a small river draining considerable tracts of country, often in section only 8, 9, or 10 feet superficial; it may easily be conceived that the surplus water from, and rain falling on, a mansion is a quantity, even in pressing times, that exacts no large area of discharge to free the place from damp. There are few cases in which the greatest mansion would demand an area exceeding 5 feet, which a sewer 2 ft. by 2 ft. 6 in. would afford, supposing it to have a parallelogrammic section; but of course when the fall permits, a greater height would be preferable. Drains should, as well for their durability as on other accounts, be constructed with curved bottoms, but not with the lower part egg-shaped; for instance, as respects flat bottoms, take the lower parts of two drains, whose depth of running water is 1 foot, one whereof is formed with a semicircular bottom, 2 feet wide. The area of the column of water will, therefore, be 1·5708, and the length of the half curve will be 3·1416. To obtain with one foot depth of water, the same area in a drain whose bottom is flat and sides upright, we must have the width 1·5708, and the sum of the three sides touched by the water will be 3·5708. Then $3{\cdot}5708 - 3{\cdot}1416 = {\cdot}4292$ represents roughly the difference of friction or impediment in favour of the semicircular bottom in the case stated, nearly $\frac{13}{100}$ of the power being lost by the use of a flat bottom.

1888*a*. Since the introduction, about 1845, of pipes into the sewerage and drainage systems, brick drains have been discarded. But easy as it may appear to lay down pipes, unless it be done under careful supervision, the fall may hereafter be found insufficient; the fall perhaps reversed; the effective drainage stopped by carelessness in forming the joints; and so on. The chief point to be here noticed respecting this familiar subject is, that great difference exists between the vitrified stoneware pipe drains, and the glazed or unglazed earthenware pipe drains, substituted for cheapness. The sewage in the latter soon corrodes the glazing, which being removed, the half burnt earthenware sucks in the foul water and decays. Nor is it nearly so strong as the stoneware article.

1888*b*. Great diversity of opinion exists as to the effective size of a pipe required for a building. One person urges that his ten roomed house and outbuildings have never been inconvenienced by the use of a 3 inch drain, whilst other houses, with 6 inch and even 9 inch drains, have been seriously affected. Much depends, as noticed in the previous paragraph, on the fall, and on the careful laying of the pipes, and something on the quantity of water used for household purposes. Where a water closet is placed at or near the head of a drain, a stoppage of its pipe often occurs; while grease from the kitchen sink incrusting in the pipe, for want of occasional flushing with hot water, is another frequent cause. Sewers also occasionally require that assistance by flushing them from their head. One of the best arrangements proposed is that of an iron tilting cistern, to hold about 90 gallons, inserted in a brick pit at the head of a pipe sewer. This cistern with its brass bearings and plates, brickwork, stone cover, and water tap, costs about nine pounds, and if one were placed at the head of each pipe sewer in a town, and all were turned off at the same time, a material assistance in keeping the main line also clear, would be found.

1888*c*. Various arrangements are advertised for obtaining access to drains for inspection, without the necessity for breaking into them. A velocity of 2 feet per second is the least which will keep sewers clear of all ordinary obstructions; while house drains and small pipes require a velocity of 3 feet per second to keep them clear (Hurst). No new sewer can now be made in London without the previous approval of the Metropolitan Board of Works; and no drain can be laid into a sewer without the previous approval of the vestry

or district board, which has to apply to the Metropolitan Board of Works for their sanction in both cases. Many towns in England have now their Board of Health supervising the drainage of the streets and houses, pursuant to "The Public Health Act, 1848," and "The Local Government Act, 1858."

Sect. II.

BRICKLAYING AND TILING.

1889. Bricklaying, or the art of building with bricks, or of uniting them by cement or mortar into various forms, includes, in the metropolis, and mostly in the provinces, the business of walling, tiling, and paving with bricks or tiles, and sometimes plastering; but this last is rarely, if ever, undertaken by the London bricklayer; though in the country the trades of bricklaying and plastering are usually united, and not unfrequently that of masonry also. The materials used have been described in a previous part of the work, to which the reader is referred (1811. *et seq.*).

1890. The tools used by the bricklayer, who has always an attendant labourer to supply him with bricks, mortar, &c., are — 1. A *brick trowel*, for taking up and spreading the mortar, and also for cutting the bricks to any required length. 2. A *hammer*, for cutting holes and chases in brickwork. 3. The *plumb rule*, being a thin rule, 6 or 7 inches wide, with a line and plummet swinging in the middle of it, in order to ascertain that the walls are carried up perpendicularly. 4. The *level*, which is about 10 or 12 feet long, with a vertical rule attached to it, in which a line and plummet are suspended, the use whereof is to try the level of the walls at various stages of the building as it proceeds, and particularly at the window cills and wall plates. 5. The *large square*, for setting out right angles. 6. The *rod*, for measuring lengths, usually 5 or 10 feet long. 7. The *jointing rule*, about 8 or 10 feet long, as one or two bricklayers are to use it, and 4 inches broad, with which they *run* or mark the centre of each joint of the brickwork. 8. The *jointer*, which is of iron, shaped like the letter S. 9. The *compasses*, for traversing arches and vaults. 10. The *raker*, a piece of iron having two knees or angles, dividing it into three parts at right angles to each other, the two end parts being pointed and equally long, and standing upon contrary sides of the middle part. Its use is to rake out decayed mortar from the joints of old walls for the purpose of replacing it with new mortar, or, as it is called, *pointing* them. 11. The *hod*, which is a wooden trough shut close across at one extremity and open at the other. The sides consist of two boards at right angles to each other, from the meeting whereof a handle projects at right angles to their union. It is used by the labourer for conveying bricks and mortar to the bricklayer; for which purpose, when he has the latter office to perform, he strews dry sand on its inside, to prevent the mortar from sticking. 12. The *line pins*, which are of iron, for fastening and stretching the line at proper intervals of the wall, that each course may be kept straight in the face and level on the bed. The pins have a line attached to them of 60 ft. to each pin. 13. The *rammer*, used for trying the ground, as well as for beating it solid to the utmost degree of compression. 13. The *iron crow* and *pick axe*, for breaking and cutting through walls or moving heavy weights. 14. The *grinding stone*, for sharpening axes, hammers, and other tools. The following ten articles relate entirely to the preparation and cutting of guaged arches. 15. The *banker*, which is a bench from 6 to 12 ft. long, according to the number of workmen who are to work at it. It is 2 ft. 6 in. to 3 ft. wide, and about 2 ft. 8 in. high. Its use is for preparing the bricks for rubbed arches, and for other guaged work. 16. The *camber slip*, a piece of wood usually about half an inch thick, with at least one curved edge, rising about 1 inch in 6 feet, for drawing the sofite line of straight arches. When the other edge is curved, it rises about half that of the other, that is, about half an inch in 6 feet, for the purpose of drawing the upper line of the arch, so as to prevent it becoming hollow by the settling of the arch. The upper edge is not always cambered, many preferring it straight. The slip being sufficiently long, it answers the width of many openings; and when the bricklayer has drawn his arch, he delivers it to the carpenter to prepare the centre for it. 17. The *rubbing stone*. This is of a cylindrical form, about 20 inches diameter, but may be less. It is fixed at one end of the banker, upon a bed of mortar. After the bricks for the guaged work have been rough-shaped by the axe, they are rubbed smooth on the rubbing stone. The headers and stretchers, in return, which are not axed, are called *rubbed returns* and rubbed headers and stretchers. 18. The *bedding stone*, which is a straight piece of marble 18 or 20 inches in length, of any thickness, and about 8 or 10 inches wide. It is used to try the rubbed side of a brick, which must be first squared to prove whether its surface be straight, so as to fit it upon the leading *skew back*, or leading end of the arch. 19. The *square*, for trying the bedding of the bricks, and squaring the sofites across the breadth of the bricks. 20. The *bevel*, for drawing the sofite line on the face of the bricks. 21. The *mould*, for forming the

face and back of the brick, in order to reduce it in thickness to its proper taper, one edge of the mould being brought close to the bed of the brick when squared. The mould has a notch for every course of the arch. 22. The *scribe*, a spike or large nail, ground to a sharp point, to mark the bricks on the face and back by the tapering edges of the mould, for the purpose of cutting them. 23. The *tin saw* used for cutting the sofite lines about one eighth of an inch deep, first by the edge of the level on the face of the brick, then by the edge of the square on the bed of the brick, in order to enter the brick axe, and to keep the brick from spalting. The saw is also used for cutting the sofite through its breadth in the direction of the tapering lines, drawn upon the face and back edge of the brick; but the cutting is always made deeper on the face and back of the brick than in the middle of its thickness, for the above-mentioned purpose of entering the axe. The saw is also used for cutting the false joints of headers and stretchers. 24. The *brick axe*, for axing off the sofites of bricks to the saw cuttings, and the sides to the lines drawn by the scribes. The bricks being always rubbed smooth after axing, the more truly they are axed the less labour will be requisite in rubbing them. 25. The *templet*. This is used for taking the length of the stretcher and width of the header. 26. The *chopping block*, for reducing the bricks to their intended size and form by axing them. It is made of any piece of wood that comes to hand, from 6 to 8 inches square, and generally supported upon two 14-inch brick piers, if only two men work at it; but if four men, the chopping-block must be lengthened and supported by three piers, and so on according to the number employed at it. It is about 2 ft. 3 in. in height. 27. The *float-stone*, which is used for rubbing curved work to a smooth surface, such as the cylindrical backs and spherical heads of niches, to take out the axe marks. It is, before application to them, made of a form reversed to the surface whereon it is applied, so as to coincide with it as nearly as possible in finishing.

1891. Before adverting to the *bond*, as it is technically called, of brick walling, which is the form of connection of the bricks with each other, we will stop to observe, that in working walls, not more than 4 or 5 feet should be brought up at a time; for as, in setting, the mortar shrinks and a general subsidence takes place, the part first brought up, if too large in quantity, will have come to its bearing before the adjacent parts are brought up, and thus fissures in the work and unequal settlements will take place. In carrying up any particular part above another, it should always be regularly sloped back to receive the adjoining parts to the right and to the left. On no account should any part of a wall be carried higher than one scaffold, except for some very urgent object.

1892. Previous to the reign of William and Mary, all the brick buildings in this island were constructed in what is called *English bond*; and subsequent to the reign in question, when, in building as in many other cases, Dutch fashions were introduced, we regret to say, much to the injury of our houses' strength, the workmen have become so infatuated with what is called *Flemish bond*, that it is difficult to drive them out of it. To the introduction of the latter has been attributed (in many cases with justice) the splitting of walls into two thicknesses; to prevent which, expedients have been adopted, which would be altogether unnecessary if a return to the general use of English bond could be established.

1893. In chap. i. sect x. of this book (1550. *et seq.*) we have spoken generally on walls; our observations here, therefore, in respect of them, will be confined to brick walls and their bond.

1894. *English bond* is that disposition of bricks in a wall in which (except at the quoins) the *courses* are alternately composed of *headers* and *stretchers*. In brick walling, and indeed in stone walling also, a *course* means the horizontal layer of bricks or stones whereof the wall is composed, being contained between two faces parallel to the horizon, and terminated on each side by the vertical face of the wall. The mass also formed by brick or stones in an arch are also termed courses, but receive the name of concentric courses. The term header is applied to a brick or stone whose small head or end is seen in the external face of the wall; and that of stretcher, to a brick or stone whose length is parallel to the face of the wall. We are therefore to understand by English bond, a continuation either of header or stretcher, continued throughout in the same course or horizontal layer, and hence we have described it as consisting of alternate layers of headers and stretchers (*fig.* 616.), the former serving to bind the wall together in a transverse direction or widthwise, and thus prevent its splitting, whilst the latter binds it lengthwise, or in a longitudinal direction. None but the English bond prevents the former occurrence, as work executed in this way, when so undermined as to cause a fracture, separates, but rarely breaks through the solid brick, as if the wall were composed of one entire piece.

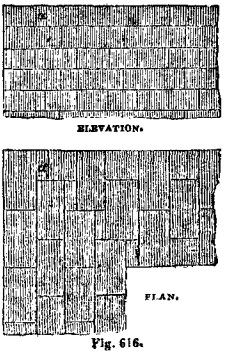

Fig. 616.

1895. The ancient Roman brickwork was executed on this

principle; and its extraordinary durability is as much to be attributed to that sort of work being used for bonding it together, as to its extraordinary thickness.

1896. In this, as well as Flemish bond, to which we shall presently come, it will be observed, that the length of a brick being but 9 inches, and its width 4½ inches, in order to *break* the joints (that is, that one joint may not come over another), it becomes necessary near the angles to interpose a quarter brick or *bat*, *a*, called a *queen closer*, in order to preserve the continuity of the bond in the heading course. The bond, however, may equally be preserved by a three-quarter bat at the angle in the stretching course, in which case this last bat is called a *king closer*. In each case an horizontal lap of two inches and a half is left for the next header. The figure above given is that of a two-brick or 18-inch wall, but the student will have no difficulty in drawing, on due consideration of it, a diagram of the bond for any other thickness of wall; recollecting, first, that each course is formed either of headers or stretchers. Secondly, that every brick in the same course and on the same face of the wall must be laid in the same direction, and that in no instance is a brick to be placed with its whole length against the side of another, but in such way that the end of one may reach to the middle of the others that lie contiguous to it, excepting in the outside of the stretching course, where three-quarter bricks, or king closers, will of course be necessary at the ends, to prevent a continued upright joint in the face of the work. Thirdly, that a wall crossing at right angles with another will have all the bricks of the same level course in the same parallel direction, whereby the angles will be completely bonded. We shall close these observations with a recommendation to the young architect, founded on our own experience, on no account, in any building where soundness of work is a desideratum, to permit any other than English bond to be executed under his superintendence.

1897. *Flemish bond* is that wherein the same course consists alternately of headers and stretchers, which, in appearance, some may fancy superior to that just described. Such is not our opinion. We think that the semblance of strength has much to do with that of beauty in architecture. But there is in the sufferance of Flemish bond a vice by which strength is altogether lost sight of, which we shall now describe. It was formerly, though now partially, the practice to face the front walls of houses with guaged or rubbed bricks, or with at least a superior species of brick, as the malm stock; in the former cases, the bricks being reduced in thickness, and laid with a flat thin joint frequently, what the workmen call a *putty joint*, for the external face, the outer and inner work of the same courses in the same wall, not corresponding in height, could not be bonded together except where occasionally the courses fell even, where a header was introduced from the outside to tie or bond the front to the internal work. Hence, as the work would not admit of this, except occasionally, from the want of correspondence between the interior and exterior courses, the headers would be introduced only where such correspondence took place, which would only occur in a height of several courses. Thus a wall two bricks in thickness, if faced on both sides, was very little indeed better than three thin walls, the two outer half a brick thick, and the middle one a brick or 9 inches thick. Bricklayers having little regard for their character will, if not prevented by the architect, not only practise this expedient, but will also, unless vigilantly watched, when a better sort of brick is used for the facing, cut the headers in half to effect a paltry saving of the better material. In walls of one brick and a half in thickness, the strength of the wall is not diminished by the use of Flemish bond so much as in those of greater thickness, as may be seen by the diagram (*fig.* 617.). Many expedients have been invented to obviate the inconveniences of Flemish bond; but we think it rather useful to omit them, lest we should be considered as parties to a toleration of its use, for the continuation whereof no substantial reason can be assigned. As we have before observed, all that can be alleged in its favour is a fancy in respect of its appearance: but were the English mode executed with the same attention and neatness bestowed on the Flemish method, we should say it was equally beautiful; and therefore we shall thus close our notice of it.

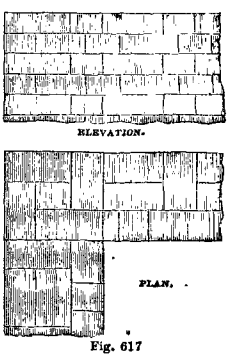

Fig. 617

1898. The two principal matters to be considered in brick walling are, first, that the wall be as strong as possible in the direction of its length. Secondly, that it be so connected in its transverse direction that it should not be capable of separating in thicknesses. To produce the first, independent of the extraneous aid of bond timbers, plates, &c., it is clear that the method which affords the greatest quantity of longitudinal bond is to be preferred, as in the transverse direction is that which gives the greatest quantity of bond in direction of the thickness. We will, to exemplify this, take a piece of walling 4 bricks long, 4 bricks high, and 2 bricks thick, of English bond: in this will occur 32 stretchers, 24 headers, and 16 half headers to break the joint, or prevent one joint falling over another. Now, in an equal piece of walling constructed in Flemish bond, there will occur only 20

stretchers and 42 headers; from which the great superiority of English bond may be at once inferred.

1899. *Bond Timber* should be used in pieces as long as circumstances will admit. In walls where the thickness will allow of it, some prefer that the timber should be laid in the centre, so that when it decays no material damage is done. Also that in case of fire, the bond timber is not affected by it. If so placed, when dressings of wood are required, wooden plugs must be provided to which to secure them. When a fire occurs and the bond is next the inside face, it is burnt out, and the strength of a thin wall, say 9 or 14 inches thick, is seriously affected thereby. Two or three tiers in the height of the room are usually employed.

1899*a*. However useful timber may be in bonding thin walls whilst the brickwork is yet green, it has for some years been entirely superseded by *hoop iron bond*. This consists of narrow and thin strips of iron (see SMITHERY) laid between two courses of bricks. The iron should be tarred and sanded, the former as a preservative from rust, the latter to afford a firmer hold to the mortar. Some authorities go so far as to state that hoop iron bond, unless it is set in a cement course, is not so efficient as wood bond. A tier of bond is placed in each three feet of height, one strip of iron to each half brick. In extensive works, or in special cases, two, three, or more, tiers are recommended. In addition to the use of concrete on clay soils, it may be occasionally useful to build all the footings for four or six courses in height of brickwork in cement, each course well bonded with hoop iron, laid both longitudinally and diagonally; it is perhaps better than a course of Yorkshire stone (par. 1882.) as the bond is continuous. During the execution of the works, the iron is continued through all openings as with wood bond; the latter is cut away when requisite, but the former should be turned down against the brickwork. The laps at a junction should be carefully made to secure the continuity of the tie. An addition to the plain band of iron has been introduced, and *Tyerman's patent notched hoop iron bond* has been extensively employed. It consists in forming a slight notch at intervals of 11¾ inches on both sides alternately, and turning it up in succession, in contrary directions, forming a triangular piece, whereby a better key is obtained upon the bricks and mortar.

1900. *Mortar joints.* The propriety of using mortar beds as thin as possible, has been inculcated in this work, and most specifications state that four courses of brickwork formed of the ordinary sized bricks are not to rise more than 11¾; sometimes 12 inches is named, as the joints should not exceed ¾ths of an inch. When good mortar is used that sets rapidly, the joint might be thicker than thus allowed. In Roman and most Eastern work, the joint was usually 1 and 1¼ inches thick, and where the mortar has been good, such buildings so executed are sound after centuries of wear. "In modern practice, in all masonry and brickwork where strength is required rather than ornament, thick beds and joints of good mortar will be useful. Thin bricks or tiles will also be better than thick bricks, as the material will be better burned, and consequently more enduring. More good mortar can also be used, which in such work gives strength." Such is the practical opinion of R. Rawlinson (*Builder*, xxi. page 152), who declares that "the proportion of mortar to rubble stonework should be about 1 to 3, that is, in 4 cubic yards of rubble wall there should not be less than 1 cubic yard of mortar. In brickwork (ordinary bricks) the proportion will be 1 to 4. If thin bricks be used, or if very small stone be used for rubble-work, the proportions may be as 1 to 1." It has been urged that the peculiarity of early Norman masonry, even of the period of bishop Gundulph, is that of very thick beds of mortar. Mr. Rawlinson further adds, "As a general rule, buildings whether of marble, limestone, sandstone, or of brickwork alone, or of brick and terracotta combined, which are ornamental in character, must all have *thin* joints and beds. Thick beds and joints of mortar would destroy the harmony of design by deteriorating the appearance of labour bestowed on the rich materials in such buildings."

1900*a*. The fine joints of rubbed brickwork are formed by lime putty, being mortar reduced to the consistency of cream; the bricks are dipped into it to take up a coating, and then driven close upon each other. Ashlar work is usually set in a putty formed of lime, white lead, and a small quantity of very fine sand.

1900*b*. A defect in the solidity of work arises from the use of many of the hollow, perforated, and machine made, bricks, in that their surfaces are so hard as to prevent the mortar sticking, unless they be first coated with sand. Many walls on being pulled down have shown that the mortar had had no hold upon the bricks, a key had been formed between two bricks by the holes at their ends, but no proper adhesion had taken place. A wall built in first-rate work, could be easily shaken to pieces even after it had been built four or five years. In all brickwork, especially in hot weather, the bricks should be soaked in water (par. 1832*a*.); and even some of the courses of bricks be sprinkled with water from a rose watering pot. This precaution tends to prevent the absorbent material brick withdrawing all moisture from the mortar before the lime has had time to crystallize. The defect, however, of so doing is, that the walls take longer to dry (par. 1832.); as is also the case when grouting (par. 1860.) is employed.

1900*c*. The mortar or cement should be such as will quickly set, to prevent the superincumbent weight pressing the joints closer, and thereby causing settlements, which even with the greatest care, often take place unequally. As often as it is conjectured, from the nature of the soil, or from the foundation being partly new and partly old, that the work will not come to its bearing equally, it is better to carry up the suspected parts separately, and to leave at their ends what are called *toothings*, by which junctions may be made when the weaker parts have come to their regular sound bearing.

1900*d*. The thickness of walls has furnished the subject of previous pages: we shall therefore only add, that too much care cannot be bestowed on strengthening all angles as much as possible, and well connecting the return of one wall into another; that piers or pilasters are exceedingly useful in strengthening walls, inasmuch as they act by increasing the base whereon the whole stands; and, lastly, that in carrying up walls to any considerable height, it is usual to diminish their thickness by *sets off* as they rise. In houses, above the ground-floor, the sets off are usually made on the inside, having the outside in one face; but, if it be possible, it is better to set off equally from both faces, because of the better balance afforded.

1900*e*. *Joints* in brickwork are finished on the face in several ways. The most common are the 'struck joint,' which is merely finishing the joint by drawing the point of the trowel along it: or 'jointed,' as done by a tool called a *jointer* (par. 1890, art. 8), so as to leave a line impressed on the mortar: or 'flush joint,' in which case the joint is drawn at top and bottom with the trowel when the brick is laid, and afterwards when the mortar is partially set, the middle of the joint is flushed flat with the 'jointer;' this is sometimes called a 'high joint.'

1901. A bricklayer, with the assistance of one labourer, can, if he be so inclined, lay in one day about 1000 bricks in common walling; but the trades unions now prevent him from laying more than about one-third that number. Occasionally, for a higher remuneration some non-union man may be found to lay near the former number, and then he would complete a rod of brickwork in four days and a half, its area being 272¼ feet superficial of the thickness of one brick and a half. When, however, there are many apertures or other interruptions to his work, he will be proportionably longer over it. The weight of a rod of brickwork is about 13 tons. Generally it may be taken as consisting of from 4300 to 4500 stock bricks, allowing for waste according to the quality of the bricks, 27 bushels of chalk lime, and 3 single loads of drift sand, or 18 bushels of stone lime and 3½ single loads of sand. In cement, of 36 bushels, and the same quantity of sharp sand. A rod of brickwork laid dry contains 5370 bricks. A cubic yard contains 384 bricks, and requires about 6½ cubic feet of sand and 2½ of lime. A ton of bricks contains about 373 on an average. 330 well burnt bricks weigh generally about 20 cwt., so that a cubic foot weighs about 125 lbs.

1902. *Brick-nogging* is a method of constructing a wall or partition with a row of posts or quarters 3 feet apart, whose intervals are filled up with occasional plates of wood with brickwork between. It is rarely more than the width of a brick in thickness, and the bricks and timbers on the faces are flush. It should never be used where thickness can be obtained for a nine-inch wall. A half brick-nogged partition will require about 500 bricks; a whole brick-nogged partition about 1000 bricks; and with brick on edge about 340.

1902*a*. A *half-brick partition* built in mortar is now adopted in many of the model lodging houses, sometimes with an occasional hoop-iron bond. These are built four, five, and six stories in height, the joists of the floors steadying them as they are carried up. Of course the apartments in such places are small in all their dimensions, being about 12 feet long, 9 feet wide, and from 9 to 9 feet 6 inches in height. A half-brick wall of greater dimensions may be built in cement, and when the floor joists are laid upon it, it becomes very steady, strong, and little likely to be injured by a fire. Thin slabs of stone have been used as partitions in small houses near a quarry. Tiles in cement with wood plugs inserted for the dressings, make a sound partition, and when plastered direct upon the tiles, it takes up much less room than a one-brick wall.

1902*b*. Many varieties of *hollow bricks* are made for a similar purpose. The "patent bonded hollow bricks or rebated tiles" (*fig. 617a.*) of Hertslet and Co., were employed in 1846–7, by Henry Roberts in the model lodging house in George Street, St. Giles's; as also in the so-called Prince Albert's model houses, erected in Hyde Park in 1851, and removed to Kennington Park. A is a bond stone; B concrete, C floor boards, and D a tie rod. When used for partitions, or for roof and floor arches, these hollow bricks are fireproof, deaden sound more effectually, and are considerably lighter, than solid brickwork. Such bricks as a lining to stone or flint walls, supersede the necessity for battening. They are also well adapted for cottage floors. *Hollow bricks* can be made by any good tile machine,

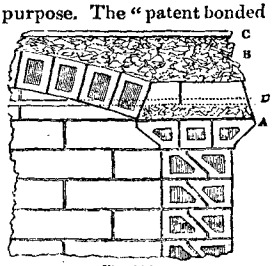

Fig. 617a.

in the same manner as ordinary drain-pipes. They are more compressed, require less drying, and are generally better burned than ordinary bricks. An interesting and complete paper on the subject, with illustrations on the English and French systems of making hollow bricks, is given in the *Building News* for 1858.

1902c. HOLLOW WALLS, formed of ordinary stock bricks, were employed for two-story cottages early in this century. Three methods are usually adopted in the construction of a wall. I. All the bricks placed on edge, as *fig.* 617*b*, the stretchers and headers breaking joints, and the headers forming the bond. Many persons consider that this arrangement produces a disagreeable appearance on the outside face. II. All the bricks laid flatways, but the stretchers are sawn in half, so as to leave a space of 4½ ins. between them; and in laying the headers, as *fig.* 617*c*. care must be taken only to fill up with mortar the joints over the half brick on edge, so as to leave the middle of the joint open. III. To lay all the bricks flat in the usual English bond, leaving a space of about 2 inches between each face, and to make up the thickness thus caused, viz. 11 or 11½ inches, by a bat to each header. This may be varied by using a less number of headers, and placing two or three stretchers together, according to the strength of the work required. At Southampton, and perhaps elsewhere, headers are not used, the two faces being bonded together by hoop-iron cramps (*fig.* 617*d*.), with forked ends, $\frac{13}{16}$ths by $\frac{1}{10}$th inch, tailing into the frogs of the brick (*fig.* 617*e*.), and having a bend in the middle of its length partly as a strut to the inside, and partly to prevent any moisture running along it to the inside face. A cast iron cramp (*fig.* 617*f*.) is also made, ½ inch by $\frac{3}{16}$ths in. thick. Jennings has adopted *bonding bricks* of stoneware for hollow walls. *Fig.* 617*g*. shows the application of the three sizes; A is 13½ inches long, to be used in garden walls and other places where an uniform face is not required; B is 11¼ inches long,

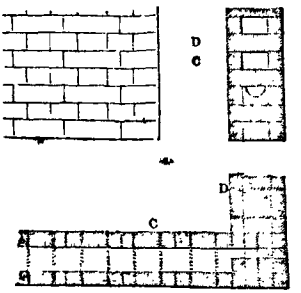

Fig. 617*c*.

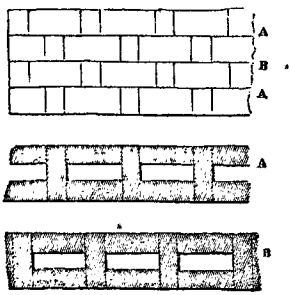

Fig. 617*b*.

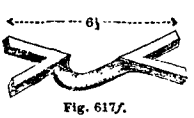

Fig. 617*f*.

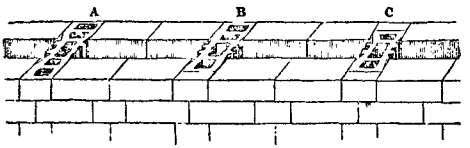

Fig. 617*g*.

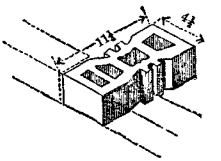

Fig. 617*h*.

where but one uniform face is required (the brick is shown to a larger size in *fig.* 617*h*.) the end of the bond brick being faced with a closure of the same material as the wall; and C is a brick 9 inches long, when both faces are to be uniform, closures being used at both ends of it. A 16 inch hollow wall can be built with a 9 inch inside wall, a 2 inch space, and a 4½ inch wall outside, and so on. Such a wall is of very common erection in North America, and it is found to stand very well for country villas of good dimensions.

1902*d*. Much diversity of opinion exists as to whether the space so left should be ventilated by air gratings just above the ground, and also by others under the coping, to obtain a current of air and secure dryness if water be blown through the outer brickwork. In exposed situations, especially on the sea-coast, if hollow walls are not built, either the wall has to be slated on the outside; or it has to be battened on the inside, even when cemented on the outside, to prevent damp showing on the interior surface. Hollow cement blocks have lately been introduced in France, and are said to be cheap, as durable as stone, ventilation easily secured, and provide for the ready formation of shafts for warm air or for flues. The blocks have a resistance of 430 lbs. to the square inch, and are adapted to walls about 20 inches thick as well as to partitions of less width.

1902*e*. Mr. Taylor has adopted an arrangement of an interior face of common bricks B, with an exterior *facing block* of a better manufactured brick A, in the shape of the letter

L, leaving a cavity of 2 or more inches between them, (*fig.* 617*i*).

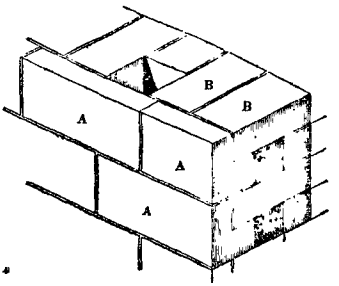

Fig. 617*i*.

1903. Groined arches. A groin is the angular curve formed by the intersection of two semi-cylinders or arches. The centering for raising the more simple groins that occur in using brick arches, belongs to the section Carpentry. The turning a simple arch on a centre only requires care to keep the courses as close as possible, and to use very little mortar on the inner part of the joints. In executing a brick groin, the difficulty arises from the peculiar mode of making proper bond, at the intersection of the two circles as they gradually rise to the crown, where they form an exact point. At the intersection of these angles, the inner rib should be perfectly straight and perpendicular to a diagonal line drawn on the plan. After the centres are set, the application of the brick to the angle will immediately show in what direction it is to be cut. With respect to the sides, they are turned as for common cylindric vaults. Mr. George Tappen, an architect of great practical skill, introduced a method of constructing groins rising from octangular piers, which had the advantage of not only imparting strength to the angle, which in the common groin is extremely deficient, but of increasing the space for the stowage or removal of goods, and further, of strengthening the angles of the groin in this construction by carrying the band round the diagonals (*fig.* 618.) of equal breadth, and thus affording better bond to the bricks.

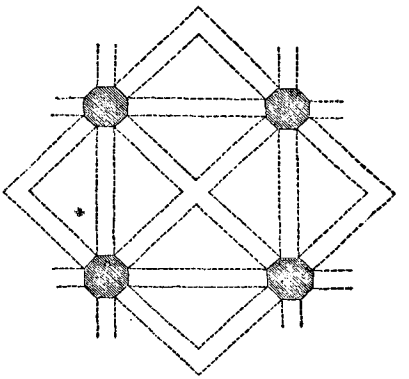

Fig. 618.

1903*a*. The Metropolitan Building Act, 1855, requires that *under* a public way, an *arch*, if it be employed, of a span of not more than 10 feet, is to be at least 8½ inches thick; when not exceeding 15 feet, it must be 13 inches at least; and beyond that width the thickness requires special approbation. If of iron construction or other incombustible material, it must be built in a manner approved by the district surveyor. An arch *over* a public way must be formed in the above manner, but a span not exceeding 9 feet must be 8½ inches thick at least. A like special approval is required if the arch or floor be of iron.

1903*b*. *Light arched flat floors*, composed of bricks cemented with gypsum or plaster, have been in common use in Roussillon from time immemorial. Rondelet is of opinion that the segment of a circle is a better form for such arches than the low semi-ellipse. He describes apartments of 18 feet by 25 feet, as used at the War Office at Versailles, covered with brick arches of which the rise was only $\frac{1}{13}$th part of the span and in five stories. The coach-houses and stables of the Marshal de Belle Isle at Bisy near Vernon, were arched in an elliptical form, having a rise of $\frac{1}{7}$th of their span, which was 32 feet 9¾ inches. They were not finished until a year after the walls and roof had been completed. The walls were built of rubble-work having chains of cut stone at intervals of about 16 feet. They were 2 feet 8¼ inches thick, being about equal to $\frac{1}{12}$th part of the span. These arches were formed of a double thickness of bricks laid flat, and in plaster, built in succession, with the vertical joints broken. The haunches were filled up with rubble stone in plaster. The springing was formed by notches in the wall, above which the regular courses of stone projected inwards as gathering courses. Above all, a third course of flat bricks was laid horizontally, forming a pavement. Rondelet considers that arches of small and light materials cemented by gypsum become as it were one body, and exert little or no lateral pressure upon the abutments excepting at first, because that cement has a tendency to swell in setting. Rondelet relates that a stone of 4000 lbs. or 5000 lbs. weight was dropped upon one of these arches from a height of 4 or 5 feet, which made a large hole through the arch, without doing any further injury. If mortar be used the parts must be thicker, and the centering left, until the work has set. Portland and Roman cement might be better than gypsum for work in England. Rondelet also states that it is better to use coved arches springing from the four walls, than a common arch springing from two opposite walls only.

1903*c*. The *arched brick floors*, used in the dwellings for workmen at Birkenhead, by the architect C. E. Lang, were 7 feet in span, worked in half brick except at the springing

and the skew-backs, with a few three quarter and other parts of bricks inserted, so as to form a toothing or vertical bond with the concrete with which the spandrels were filled. The six or seven courses at the crown were wedged in with slate while the mortar was wet, and in no instance did the least subsidence take place at the crown, although subjected to very severe trials, such as that of men jumping from the walls upon the arches. The span of 7 feet is perhaps the limit of a half brick arch turned in mortar with the ordinary rough brick. The arches rise about one inch to every foot in span. Tiles were laid in mortar on the concrete, which made the thickness of the floor at the crown of the arch 5½ inches. There were altogether about 1200 arches of this kind turned, and without the slightest accident. This explains the usual method of forming fireproof floors, by turning brick arches between iron girders, which are in large spans tied together at the springing by iron tie rods; a subject which has been so often considered and discussed, and nowhere more so than at the Institute of Architects, as detailed in their *Transactions*.

1903*d*. The *Dennett arch*. A fireproof system, invented by Messrs. Dennett, of Nottingham, and used for the last twelve years. They execute a groin, dome, or circular ceiling of any length, width, or height, without tie rods or intermediate supports, at much less cost than can be done by any other fireproof material: circular ceilings of 36 feet diameter, with coffers in them, or any amount of decoration can be executed on the soffits, and the upper surface can be finished smooth in itself, or with stone, wood, tiles, cement, or asphalte, and a current of air ensured underneath. Very few iron girders are required. For floors, although in an arched shape, it is in reality a beam, as a complete floor can be turned from wall to wall, resting on a projection of brickwork, and the material be left without any abutment. Its durability equals stone; and its strength is equal to brickwork. The floors are bad conductors of heat; leave no harbour for vermin; ventilating pipes may be laid in them, and also flues. The material can be used for a sound proof construction, when laid in the old method between wood joists.

1903*e*. Three courses of plain tiles laid in cement and well bonded have been for many years employed for slightly curved roofs to form terraces; roofs for cellars under paving; as roofs over small back buildings, and for similar purposes. Where the walls are well backed up, tie rods may not be necessary. It has been asserted that the tiles should *not* be covered with the cement. Portland or other cements laid on brick arches, or on tile, or on a flat concrete roof supported by iron joists; also asphalted roofs; all generally crack and let in wet, especially where there is any traffic on them, or their foundations are not perfectly stable. At Austin and Seeley's artificial stone works, New Road, flat roofs, floors and steps are formed in their material. The terrace roofing is formed of plain tiles in three courses, rendered on the top to the thickness in all of about 4 inches, carried over by arches slightly cambered, springing from small brick piers, and tied by light iron rods, which form their chord line. These flats have an immense weight upon them, and are cast in one piece, as it were, there being no perceptible joint; they are completely water-tight, and can be easily cleaned.

1903*f*. Light arches may likewise be formed by placing thin *iron plates* between joisting of iron or wood, bending them to a slight curve, and filling in above them with concrete to form solid work. *Mallet's buckled wrought iron plates*, are usually made in square or oblong shapes, having a slight convexity in the middle, and a flat rim round the edge, called the *fillet*. These plates are considered the best form yet devised for the iron covering of a platform, and are usable for the above purposes. They are often placed so that the convex part is compressed, and the flat fillet stretched; when they give way under an excessive load, it is usually by the crushing or crippling of the convex part. The safe loads given in the tables published by the inventor, for a plate 3 feet square, ¼ inch thick, and with 1·75 inch of curvature, are 4·5 tons for a steady load, and 3 tons for a moving load. The square form, supported and fastened at all the four edges, is the most favourable to strength. The buckled plates used by Mr. Page for the platform of new Westminster bridge measure 84 inches by 36 inches, with a curvature of 3½ inches, and thickness of ¼ inch; they bear 17 tons on the centre without giving way (Rankine, *Civil Engineering*).

1903*g*. In India, where all buildings of any importance have *flat roofs*, the long established practice is to form them of tiles, mostly 12 inches square and 1½ inches thick; in Calcutta they are generally 18 inches square and 2 inches thick. These tiles are made with great care: they are burnt the same as pottery, and are used both for roofing and for flooring. In roofing a room of 20 feet span, it is first covered with teak beams 12 inches deep by 8½ inches broad, placed 3 feet apart, which carry *burgahs* or joists, 3 inches square, fixed 1 foot apart, and on these the tiles are placed in two layers carefully jointed with each other. Above them is laid 6 inches of concrete, formed of broken bricks and lime, spread evenly and beaten down to 4 inches, and beaten until the mass is dry; finally it is plastered, and rubbed or polished. If well made and of good materials, it is impervious to wet, and will last as long as the timber under it.

1903*h*. A floor, or even a flat roof, patented by Bunnett in 1858, is formed of hollow bricks having the two sides each composed of two parallel inclines, and each about half the depth of the block, connected by a horizontal or nearly horizontal plane, and the two

inclines on one side are parallel with those on the opposite side. Through these bricks, tie rods are passed and secured at each end to wall plates formed of angle iron; the whole is then screwed up, when the bricks form a slight curved arch in section, and from the inclined sides they over and underlap one another and mutually give and receive support from the neighbouring blocks. This invention has been carried to 21 feet span with a rise of about $2\frac{3}{4}$ inches, and about 13 feet wide. Other arches have been constructed for the purpose of testing its bearing powers. One of the latter, 15 feet between the bearing walls, and 2 feet 3 inches wide, was loaded with 4 tons 10 lbs. (or 267 lbs. to the square foot), and was quite elastic. The deflection was about $\frac{9}{16}$ths of an inch. The bricks are put together with Portland cement and sand. Each brick is $10\frac{3}{8}$ inches long, by $9\frac{3}{8}$ inches wide, and 6 inches thick; and weighs 21 lbs. 100 square feet comprise:—

	ton.	cwt.	qrs.	lbs.
145 bricks, weighing	1	7	0	21
Cement and sand	0	2	3	19
Angle iron and tension bars (bars being 4 feet apart)	0	2	2	5
Total weight per square	1	12	2	17

1903*i*. Pots and jars and hollow bricks have all been used in arched work to reduce its weight. Sir John Soane employed jars in the dome of the Rotunda at the Bank of England, which is about 65 feet in diameter. In floors of arched work either iron ties must be used to prevent the walls being forced out, or iron girders employed, thus subdividing the length, and the work arched across the length, i. e. between each girder. The *Builder* of 1849 records the use of hollow bricks in the vaulting of St. George's Hall, at Liverpool; and Daly's *Revue Générale* for the same year, the use of such bricks in walls.

1903*k*. The Indians about Nagpore, build their *stone vaults* in a peculiar method, which might be followed with advantage in some cases in this country. At the springing, stones of a considerable depth are used, having the intrados cut to the form of the curve, six courses are laid, the upper one having a groove five inches wide and two deep. Then stones of a smaller depth are laid, each having a groove cut in one face, 2 inches in depth and 4 inches in breadth, with a corresponding projection in their other face, the groove being on the upper side to receive the projection formed in the next course. About eight courses having been laid, it then becomes necessary to prevent the work from falling inwards. At every 10 feet in length two strong rods are placed horizontally across the chasm, and the ends are forced into the grooves. From these courses as from a new base, similar grooved stones to those already described are continued, the length of each course contracting until the key course is inserted. When this last course is completed, the rods are sawn across at either end of the finished vault, and the work continued. When the arch or vault is of considerable span, a series of bases may be adopted, each at higher points than the other, until one part is keyed. A slight scaffolding supports the workman, but no frame or centering is used.

1903*l*. Concrete and cement blocks. Blocks formed of Roman cement, puzzuolana, lime, and sand, were soon suggested for such a purpose. Those made without the cement were found to be longer in setting, but eventually became the strongest. To these combinations, potsherds were added, as Pliny relates was in use in the time of the Romans, increased toughness resulted. The late Mr. Walker, engineer, possessed specimens of Dutch terras, which had been used in Woolwich dockyard in the reign of George III. These were of very great hardness; in fact, gunpowder had to be used in breaking up the dock where it had been employed. For concrete and mortar for the river wall of the Houses of Parliament he used 2 measures of sand, 1 of puzzuolana, and 1 of lime. Mr. Lee used Portland cement, Portland stone chippings, sand, and shingle, in blocks in cubes of 16 feet and upwards, made in moulds, for the breakwater at Dover. Mr. Blashfield had made experiments for that work, with Lancashire terras mixed with broken tiles and sand; but it was not deemed equal in hardness to the Portland cement concrete blocks.

1903*m*. The use of *concrete* has extended from the foundations of buildings, backings of wharfs and retaining walls, to the employment of it for the backing of vaults to produce a level surface; for the substance of fireproof floors; for the base of floors, pavements, and roads; for backing to the abutments of arches; and in the shape of pisè work for the walls, floors, &c. of houses, bridges, and moles, by French, if not, as in some cases, by English, engineers.

1903*n*. *Atkinson's* or *Mulgrave cement* was used by its patentee for concrete blocks of shingle, sand, and cement, used as ashlar stone, in the case of a house at the corner of Mount Street, Grosvenor Square, still standing in a substantial condition. Concrete in small blocks, known as *Ranger's patent artificial stone*, has been used to a limited extent in the construction of domestic buildings. It was employed in the additions to the College of Surgeons, Lincoln's Inn Fields, 1835–6; a guard-house in St. James's Park; the Imperial Assurance Office, in Pall Mall; and in a row of houses in the Western Road, at Brighton, partly in blocks and partly in moulds as pisè work. This process is not continued, probably from the mortar not being properly mixed in the first instance, and the

concrete being exposed too soon to the action of the weather, for it dries unevenly and cracks in all directions.

1903*o*. *Buckwell's Granitic Breccia stone* was patented about 1858 to compete with brickwork in price; its strength and durability being greater, and its bulk and weight considerably less. It was impermeable to wet and never vegetated, so that for pavements, and linings for tanks, it appears to have answered well; but for some reason not ascertained, the manufacture of it was lately given up. It could have been manufactured in a single piece, of a weight varying from 1 cwt. to 60 tons or more; also in slabs from 5 feet to 100 feet superficial; and to any contour. *Wheeble's Reading Abbey patent concrete stone*, formed with Bridgewater stone lime, when made into a brick, was found to be equal in strength to a common stock. Some specimens never attained the strength of concrete except in a case where large gravel or flint was the chief ingredient. *Messrs. Bodmer's patent compressed stone bricks*, compounded chiefly of 1 part of hydraulic lime and 7 of siliceous sand, well mixed, are subjected to great pressure in moulds. Upon removal, the bricks are piled up in the open air, when induration commences, and the material is converted into stone. They appear to be ready for use after six weeks' to two months' exposure, and experiments show a steady progressive increase in strength as they advance in age. When eleven days old they crushed at 3·77 tons; at twenty-two weeks from 5·4 to 6·95 tons; and at sixty-three weeks a pressure of upwards of 8 tons was reached without effect.

1903*p*. *Coignet's Béton Aggloméré* has been employed in France in the construction of a church in the park of Vésinet near St. Germain, from the designs of M. Boileau, and into the construction of which he has also introduced cast and wrought iron. The *béton* is formed with all the mouldings of Gothic architecture both externally and internally. It was built similarly to pisè work, though it is also applicable for blocks, like stone, in which manner he has lately executed some bridges of 140 feet span. The very hard frosts of January 1865 had not appeared to have had any effect on the *béton* at the church, which was being executed at the time, and is described in the *Builder* for November 1864; views are also given in the volume for 1865. It is stated that such structures cost only about one-half or perhaps one-third of the expense of a stone building, with greater decoration.

1904. Many ornamental brick cornices may be formed by but little cutting, and changing the position of the bricks employed, and several, indeed, without cutting, by chamfering only. Of late years the machines for making bricks have permitted the extensive use of moulded bricks of different forms, which have entirely superseded the more artistic advantages of cut brickwork to required outlines or ornamental details.

1905. *Niches* may be formed in brickwork. They constitute the most difficult part of the bricklayer's practice. The centre will be described under the section CARPENTRY. The difficulty in forming them arises from the thinness to which the bricks must be reduced at the inner circle, as they cannot extend beyond the thickness of one brick at the crown or top, it being the usual as well as much the neatest method to make all the courses standing.

1906. TILING is the operation of laying the tiles on a roof for the covering of the building, and is effected with either plain or pan tiles; the former is the most secure description. Plain tiles are laid at different gauges, (see par. 2301). 210 plain tiles laid flat will cover a square of tiling which can be laid in a day by a man and his assistant. As old tiles are of a much better consistency than those now made, it may be desirable to re-use the best of them with new tiles to fill in; in which case the old ones are laid with the best effect in courses, say three or four rows of new tiles and two of old tiles; or laid in a diapered pattern, according to the quantity. Pan tiles are generally pointed in mortar, which if it be not very strong will not stick; in consequence of this, tile roofs require fresh pointing every few years, especially in exposed situations. A practice has obtained of late years, when plain tiles are set in mortar, not to peg more than about one tile in ten; this should not be permitted, as with the decay of the mortar the tiles slip down. An ancient custom prevailed, to bed the tiles in hay or moss, and when the roof is of the *full pitch* this suffices without mortar; they may even then be laid dry. But with any less pitch, some precaution must be used to keep out drifting snow, and such wet as may be blown up between the tiles lifted by the force of the wind. In lieu of oak pegs, extra large flat headed wrought nails, made of pure zinc or of zinc and copper, have been used, and it has the advantage of allowing a tile to be replaced from the *inside* of the roof, by lifting up the others to place in the tile and drop in the nails in a few seconds. The utility of the mortar is questioned in the *Builder* for 1865.

1907. Pan tiling is laid to a 10 inch gauge; and 180 pan tiles will cover a square. From the frequent repairs necessary to tiled roofs, slating has become the most useful covering, and is generally employed, except for the most common buildings. See par. 2301.

1908. The tiler's tools are—the *lathing hammer*, with two gauge marks on it, one at 7 ins., the other at 7½ inches. The *lathing staff*, of iron, in the form of a cross, to stay the cross laths and clinch the nails. The *tiling trowel*, to take up the mortar and lay it on the tiles: it differs from the brick trowel, in being longer and narrower. The *bosse*, made of wood, with an iron hook, to hang on the laths or on a ladder, for holding the mortar and tiles. The *striker*, a piece of lath about 10 inches long, for separating and taking away the

superfluous mortar at the feet of the tiles. The *broom*, to sweep the tiling after it is struck.

1908*a*. The bricklayer has often to provide temporary COVERINGS to buildings whilst his or other operations are being performed. The commonest method is that of merely nailing old boards laid weather-board fashion to any slope that may be desirable. The next is the use of tarpaulins supported by open boarding, and secured to posts or scaffolding rigged up for the purpose; this must be efficiently done, as in case of high winds the whole may be carried away. Felt is also used for temporary roofs, for which purpose, likewise, Messrs. Rigg and Co. have a new material composed of canvas covered with a water-proofing substance having vegetable oil as a basis, and consequently not liable to the desiccating action of the rays of the sun.

1908*b*. PAVING. When neither slate, granite, Yorkshire or other stone, flint, nor shells, are used for paving, recourse is had to bricks, tiles, and asphalte. A yard superficial of *brick paving* requires 82 to 36 stocks laid flat; 48 to 52 laid on edge; 36 paving bricks laid flat, 82 on edge; 140 Dutch clinkers on edge; 9 twelve inch tiles; and 13 ten inch tiles. Brick paving is laid *flat* in sand; jointed in mortar; jointed in cement; and laid *on edge*, in the same manner. Tile paving is generally laid in sand or mortar, (par. 2282). Besides the ordinary brick, some others have been introduced, especially for stables and yards, such as the *Terro metallic grooved bricks*; and the *Adamantine clinker*, which is said to be superior to the *Dutch clinker* in shape, colour, density, and wear (par. 1830). The second is made near Little Bytham Station, on the Great Northern Railway. The clay contains the unusually high proportion of 69 per cent. of silica.

1908*c*. Ordinary *tile paving* is made of about 8, 9, 10, 11, or 12, inch tiles of a hard and well burnt clay. The 11 inch tiles used in the footpaths, which are each 14 feet 6 inches wide, of new Westminster bridge, were made by Blashfield, and are laid diagonally, (par. 1839). The Staffordshire paving tiles, in blue, red, and buff, are very durable, and for general purposes as effective as the more expensive qualities for inlaid purposes. It will be sufficient here to notice the use of encaustic or inlaid tiles for *paving*, and of mosaic tiles for the same purpose; and of tesseræ for mosaic work, whether for pavements or for wall decorations.

1908*d*. ASPHALTE has now taken the place of most other sorts of manufactured pavements of the same character. A solid foundation is prepared by a bed of concrete of hydraulic lime and gravel, with a layer of finer concrete over it, to fill up the vacuities. When dry, the asphalte is put on, of a thickness for private purposes of about ⅜ths. of an inch; for public purposes, one inch is not too much: it should be applied as hot as possible. A small quantity of pure quick lime is added to the asphalte when in ebullition, to prevent it melting by the heat of the sun. This material has been much used for thrashing floors of barns, for malt-houses, armouries, tun rooms, (sometimes from 2 to 2½ inches thick), dissecting rooms, dog kennels, exercising yards, mills of many kinds, granaries, verandahs, and numerous factories and buildings. For carriage traffic, the asphalte is embedded with small Guernsey granite chippings. This material is *not* suitable for any floor where oil, tallow, or other greasy matter is employed. All the public paving laid in asphalte in London has been removed as unsatisfactory, the causes of which we are not fully informed: the public generally complain of the heaviness which is felt when walking over it, whereas stone gives a springing motion to the feet. The Polonceau and Seyssel Asphalte Company indent the surface into small squares affording a foothold for horses in a stable; this is also considered useful for flat roofs and paving generally. Wright's *marble tar pavement* for yards, play-grounds, &c. has been used for the platforms of the Windsor, and the Waterloo stations, and in the middle part of the quadrangle of Somerset House

SECT. III.

MASONRY.

1909. Masonry is the science of preparing and combining stones so as to tooth, indent, or lie on each other, and become masses of walling and arching for the purposes of building. The tools of the mason vary as the quality of the stone upon which they are to act. About the metropolis the value of stone is considerable; and it is accordingly cut into slips and scantlings by a saw moved horizontally backwards and forwards by a labourer. In those parts where stone is abundant, it is divided into smaller scantlings by means of wedges. The principal tools of the mason are the *mallet* and *chisels*, the latter being formed of iron, except at the steel end, and the cutting edge being the vertical angle. The end of the chisel struck by the mallet is a small portion of a spherical surface, and projects on all sides beyond the adjoining part or hand hold, which increases in magnitude towards the middle of the tool, to the entering or cutting edge. The other tools of the mason are a

level, a plumb-rule, a square, a bevel, with straight and circular rules of divers sorts, for trying surfaces in the progressive states of the work.

1910. In London, the tools used to work the face of a stone are, successively, the *point*, the *inch tool*, the *boaster* (the operation of working with which is called *boasting*, as that with the point is called *pointing*), and the *broad tool*. The use of the point leaves the stone in narrow furrows, with rough ridges between them, which are cut away by the inch tool, and the whole made smooth by the boaster. The point is from $\frac{1}{8}$ to $\frac{3}{8}$ of an inch broad, the boaster is 2 inches wide, and the broad tool $3\frac{1}{2}$ inches at the cutting edge, which in use is always kept perpendicular to the same side of the stone. It performs two sorts of operations. Thus, imagine the impression made by the whole breadth of the tool at the cutting edge, to be called a cavity; in one operation, the successive cavities follow one another in the same straight line, until the breadth or length of the stone is exhausted; successive equidistant parallel lines are then repeated in the same manner, until the tool has passed over the whole surface. This operation produces a sort of fluted surface, and is called *stroking*. In the other operation, each successive cavity is repeated in new equidistant lines throughout the length or breadth of the stone; then a new series of cavities is repeated throughout the length and breadth of the stone; and thus until its whole length or breadth is gone through. This operation is called *tooling*. The tools for working the cylindrical and conical parts of mouldings are of all sizes, from $\frac{1}{8}$ of an inch upwards. Those for working convex mouldings are not less than half an inch broad, except the space be too confined to admit of such breadth.

1911. A stone is taken out of winding principally with points, and finished with the inch tool. In London, the squared stone used for facing buildings is usually stroked, tooled, or rubbed.

1912. In those parts of the country where the stone saved by the operation of sawing is not enough to compensate for the labour, the operation is altogether performed with the mallet and chisel.

1913. When stones, previous to the operation of hewing, are very unshapely, a *stone axe*, *jedding axe*, *scabbling-hammer*, or *cavil*, is used to bring the stone nearly to a shape; one end of the jedding axe is flat, and is used for knocking off the most protuberant angular parts, when less than right angles; the other end is pointed for reducing the different surfaces to nearly the intended form.

1914. In Scotland, besides the above described sorts of work, there are some other kinds, termed *droved*, *broached*, and *striped*. Droving is the same as that called random tooling in England, or boasting in London. The chisel for broaching is called a *punch*, and is the same as that called a point in England. Broached work is first droved and then broached, as the work cannot at once be regularly done with the punch. Striped work must also be first droved and then striped. If broaching is performed without droving, which is sometimes done, it is never so regular, and the surface is full of inequalities. Of the three kinds of surfaces obtained, the droved is the cheapest.

1915. It is, however, to be observed, that the workmen will not take the same pains to drove the face of a stone which is to be afterwards broached, as in that of which the droving is to remain the final finish. When the surface of stone is required to be perfectly smooth, it is accomplished by rubbing with sand or gritstone, and it is called rubbed work.

1915*a*. Some useful practical remarks for obtaining the face to stone in mediæval work, is given in Denison's *Lectures on Church Building*, 1856, p. 216. "The mode of working mouldings depends a good deal upon the kind of stone used. In that from Steetly near Worksop, employed almost exclusively outside the new church at Doncaster, and in the Ancaster stone, used for pieces of window tracery and mullions too large for the blocks that can be got from Steetly, and in the Brodsworth stone, the mouldings are all completed with a *drag*. I do not use the word 'finished,' because that means going over the work to put a particular kind of surface upon it after it is really completed. On the other hand, the Crookhill stone, of which all the pillars and a few other parts are made, would utterly defy any such small tooth-comb work, as a drag; nothing under a chisel with a heavy hammer will touch it. Again, some stone from Huddlestone is too tough and cheese-like for dragging, and the mouldings in it are completed by shaving them with a chisel, something like wood carving. The effect of that is very good, because a chisel run along in that way will always make a rather undulating surface, though smooth enough to the touch, even to please the finger of a clerk of the works. In some real Norman arches, which had been covered with plaster for centuries, the mouldings showed that the drag or tool had never been allowed to make the marks directly across; generally they are oblique and sometimes parallel to the direction of the moulding. Worked in this way, the stones will be sure to show themselves distinctly, and the effect of the mortar staining the stones for a little distance from the joints, produces anything but a bad effect. Tuck-pointing, to rather rough masonry especially, *i.e.*, making prominent joints in mortar, with the edges cut quite straight and square, is another chance of spoiling work. After a few years this generally splits off," and the building may look at last as it should have done at first. The mortar should be finished within the face of the stone.

1915*b*. Grey granite, or moorstone as it is called in Cornwall, is got out in blocks by splitting it with a number of wedges applied to notches *pooled* in the surface of the stone, about four inches apart. The *pool holes* are sunk with the point of a *pick*, much in the same way as other hard quarry stones are split. The harder the moorstone the nearer it can be split to the scantling required. Generally speaking, granite has no planes of stratification, and it works or cleaves equally well in every direction; but in the porphyritic varieties there is a rough kind of arrangement of the crystals; and in gneiss there is a species of layer, formed by plates of the mica, which is plainly discernible. When brought to near the size required, it is first *scabbled* by a hammer with a cutting face 4½ inches long by 1½ inches wide, weighing 22 lbs.; then brought to a *picked face* with a pick or pointed hammer weighing 20 lbs., formed by two acute angled triangles, joined base to base by a parallelogram between them thus ; and if to be *finely wrought or fine picked*, it is further dressed with a similar pointed hammer, reducing the roughness to a minimun. The finer finish or *fine axed face* is produced by a hammer or axe with a sharp edge on both sides, weighing 9 lbs.; for *fine work* the "patent axe" is also used, which is a hammer formed of several parallel blades screwed together, capable of being taken to pieces when required to be sharpened. Polishing can then be done by machinery, the granite being rubbed by iron rubbers with fine sand and water, and finished with other materials.

1915*c*. Aberdeen red granite possesses the property common to all granites, that of a distinct plane of cleavage, which, though not perceptible to the eye, is at once recognisable under the hammer of the workman, and of course can be wrought with much greater precision and effect with the bed, than transversely to it. This bed bears no traceable relation to the natural joints of the rocks, which are indefinite in their directions; and still less so to their stratification. The grey granites are but slightly affected with cleavage, being capable of being *blocked* with the hammer with about equal facility in every direction. The local varieties of worked granite differ somewhat from those used in England, and are, I. *Hammer-blocked*, as in foundations, plinths, &c. II. *Scappled blocks*, squared with the heavy pick, as in docks and heavy engineering works. III. *Picked*, a better finish than No. II. IV. *Close picked*, the bed and arrises made fair, and the outer surfaces made as fine as the pick will make them; used in ashlar work, &c. V. *Single axed*, a finer finish than No. IV., and used in quoins, rebates, cornices, &c., in house building. And VI. *Fine axed*, the finest finish before polishing, given to dressed granite by means of the *patent axe*, used in the best work in house building, cemetery memorials, and as a finish to contrast with polished work.

WALLING.

1916. In stone walling the bedding joints are usually horizontal, and this should always, indeed, be so when the top of the wall is terminated horizontally. In building bridges, and in the masonry of fence walls upon inclined surfaces, the bedding joints may follow the general direction of the work.

1916*a*. Footings of stone walls should be built with stones as large as may be, squared and of equal thicknesses in the same course, and care should be had to place the broadest bed downwards. The vertical joints of an upper course are never to be allowed to fall over those below, that is, they must be made, as it is called, to *break joints*. If the walls of the superstructure be thin, the stones composing the foundations may be disposed so that their length may reach across each course from one side of the wall to the other. When the walls are thick, and there is difficulty in procuring stones long enough to reach across the foundations, every second stone in the course may be a whole stone in breadth, and each interval may consist of two stones of equal breadth, that is, placing header and stretcher alternately. If those stones cannot conveniently be had, from one side of the wall lay a header and stretcher alternately, and from the other side another series of stones in the same manner, so that the length of each header may be two thirds, and the breadth of each stretcher one third of the breadth of the wall, and so that the back of each header may come in contact with the back of an opposite stretcher, and the side of that header may come in contact with the side of the header adjoining the said stretcher. In foundations of some breadth, for which stones cannot be procured of a length equal to two thirds the breadth of the foundation, the works should be built so that the upright joints of any course may fall on the middle of the length of the stones in the course below, and so that the back of each stone in any course may fall on the solid of a stone or stones in the lower course.

1917. The foundation should consist of several courses, each decreasing in breadth as they rise by sets off on each side of 3 or 4 inches in ordinary cases. The number of courses is necessarily regulated by the weight of the wall and by the size of the stones whereof these foundations or footings are composed.

1918. Walls are most commonly built with an ashlar facing, and backed with brick or rubble-work. In London, where stone is dear, the backing is generally of brick-work, which does not occur in the north and other parts, where stone is cheap and common. Walls faced with ashlar, and backed with brick or uncoursed rubble, are liable to become

convex on the outside from the greater number of joints, and, consequently, from the greater quantity of mortar placed in each joint, as the shrinking of the mortar will be in proportion to the quantity; and therefore such a wall is inferior to one wherein the facing and backing are of the same kind, and built with equal care, even supposing both sides to be of uncoursed rubble, than which there is no worse description of walling. Where a wall consists of an ashlar facing outside, and the inside is coursed rubble, the courses at the back should be as high as possible, and the beds should contain very little mortar. In Scotland, where there is abundance of stone, and where the ashlar faces are exceedingly well executed, they generally back with uncoursed rubble; in the north of England, where they are not quite so particular with their ashlar facings, they are much more particular in coursing the backings. Coursed rubble and brick backings admit of an easy introduction of bond timber. In good masonry, however, wooden bonds should not be continued in length; and they often weaken the masonry when used in great quantity, making the wall liable to bend where they are inserted. Indeed, it is better to introduce only such small pieces, and with the fibres of the wood perpendicular to the face of the wall, as are required for the fastenings of battens and dressings.

1919. In ashlar facing, the stones usually rise from 28 to 30 inches in length, 12 inches in height, and 8 or 9 inches in thickness. Although the upper and lower beds of an ashlar, as well as the vertical joints, should be at right angles to the face of the stone, and the face and vertical joints at right angles to the beds in an ashlar facing; yet, when the stones run nearly of the same thickness, it is of some advantage, in respect of bond, that the back of the stone be inclined to the face, and that all the backs thus inclined should run in the same direction; because a small degree of lap is thus obtained in the setting of the next course, whereas, if the backs are parallel to the front, no lap can take place when the stones run of an equal depth in the thickness of the wall. It is, moreover, advantageous to select the stones so that a thicker one and a thinner one may follow each other alternately. The disposition of the stones in the next superior course should follow the same order as in the inferior course, and every vertical joint should fall as nearly as possible in the middle of the stone below.

1920. In every course of ashlar facing in which the backing is brick or rubble, *bond*, or, as they are called in the country, *through* stones should be introduced, their number being proportioned to the length of the course; every one of which stones, if a superior course, should fall in the middle between every two like stones in the course below. And this disposition should be strictly attended to in all long courses. Some masons, in carrying up their work, to show that they have introduced a sufficient number of bond stones into their work, choose their bond stones of greater length than the thickness of the wall, and knock or cut off their ends afterwards. But this is a bad practice, as the wall is liable to be shaken by the force used in reducing, by chiselling or otherwise cutting away the projecting part, and sometimes with the chance even of splitting the bond stone itself.

1921. In piers, where the jambs are coursed with ashlar in front, every alternate jamb stone should go through the wall, with its bed perfectly level. If the jamb stones are of one entire height, as is often the case when architraves are wrought upon them, and also upon the lintel crowning them, of the stones at the ends of the courses of the pier which are to adjoin the architrave jamb, every alternate stone should be a bond stone; and if the piers be very narrow between the apertures, no other bond stones will be necessary in such short courses. When the piers are wide, the number of bond stones is to be proportioned to the space. Bond stones, too, must be particularly attended to in long courses above and below windows. They should have their sides parallel, and of course perpendicular to each other, and their horizontal dimension in the face of the work should never be less than the vertical one. The vertical joints, after receding about three quarters of an inch from the face of the work with a close joint, should widen gradually to the back, so as to form hollow wedge-like figures for the reception of mortar and *packing*. The adjoining stones should have their beds and vertical joints filled with oil-putty, from the face to about three-quarters of an inch inwards, and the remaining part of the beds with well-prepared mortar. Putty cement is very durable, and will remain prominent when many stones are in a state of dilapidation, through the action of the atmosphere upon them. The use of the oil-putty is at first disagreeable, from the oil spreading over the surface of the contiguous stones; but after a time this unpleasant look disappears, and the work seems as though of one piece.

1922. All the stones of an ashlar facing ought to be laid on their natural beds. From inattention to this circumstance, the stones often flush at the joints; and, indeed, such a position of the lamina much sooner admits the destructive action of the air to take place. Methods of building in cement and concrete blocks, are noticed in the previous section.

1922*a*. RUBBLE-WORK. A wall consisting of unhewn stone is called a *rubble* wall, whether or not mortar is used. This species of work is of two kinds, coursed and uncoursed. In the former, the stones are gauged and dressed by the hammer, and thrown into different heaps, each

containing stones of the same thickness. The masonry is then laid in horizontal courses, but not always confined to the same thickness. The uncoursed rubble wall is formed by laying the stones in the wall as they come to hand, without gauging or sorting, being prepared only by knocking off the sharp angles with the thick end of the scabbling hammer.

1922*b*. Apparently, wherever there was any difficulty in obtaining stone, the mediæval builders employed the worst of all methods of construction in walling, viz., concrete or rubble-work between the two faces of squared stone. In the early period of mediæval art, flint or rough rubble, with "short and long work" to the quoins, seems to have been very general; this "short and long work" was also used in faced walls; in both cases the short work consists of stone upon its bed, and alternates with the long work or stone upright: the short work ought to serve as bond throughout the walls. In the 12th century the use of rubble in conjunction with worked stone became frequent. The chief defect, frequently considered one of the merits, of this system, consists in the omission of sufficient bond both in piers and walls; the occurrence of joints in angles is too frequent; in fact, any expedient seemed better than the trouble of making a back-joint.

1922*c*. Kentish Ragstone. This material, now so extensively employed for mediæval work in the metropolis and suburbs, is never used *internally*, as it *sweats*, that is, the condensed moisture from the atmosphere is not absorbed, and will show itself even through two coats of plastering. *Hassock stone*, however, which is the sandstone separating the beds of the ragstone, the sand being sufficiently agglutinated to allow of its being raised in blocks, must never be used *externally*. It is easily worked, and makes a good lining for ragstone walls, as it does not sweat. It should be roughly squared, for if not done, the crumbling nature of the stone would endanger the security of the work, should it be exposed to any unequal pressure: it must not be placed where it would be exposed to very great pressure, as in arches, jambs, &c. Hassock may be procured in London at from 6*s*. to 7*s*. per cord (3 feet cube), in roughly squared pieces; while rough rag is about 5*s*. per ton, and rag headers about 12*s*. 6*d*. per ton.

1922*d*. Sunk and moulded work in so hard a material is to be avoided, and so much wrought surface would cause decay. In using ragstone ashlar, it must be laid upon its natural bed, otherwise rapid decay will almost certainly follow, arising from the thinness of the strata, for blocks of a large size can seldom be entirely freed from hassock; and even what appears to the eye as blue stone, retains for a considerable distance inward the perishing nature of its enveloping crust. A block of ragstone, if the face be worked, will present in damp weather an appearance precisely similar to the heart and sap of timber. In the case of copings, &c., where one bed is exposed, the stone should be *skiffled* (or *knobbled*) as much as possible from the upper side, so as to expose only the soundest portion of the stone to the action of the atmosphere. In some situations, as mullions, door and window jambs, an unsightly appearance would be produced by too exact an attention to the beds of the stone, as the ashlar is generally too small to range with more than one course of headers. In these cases the old masons seem to have departed from their usual rule, and to have set the blocks on end, so as to embrace two or three courses; but as the depth of the block required to work an ordinary jamb or mullion is not very great, it is not difficult to get the whole thickness required out of the heart of the stone.

1922*e*. Stone of the smaller layings are generally worked into headers; it is common to work one side of the stone to a rough face with parallel sides, without paying much attention to the beds and joints, which often recede at an acute angle with the face, so as to bring the stones, when laid, to a closer joint. Such stones, however, must be properly pinned in behind, and carefully bonded with the work at back. Headers are generally knocked out to six, seven, eight, or nine inch gauge for the height; the length and tail being determined by the size of the stone: on the face they do not vary much from the square form. Formerly headers were set on their natural bed, therefore it is not unusual to find stones in an old wall entirely gone from this cause.

1922*f*. In the Whitelands bridge bed, a very free working stone of a bluish colour can be got 12 feet long with certainty, and the Horsebridge bed yields a good stone to a length of 15 feet. The white rag, the lowest of the beds in the quarry, tumbles to pieces on exposure to the air (Whichcord, *Kentish Ragstone*, 1846).

1922*g*. In its mechanical properties, ragstone possesses some of the qualities of granite, though in an inferior degree. In respect to resistance to pressure, it stands next to granite in the list of British stones; but when loaded for a transverse strain, the numerous vents to which even the best layings are liable, renders it untrustworthy for lintels, or in a suspended position, without much precaution. In the former case of lintels and architraves, three stones, arch jointed, gives the requisite security.

1922*h*. Whinstone, a material, in one form or another, found almost over all Scotland, makes a very durable arch for bridge work, when well built with good mortar, the stone being in its nature weather proof. In the neighbourhood of Edinburgh, whinstone arches have been erected since about 1770, the greatest span being about 60 feet. The Messrs.

Smith, of Darnick, stated, in the *Transactions* of the Institute of British Architects, that they had erected bridges with semi-elliptical arches of the spans of 51 feet, and of 62½ feet, of whinstone faced with hewn stone. A bridge, almost entirely of whinstone, having an arch 68½ feet span, the depth of the masonry being 2½ feet on the average, was erected in 1833; while another, 76 feet 4 inches span, at Falshope, was entirely of whinstone, with a rise of about 18 feet. It sunk about seven inches when the centre was struck, but no broken stone was observed. The depth of the arch, requiring three breadths of stone to make it up, was 3 feet; their average thickness was 3½ inches; but it varied from 1½ to 6 inches. The stones were laid as close as possible, and in crossing the bond the work was made firm, but the stones were not dressed straight upon the beds. Its cost was 360*l.* exclusive of the digging for the foundations.

1922*i*. The most annoying part in the building of rubble arches, is the slowness of the setting or drying of the mortar, as until the mortar is able to bear considerable resistance the arch is extremely supple, and easily bent out of its proper curve when the centre is struck. This bridge stood five weeks before that measure was considered advisable. Cement would perhaps be best for large rubble arches, and even if expensive, the whole cost would be cheaper than a bridge of hewn stone. With cement, almost any kind of stone, even the refuse of a slate quarry, might be worked into an arch of almost any extent.

1922*k*. FLINTWORK.—In the chalk districts, the houses of the fifteenth century are frequently faced with flints, cut and trimmed, and arranged with great skill and effect. One of the best examples is a house in St. Andrew's, at Norwich, next the cemetery, a fragment of the decorated period of Gothic architecture, in which the flint work is so delicately finished that a penknife can scarcely be inserted in the interstices.

1922*l*. As flint itself is practically imperishable, and as flintwork becomes, when perfectly set, a mass of concrete, it produces substantial work, if great care be taken in its manipulation. But flint walls frequently fail, by bulging while they are in course of construction, and splitting when they are old. On any sufficient natural cause, as the giving way of the foundation, they are riven into immense masses; hence a flint building gets out of repair less readily than a stone one, but if it suffer at all, it is very apt to become a complete ruin.

1922*m*. Flint walls intended for durability should not be less than two feet in thickness, built slowly and solidly, flushed up with stiff strong mortar compounded of quick-setting stone lime and coarse sharp sand free from loam. As flint is a non-absorbent, bricks and tiles are often worked into the middle of the walls to assist in the induration of the mortar; but for the sake of economy, lumps of hard chalk, pebbles, and flat-bedded stones are frequently used as the principal components of the *core* or middle of the wall. The work must be kept as dry as possible during its erection, as well as subsequently; frost is found soon to level the work while saturated with water.

1922*n*. Flint walls are strengthened by *lacing courses*, formed of bricks three or four courses deep, not generally showing outside. At Cambridge, Brandon, and elsewhere, they do show, and are used every two or three feet. The object is not only to get a continuous bond, but to bring the work to a level bed, and again start fair. When round flints are split, and the thicker portion is kept, as usual, at the face of the wall, driving rains are readily conducted by the inclination of the upper bed of each course to the middle of the wall, and by keeping it damp conduce to its decay; but as flints are seldom split at right angles to their axis, they can be so laid in the work as to be flush on the face as well as level, and the lower bed must be firmly pinned up with fragments. It is desirable that cavities for drainage, with exit holes at the plinth level, be formed in the middle of the wall by building in rods of wood or iron vertically, and drawing them up as the work progresses. The face is sometimes finished by inserting in the mortar joints *gallets*, or the sharp fractured bits of flint, when the work is called *galleted* or *garreted* (*Dictionary of Architecture*).

1922*o*. Amongst examples of a systematic parsimony of labour and material in mediæval art, may be noticed the characteristic *tables* or courses, where each projection is taken out of a separate course of stone or out of the smallest stone adjoining to it. The base (*fig.* 618*a*.) and the capital (*fig.* 618*b*.) of a shaft are kept so small as to be got out of single blocks; the astragal belongs to the capital, and not, as in Roman work, to the shaft; the bell is in one stone, the abacus in another (*fig.* 618*d*.); each *order* of an arch is an independent range of stones; the hoodmould is self-existent; the sills are not dished, and the buttresses are toothed rather than bonded. In two cases, however, the use of large stones prevailed, viz., in shafts of the 13th century (in France, 1160–1230), which are long rods of stone 6, 4, or 3 inches in diameter and incapable of bearing any great weight, unless banded or bonded to the nearest wall or

Fig. 618*a*. Fig. 618*b*.

pillar, and in the springing stones of vaulting, which are worked with level beds. (See par. 2002*f*.) The horizontal courses at the bottom of the arch are also seen in the construction of large horse-shoe arches. With the 13th century, also came the decided distinction between decoration and mere construction, which employed stone vertically, not only for shafts of columns, but for mullions and tracery of windows and dwarf walls, such tracery being cut out of slabs and confined by grooves or similar means.

1923. Where walls or insulated pillars of very small dimensions are to be carried up, every stone should be carefully bedded level, and be without concavity in the middle. If the beds should be concave, as soon as the superimposed weight comes to be borne by the pier or pillar, the joints will in all probability begin to flush; and it is, moreover, better, if it be possible, to make every course in the masonry of such a pier or pillar in one stone.

COLUMNS.

1924. When large columns are obtained in a single block, their effect, from that circumstance alone, is very striking; but as this is not very often to be accomplished, the next point is to have as few and as small joints as possible; and the different stones, moreover, ought to be selected with the view, as much as possible, of concealing the joints, by having the blocks as much of the same colour as possible. It will immediately, of course, occur to the reader that vertical joints in columns are inadmissible, though in many of the great edifices at Paris such do occur, much to their detriment.

1925. The stones for an intended column being procured, and the order in which they are to be placed upon one another having been determined, we must correctly ascertain the exact diameter for the two ends of each of them. To effect this, draw an elevation of the column proposed to its full size, divide it by lines parallel to the base into as many heights as the column is intended to contain stones, taking care that none of the heights exceed the lengths the stones will produce; the working of the stones to the diameters thus obtained then becomes easy. The ends of each stone must first be wrought so as to form exactly true and parallel planes. The two beds of a stone being thus formed, find their centres, and describe a circle on each of them; divide these circles into the same number of equal parts, which may, for example, amount to six or eight; draw lines across each end of the stone, so that they will pass through the centre and through the opposite divisions of the same end. The extremities of these lines are to regulate the progress of the chisel along the surface of the stone; and, therefore, when those of one end have been drawn, those of the other must be made in the same plane or opposite to them respectively. The cylindrical part of the stones must be wrought with the assistance of a straight-edge; but for the swell of a column, a diminishing rule, that is, one made concave to the line of the column, must be employed. This diminishing rule will also serve to plumb the stones in setting them. If it be made the whole length of the column, the heights into which the elevation of the column is divided should be marked upon it, so that it may be applied to give each stone its proper curvature. But as the use of a very long diminishing rule is inconvenient when the stones are in many and short lengths, rules or rods may be employed corresponding in length to the different height.

1925*a*. The method of setting the blocks or *frustra* by the ancients, was to *dish out* the beds to obtain a truly fine joint. In the Parthenon, an outer space of 7 inches in width all round the drum, was left a perfectly level and smooth bed for actual contact. The next space, of 1 foot in width, was very slightly tooled or scratched over. The next, 9 inches in width, was made still lower by being tooled over very roughly. The remaining portion round the centre was left smooth, but was made as low as the surface of the second space. A square hole, worked at the quarry, in the centre of the shaft, was filled with a cube of hard wood, in which was a hole to receive the half of a circular pin, also of wood, suggesting the idea that when the marble *frustra* were set, they were rubbed against each other. The first drum, at the temple of Hercules at Agrigentum, when placed on the stylobate, was turned round until it had been well ground down. (*Civil Engineer*, &c. vii. p. 241.) The practice of late years, for large columns, has been to place a plate of thin lead between the beds of stone, so as to secure an equal bearing and prevent the edges flushing, any space being filled in with putty or cement. At Paris, in many of the porticoes, the columns have very deep thin rustics (*fig.* 618*c*.), which would effectually prevent any broken edges from being observed. The effect is peculiar, especially in strong sunlight. The height of the face of the stone is ·385 of a metre; the height of the channel, including the rounded arrises, is ·40, and the depth of the channel is ·85.

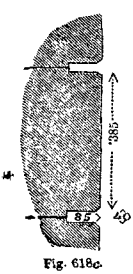

Fig. 618*c*.

1925*b*. Besides the usual mode of drawing a volute, described in par. 2576, we insert a method recommended by Mr. Gwilt for adoption. A general method of inscribing a spiral in a rectangular quadrilateral, A B C D:—Multiply the given height by the given

breadth, and divide the product by the sum of the height and breadth. Then subtract the quotient from the height. The remainder is the radius of the first quarter revolution of the spiral: The formula is $h - \frac{h \times b}{h+b} = r$ (= BE, ba or Fa). Subtract the radius aF so found from the height BD and the remainder FD will be the radius of the second quarter of the revolution, and is to be set from F to b. The difference $a\,b$ between a F and b F will form one side of the quadrilateral *abcd*. Subtract the radius Fb from the width CD and the remainder GC will give bd the other side of the quadrilateral *abcd* (which points will be the centres for the portions of the first revolution), and will be a figure similar to, or of the same proportions as, the given quadrilateral ABCD. Then dG will be the radius of the third quarter of the revolution and Hc the radius of the fourth quarter. In the quadrilateral or parallelogram *abcd*, draw the diagonals *ad*, *bc*, and draw bH, cutting the diagonal *ad* in *e*, then will *e* be a point for the formation on the diagonals of another parallelogram *efgh*, whose angles (as in that first made) will be the centres for the radii of the second revolution. By again drawing Hf to cut the diagonal *ad*, another parallelogram may be formed, and so on to bring out the spiral. X is the centre part to a larger scale (*Builder*, xviii. p. 364).

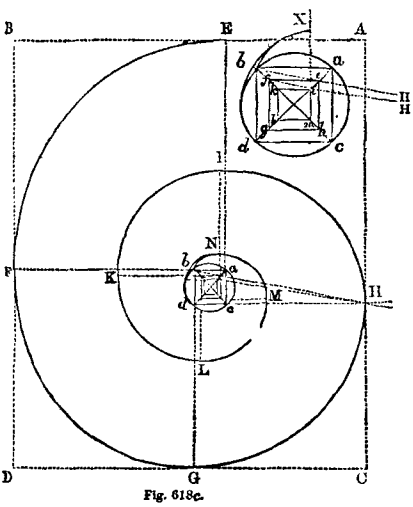

Fig. 618*c*.

1925*c*. From the nature of the formula it is evident that when $h : b$ is but by a trifle in a greater ratio than 1·61 : 1 the first radius will be greater than the breadth of the quadrilateral, and the spiral cannot be described within the figure. Also that when h and b are equal, the spiral vanishes, for the formula becomes $h - \frac{h^2}{2h}$ and the first radius is equal to half the side of the circumscribing square. Hence a circle is inscribed. Also that as the height and breadth approach equality the number of revolutions increases. In the diagram the height is taken at 27 equal parts and the breadth at 23 of such parts. Upon trial it will be found that the exact proportion of the height to the breadth to bring out a spiral within the given quadrilateral lies between 1·61 : 1 and 1·62 : 1.

1925*d*. When a *pier* was to stand upon the head of a pillar, the early mediæval builders avoided an error which their ancestors often committed. Instead of turning the arches and filling up the space at the springing until there was a clean base for the pier (*fig.* 618*d*.), they built some courses of the arch-stones in single blocks exceeding the width of the pillar. When these had risen so high that the base of the pier would not interfere with the arch-stones, these horizontal courses were discontinued (*fig.* 618*e*.). A modern folly (*fig.* 618*f*.) was unknown to them. A similar system dictates the construction of a corbelled foundation for any work standing free from the general thickness of the wall. In early pointed work the intrados of an arch (as A in *figs.* 618*g*. and 618*h*.) was plumb with the face of the square block B, forming part of the capital; and equally the front of a shaft over a capital is plumb with the same square block.

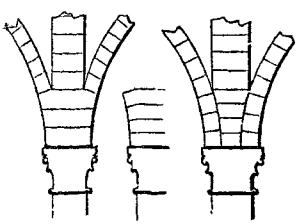

Fig. 618*d*. Fig. 618*f*. Fig. 618*e*.

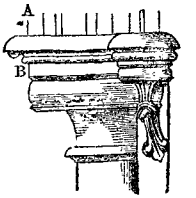

Fig. 618*g*. WESTMINSTER ABBEY.

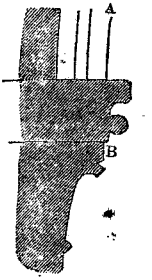

Fig. 618*h*.

1925*e*. JOGGLING. Lintels or flat arches, stone architraves, chimney mantels, and such like, when formed of small stones, are secured by joggling the joints of adjacent stones so as to form a continuous beam, the strength depending upon the solidity of the abutments. The gauged arches formed of cut bricks and used as heads to openings, are similar in

effect, but as they have neither joggles nor dowels, they are now sometimes assisted, especially in uncertain foundations, by placing under them a thin flat bar of wrought iron. Bartholomew, in his *Specifications*, 1840, gives some ancient specimens from Roman sepulchres, the three lower courses being prevented from sliding by a wedge-shaped joggle formed on the top bed of one stone, and a corresponding hole cut in the lower bed of the next stone, to receive it. *Fig.* 618*i.* is perhaps the earliest instance of a similar contrivance, and shows the oversailing portions (French *crossettes*). It is taken from

Fig. 618*i*.

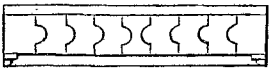

Fig. 618*k*.

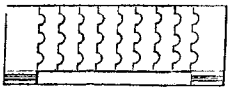

Fig. 618*l*.

Diocletian's palace at Spalato, a building often referred to as exhibiting the germs of several of the peculiar ornaments afterwards prevalent in the Romanesque and Norman styles of art (par. 198). The same principle is seen in a semicircular arch of eleven voussoirs in the lower story of the reputed tomb of Theodoric at Ravenna; in a chimney-piece at Conisborough Castle, Yorkshire; and at the gate of the Alhambra. Murphy's *Batalha*, gives, in plate 2, two instances of the same kind of construction. With double set-offs, an example is found in the upper part of Theodoric's tomb. *Fig.* 618*k.*, showing the introduction of tenons of a circular form, is the transom of the Norman west door-way of Rochester Cathedral. *Fig.* 618*l.* having three tenons to each stone, is from the mantel of a fireplace in Edlingham Castle, Northumberland.

1925*f.* Serlio, in his *Opere d'Architettura*, in Book iv. chap. v., shows two excellent modes for relieving the weight from a lintel over an opening, *figs.* 618*m.* and 618*n.* *Fig.* 618*o.* is the mode adopted by Mylne, in erecting Blackfriars Bridge, where each joggle consists of a cube foot of a hard stone. During the repairs of this structure in 1833, the decayed or broken stones were cut out, and new blocks inserted by the ingenious arrangement shown in *fig.* 618*p.* A represents the new block let in, in two parts. B is first fixed, having a hole cut to receive a plug C, which is placed in a hole in the half D; on this block being inserted in place, the plug C drops half its length into the hole in B and secures the portion D. Channels were also cut through the blocks, through which wires were placed attached to the plug to insure its sliding into its place. These were cemented up subsequently. In small works, copper plugs, or dowels would be more proper than the large blocks shown in *fig.* 618*o.*, as they require the removal of less of the substance of the arch stones as necessary for admitting joggles. Cubes, and dowels, of slate are now very much employed.

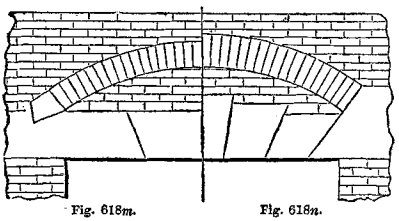

Fig. 618*m*.

Fig. 618*n*.

1925*g.* Another method much practised consists in joining, by an elbow to each voussoir, a portion of the neighbouring horizontal course of the work. This arrangement will be understood at once by reference to *figs.* 956 and 957; but, however good it may appear at first sight, it is liable to split at the junction of the horizontal portion with the radial parts, if any irregular settlement takes place. The rustic channels of arcades wrought in this form have, however, a good effect.

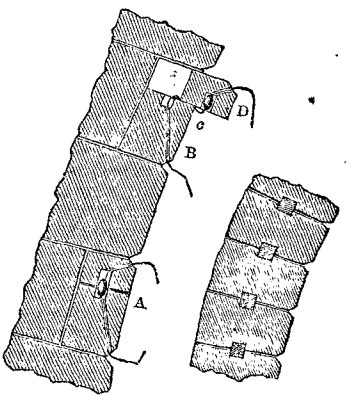

Fig. 618*p*. BLACKFRIAR'S BRIDGE. Fig. 618*q*.

1925*h.* From Viollet le Duc, *Dictionnaire*, we obtain the use of the *crossettes* as exemplified in a chimneypiece (*fig.* 618*q.*). *Fig.* 618*r.* is the lintel to the door on the north side of the Church of St. Etienne at Beauvais; and *fig.* 618*s.* that of the Church of Villers Saint Paul. *Fig.* 618*t.* shows the system described by Rondelet, in plate 27 of his valuable publication, for obtaining the requisite proportion of strength in such flat arches, as they are called. Whoever may be interested in the method of supporting and tying together by rods and bars, the stones of architraves, as formerly practised by the eminent architects of France, must be referred to the publications of Rondelet, Patte, D'Aviler, Blondel, and others of that period; in fact, the system is still introduced in the modern publications on construction, in the French school of architecture.

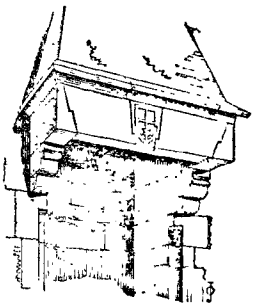

Fig. 618q.

1925*i*. To tie in ashlering to the brick wall, cramps are used, either of cast iron, wrought iron, copper, or bronze. The two latter are of course the best; the two former exfoliating by air and damp, and splitting the stone, unless perfectly secured. During the restorations at Cologne Cathedral, the cornice (above the 55 feet high windows) is 3 feet 7 inches high, and in order to connect the stones, iron hooks were put hot into the holes, which were then filled up and surrounded with asphalte. By this proceeding the iron is for ever preserved from oxidation; it has proved itself the best system, because the applications of mortar, gypsum, sulphur and lead, have all failed. On the exterior, bronze surrounded with lead has been used, which has hitherto proved satisfactory. Cramps are also now set in Portland cement.

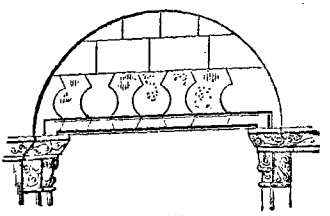

Fig. 616r.

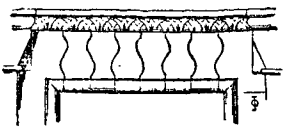

Fig. 618s.

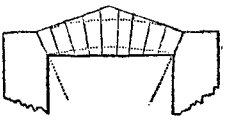

Fig. 618t.

STAIRS.

1926. Nothing to perplex will occur in carrying up stairs which are supported by a wall at both ends, because the inner ends of the steps may either terminate in a solid *newel*, or be tailed into a wall surrounding an open newel. Where elegance is not required, and where the newel does not exceed 2 feet 6 inches, the ends of the steps may be conveniently supported by a solid pillar; but when the newel is thicker, a thin wall surrounding the newel would be cheaper. In stairs to basement stories, where geometrical stairs are used above, the steps next to the newel are generally supported upon a dwarf wall.

1927. In *geometrical stairs*, the outer end of each step is fixed in the wall, and one of the edges of every step supported by the edge of the step below, and formed with *joggled* joints, so that no step can descend in the inclined direction of the plane nor in a vertical direction; the sally of every joint forms an exterior obtuse angle on the lower part of the upper step, called a back rebate, and that on the upper part of the lower step of course an interior one, and the joint formed of these sallies is called a *joggle*, which may be level from the face of the risers to about one inch within the joint. Thus the plane of the tread of each step is continued one inch within the surface of each riser; the lower part of the joint is a narrow surface, perpendicular to the inclined direction or soffit of the stair at the end next to the newel.

1928. With most sorts of stone the thickness of every step at the thinnest place need not exceed 2 inches for steps of 4 feet in length; that is, measuring from the interior angle of every step perpendicular to the rake. The thickness of steps at the interior angle should be proportioned to their length; but allowing that the thickness of the steps at each of the interior angles is sufficient at 2 inches, then will the thickness of them at the interior angles be half the number of inches that the length of the steps is in feet; for instance, a *step 5 feet long would be* $2\frac{1}{2}$ inches at that place.

1929. The stone platforms of geometrical stairs, that is, the *landings*, *half paces*, and *quarter paces*, are constructed of one or more stones, as they can be procured of sufficient size. When the platform consists of two or more stones, the first of them is laid on the last step that is set, and one end tailed in and wedged into the wall; the next stone is joggled or rebated into the one just set, and the end also fixed into the wall, as that and the preceding steps also are; and every stone in succession, till the platform is completed. When another flight of steps is required, the last or uppermost platform becomes the spring stone for the first step of it, whose joint is to be joggled, as well as that of each succeeding step, similarly to those of the first flight. The principle upon which stone geometrical stairs are constructed is, that every body must be supported by three points placed out of a straight line; and therefore, that if two edges of a body in different directions be secured to another body, the two bodies will be immoveable in respect to each other. This last case occurs in the geometrical staircase, one end of each stair stone being tailed into the

wall so as to be incapable of tilting, and another edge resting either on the ground itself, or on the edge of the preceding stair stone or platform, as the case may be. The stones which form a platform are generally of the same thickness as those forming the steps.

ON THE SCIENTIFIC OPERATIONS OF STONE CUTTING.

1930. The operations by which the forms of stones are determined, so as to combine them properly in the various parts of an edifice, are founded on strictly geometrical principles, and require the greatest care and exactness in execution. It is only by a thorough knowledge of the nature of these operations that the master mason is able to cut and carve the parts which, when joined together, compose the graceful arch, the light tracery of the Gothic vault, or the graceful and magnificent dome. The method of simple walling, and its general principles, have been given in this book, chap. i. sect. x. In what follows we propose to confine ourselves, 1st, to the leading operations necessary to *set out* the simple arch or vault, and the groins formed by it; 2d, to the forms produced by vaults with plain and curved surfaces intersecting; 3d, and lastly, to dome vaulting; giving such examples as will so initiate the student that he may, we trust, have little, if any, difficulty in resolving any case that may occur, and reminding him that if he well understand the section already submitted to him on Descriptive Geometry, his labour will be much abridged, not only in what immediately follows, but in that section which treats hereafter on Carpentry.

1931. I. Of the Construction of Arches and simple Vaults, and the Groins formed by their Intersection. In arches and simple vaults we have to ascertain the exact form of the arch in all its parts, and the direction of its joints; both which points are dependent on the geometrical properties of the curve used for the arch.

1932. *To find the joints of a flat arch without using the centre of the circle of which the arch is a part.* Divide the arch AB (*fig.* 619.) into as many equal parts as there are intended to be arch stones, at the points 1, 2, 3, &c. From A, with any convenient radius, describe an arc at *a*, and from 2, with the same radius, describe another arc, crossing the first at *a*, and join *a*1; then 1 is the first joint from A. To find the joint passing through 2; with the same radius as before, from the joints 1 and 3 as centres, describe arcs cutting each other at *b*, and draw 2*b*; then 2*b* is the second joint. In the same manner all the other joints between A and B will be found. To find the *skew backs*, or abutting joints AC and DB; with a radius equal to 1*a*, from the centre A describe an arc at C; from the centre 1, with the radius A*a*, describe an arc cutting the former at C, and draw the line AC, which will be the springing bed of the arch. In the same manner the joint BD may be found.

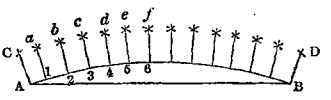

Fig. 619.

1933. The joints of any arch may be drawn with considerable accuracy by setting off at equal distances a point in the curve on each side of the place for the joint, and from these points, as centres, with any radius, arcs to intersect, through whose intersections lines being drawn, will give the directions of the joints.

1934. *To draw an elliptical arch to any two dimensions by circular arcs.* Draw the straight line AB (*fig.* 620.). Bisect AB in C by the perpendicular D*g*, make CA and CB each

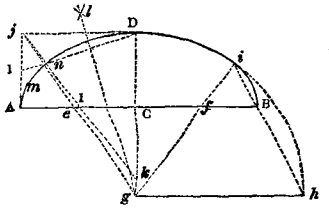

Fig. 620.

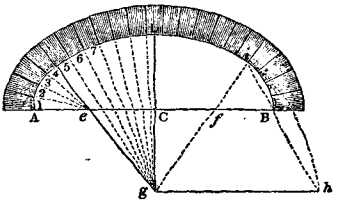

Fig. 621.

equal to half the span of the arch, and make CD equal to the height, and A*j* parallel and equal to CD. In C*g* make C*k* equal to CD. Divide A*j* and AC each into two equal parts. Through 1 in AC draw *hn*, and through 1 in A*j* draw 1D, cutting *hn* at *n*. Bisect *n*D by the perpendicular *lg*, and from *g* with the radius *gn* or *g*D describe the arc *n*D*ih*. Draw *gh* parallel to AB, and join *h*B, and produce *h*B to meet the arc *n*D*h* in *i*. Join *gi* cutting AB in *f* and make C*e* equal to C*f*. Join *ge*, and produce it to meet the arc *n*D*h* in *n*. From *f* with the radius *fi* describe the arc *i*B, and from *e* with the radius *e*A describe the arc A*mn*. Then A*m*D*i*B is the arch required.

1935. *An elliptical arch* ADB (*fig.* 621.) *being given, to draw the joints for a given number*

of arch stones. Find the centres *e*, *f*, *g* in the same manner as if the arch were to be drawn; join *ge* and produce it to meet the arch; also join *g*, *f* and produce it to meet the arc in *i*. Divide the elliptical curve ADB into as many equal parts as the number of arch stones. From the centre *e* draw lines through the points of division in the curve between A and where *ge* meets the curve and from the centre *g* draw lines through all the intermediate points between *ge* and *gf*, and lastly draw lines from *f* through all the intermediate points between *i* and B, and the parts of the lines thus drawn on the outside of the curve will be the joints of the arch stones.

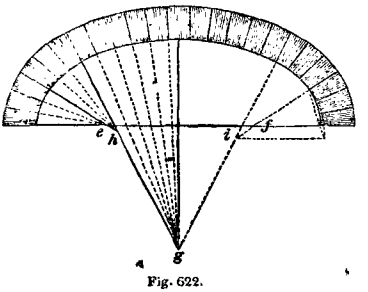

Fig. 622.

1936. In very large arches it will be desirable to find five centres, as in *fig.* 622., and these will be obtained by finding two intermediate points in each half of the curve instead of one; then bisecting each pair of adjacent points by a perpendicular, we shall have the centres *e*, *h*, *g*, *i*, *f*, to be used for drawing the joints in the same manner as in the preceding figure.

1937. The above methods are sufficient for ordinary purposes; but where strict accuracy is required, the following method is mathematically true. Suppose any joint, as *gk*, is required to be drawn (*fig.* 623.), and that the point D is the middle of the arch and the point C the middle of the springing line; then with the distance CA or CB, from the point D describe an arc at *e* and another at *f* to cut AB at *e* and *f*. Draw *eg* and *fg*; produce *eg* to *i* and *fg* to *h*, bisect *hgi* by the straight line *gk*, which will be the joint required. In the same manner, by drawing lines from *e* and *f* to each point of division, and bisecting the angle, lines for the other joints may be drawn.

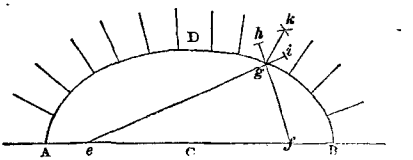

Fig. 623.

1938. *To draw a Gothic arch to any given dimensions* (*fig.* 624.). Draw the straight line

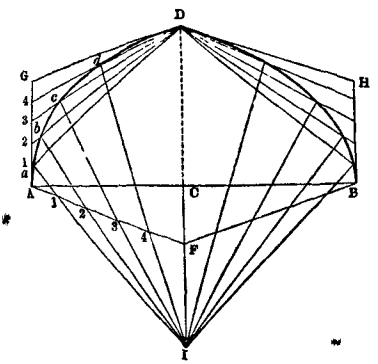

Fig. 624.

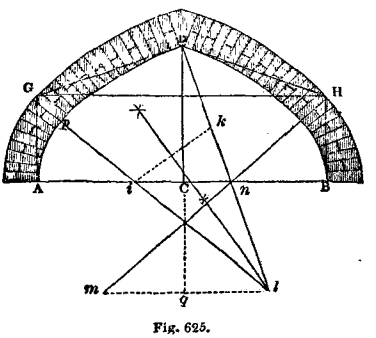

Fig. 625.

(CI is made equal to BC.)

AB equal in length to the span of the arch. Bisect AB in C by the perpendicular DI. and draw AG and BH parallel to DI. Make CD equal to the height of the arch, and the angles CDG and CDH each equal to half the vertical angle; make CF equal to the difference between CD and AG and join FA and FB. Divide AG and AF each into the same number of equal parts, counting each from the point A. Through the points 1, 2, 3, 4 in AF draw I*a*, I*b*, Ic, I*d*, and through the points 1, 2, 3, 4 in AG draw 1D, 2D, 3D, 4D cutting I*a*, I*b*, Ic, I*d* at the points *a*, *b*, *c*, *d*, then through the points A*abcd*D draw a curve; which will be half of the Gothic arch required. (Other methods, *par.* 1943*a*., *et seq.*)

1939. *To draw the joints of the arch stones of a Gothic arch* (*fig.* 625.). Having formed the angles CDG and CDH as before, make A*i* equal to AG and draw D*l* perpendicular to DG. In D*l* make D*k* equal to A*i* and join *ik*. Bisect *ik* by a perpendicular meeting D*l* in *l*. Produce *li* to *p*. Divide the curve into as many equal parts as the arch stones are to be in number. Then *i* will be the centre of the joints which pass through all the

points between A and p, and l will be the centre for drawing the joints of the arch stones which pass through all the points between p and D.

1940. The reason for the foregoing rule is obvious; for the joints are merely made to radiate to the centres of the arcs of circles whereof the arches themselves are formed; as in subsections 1934, 1935, they were drawn to the centres of the approximating circles wherefrom the elliptical curves were struck.

1941. *To describe a parabolic curve for a pointed or Gothic arch by means of a series of lines touching the curve, the dimensions of the arch and the angles it forms at the crown being given.* Draw the straight line AB (*fig.* 626.) and draw CD perpendicular to AB. Make CD equal to the height of the arch, CA and CB each equal to half the span. Make the angles CDe and CDf each equal to half the vertical angle. Divide Ae and eD each into the same number of equal parts, and through the corresponding points of division draw lines which will form one half of the arch: the other half DB may be found in the same manner.

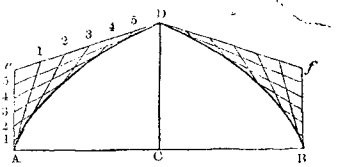

Fig. 626.

1942. *To draw the joints of the arch stones to the above sort of arch.* Draw the chords AD, DB for each half of the arch (*fig.* 627.); divide the arch into as many equal parts as there are to be arch stones. Let it now be required to draw a joint to any point h: bisect AD in k, and join ek cutting the curve in l. Draw hg parallel to Ak, cutting ek in g, and in el make li equal to lg. Join hi and draw hm perpendicular to hi. Then hm is the joint required. In the same manner all the remaining joints will be found.

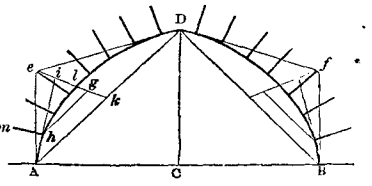

Fig. 627.

1943. *To describe a rampant pointed arch, whose span, perpendicular height, and the height of the ramp are given.* Draw the straight line AB (*fig.* 627.), and make AB equal to the span of the arch. Draw BC perpendicular to AB, and make BC equal to the height of the ramp. Bisect AC in D, and draw DE perpendicular to AB. Make DE equal to the height of the arch; draw Af and Cg parallel to DE, and make Af and Cg equal to about two thirds of DE. Join fE and Eg. Divide Af and fE each into the same number of equal parts, and through each two corresponding points of division draw a straight line. All the lines thus drawn will give one half of the curve. The other half may be drawn in the same manner. *To find the joints of the arch-stones to this sort of arch,* proceed as for a plain arch in the last example, as shown by *fig.* 629.

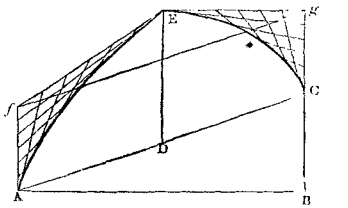

Fig. 628.

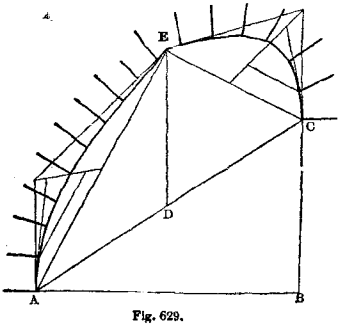

Fig. 629.

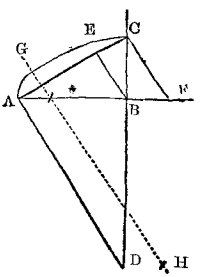

Fig. 629a.

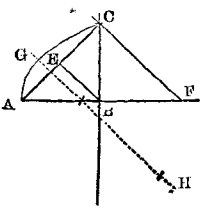

Fig. 629b.

1943*a*. Besides the rule given in *par.* 1938, *To draw a Gothic arch to any given dimensions*, the following plan has been put forward for finding the curves of arches and ribs. The fundamental rule that the curves should spring from the line of the impost has been abandoned by many; one centre was to be taken a little above this line, another a little below it, and so on. The following rule furnishes a principle which gives the centres of all these curves with perfect certainty and perfect harmony, at the same time furnishing

what is a further requisite, an independent projection for each rib. The author insists that these curves were always elliptical. If the arch to be drawn be *less* in height than the half width, let AB, (*fig.* 629*a.*) be the half width; BC the height; join AC; draw lines from B and A perpendicular to AC, and the points E and D are those required. Then EC will be the smaller radius, and EC added to AD will be the longer radius. For arches whose height is *greater* than their half width (*fig.* 629*b.*), draw CF and BE perpendicular to AC, then EC will be the smaller radius; and EC added to CF will be the longer radius. The author of this theory is Thos. L'Aker, as read at the Liverpool Arch. Society, 16th October, 1850, and printed in the *Civil Engineer*, vol. xiii. p. 365. See *par.* 2002*d.*

1943*b.* Although the term *arc en tiers point* is still used in France for an arch enclosing an equilateral triangle, as it was in the time of De Lorme, that architect, in his work entitled *Nouvelles Inventions pour bien bastir*, published in 1578, showed that the *arc en tiers point* was obtained by division of the space into three equal portions, of which two gave the radius. The *arc en quatre points* was obtained by division into four, three of them giving the radius. This mediæval mode of determining some of the shapes of pointed arches, was noticed by Professor Willis in his elucidation of Wilars de Honecort's *Sketch-book*, 1859, p. 138–40. He is disposed to call the equilateral arch, the arch of two points; mentions arches of six points; and instances cases with a radius of five-sevenths and a radius of five-eighths, besides the occurrence of a centre placed to the extent of half the span outside the springing point. The same authority observes that the true method was forgotten soon after the disuse of mediæval art, as Viola Zanini, in his book *Della Architettura*, published 1629, defines the *terzo acuto* as the arch on an equilateral triangle, the *quarto acuto* as the arch on a square with the diameter for radius, and the *quinto acuto* on a pentagon: these last are respectively rather higher and lower than the true arch of four points. The term *point* is here used as meaning a division, and not a puncture.

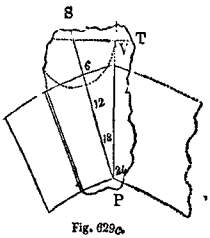

Fig. 629*c.*

1943*c.* The Professor has also explained, p. 141, that to know the extra length of a voussoir at the top of an arch of 2, 3, 4, or 5 points, the radius may be prolonged through the point P (*fig.* 629*c.*) of the arch to any extent S; then PS being divided into twenty-four parts, a line from S may be drawn parallel with the springing line to T, and respectively 12, 6, 8, or 9 of those parts in length; which will give a point V, so that PV will be the line of the central joint.

1943*d.* The construction of *ogee arches* is very simple; but as will presently be shown, the rule is open to judicious variation. The general principle is to draw the line of the nose Z, (*fig.* 629*d.*) of the hoodmould; to take a point upon that line; to draw from the springing a line through that point to the centre line, to accept the place where the centre line is cut as the height of the ogee, and to find in the usual manner the centre for the upper part of the ogee. The following directions are chiefly taken from Viollet le Duc, *Dict.*

1943*e.* *To draw an ogee arch of one point* (*fig.* 629*d.*). Bisect the span in D, draw the centre line CD, describe the arc AG, bisect AG in E, and through E from A draw a line cutting the centre line in H; through H draw FK parallel to the springing line, and through E from D draw a line cutting FK at M, which will be the centre for the upper part of the ogee arch. In some cases, as in the figures 629*e*, *f*, and *h*, the three points KMN form an equilateral triangle.

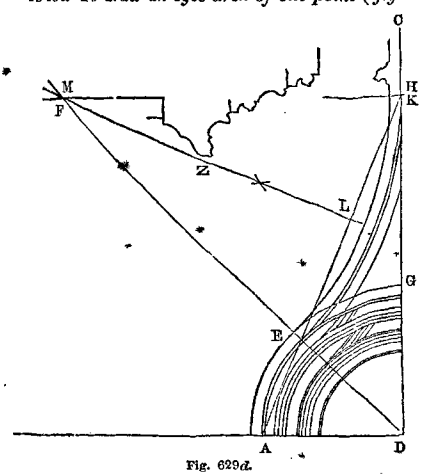

Fig. 629*d.*

1643*f.* *To draw an ogee arch of two points* (*fig.* 629*e.*). Bisect the span AB, draw the centre line, and describe the arcs AGB; then divide GB into five parts G1, &c., and proceed as before.

1943*g.* *To draw an ogee arch of three points* (*fig.* 629*f.*). Repeat the above operations, observing to divide the span AB into three parts, AE, EF, FB, and to divide GB into four parts, G1, &c. It will be observed that in *fig.* 629*g.* (from Pugin), AB is divided into three parts, and the centres E with F serve to describe the arcs on their own sides of the centre line; that the distances AI, II, and IB are equal, and that EH is equal to EI.

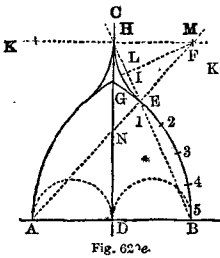

Fig. 629e.

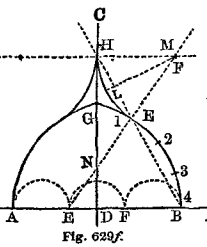

Fig. 629f.

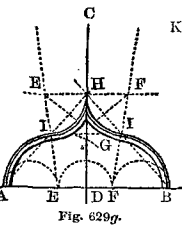

Fig. 629g.

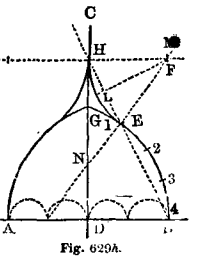

Fig. 629h.

1943*h*. *To draw an ogee arch of four points* (*fig.* 629*h*.). Bisect the span, draw the centre line, fix the four points, and describe the arcs AG, GB; then divide GB into *four* parts, and proceed as above indicated. But a difference is taught by an illustration adduced by Viollet le Duc, to show another feature of mediæval art. In *fig.* 629*i*. it will be observed that the arch GA is divided into *five* portions, and that the line AH is drawn through the second division. The line F2 produced, cuts the horizontal line JH in M; or 2H may be bisected, and a perpendicular obtained meets in the point M, for the ogee line 2H. A centre N has been assumed for the line RR; and also another centre, O, for the line PP, both lines being drawn each way from I; from which arrangement it results that the lines A2H, RIR, and PIP, are not parallel for their whole lengths. In some cases the line of work must be the centre of a fillet or of a boltel. It should be noticed that some very good decorated work of the middle of the 14th century, uses five-eighths of the space for the radius, and finds the centre of the ogee curve upon a line drawn from that central point of radius at an angle of 45° with the horizontal springing line.

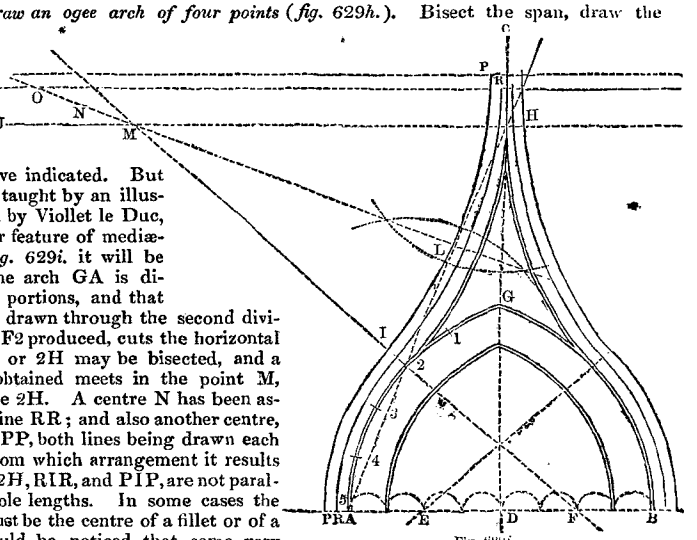

Fig. 629*i*.

1943*i*. *To draw a cusped ogee arch* (*fig.* 629*k*.). Proceed as above described for an arch of one point as far as the construction of the horizontal line JK. Then from the centre F through E draw a line, and thereon make IU equal to IS, being so much of IF as is intercepted by the centre line of the pointed arch; and then on the horizontal line JK make WH equal to IS: thus are obtained the two centres for the cusp. But Viollet le Duc appears to prefer another mode, which very slightly differs in result. He draws SI produced at an angle of 45° with the base line; on this he marks G′U, which is the half of a semicircle, equal to GA, fixing IU, and continuing the process as in the former method.

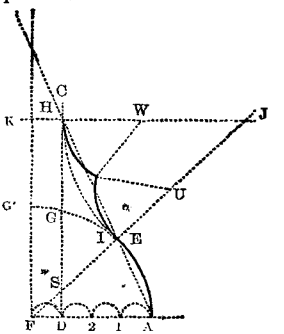

Fig. 629*k*.

1944. II. Of the Construction of intersecting Vaults or Groins. The forms of vaults may be so adapted to one another that the lines of intersection shall be in planes, and these planes the diagonals of the plan of the intersecting part of the vaults; if, however, they be not so adapted, the lines of intersection will be curved on the plan, and these curves it is necessary to ascertain in making both the moulds and the centerings for executing the work.

1945. *To determine the form of a vault to intersect with a given one in the plane of the diagonal, and also to find the diagonal rib for the centering.* Let the given vault be EIF (*fig.* 630.) and AC and BD the diagonals, crossing in *f*. Draw *f*I perpendicular to EF, cutting EF in *c*. In the arc IF take any number of points *ab*, and draw *ag*, *bh* parallel to If, cutting EF in *d*, *e*, and the diagonal AC in *g*, *h*. Draw *fp*, *gq*, *hr* parallel to EF, cutting the base GH at *m*, *n*, *o*. Make *mp*, *nq*, *or*, each respectively equal to *c*I, *da*, *eb*. Draw *f*I′, *gk*, *hl*, perpendicular to AC, and make *f*I′, *gk*, *hl* respectively equal to *c*I, *da*, *eb*. Make

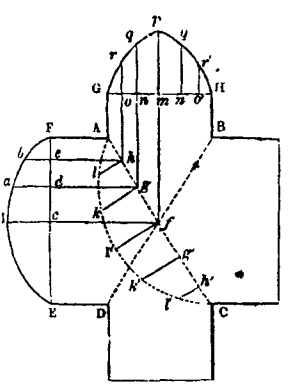

Fig. 630.

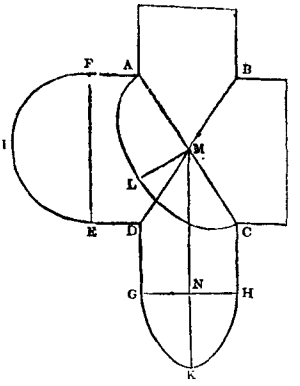

Fig. 631.

fg', *fh'* each respectively equal to *fg*, *fh*. Draw *g'k'*, *h'l'* parallel to *fI'*. Make *g'k'* equal to *gk*, *h'l'* equal to *hl*; also make *mn'*, *m'o'* each respectively equal to *mn*, *mo*. Draw the arcs *pqr*, *p'q'r*, as also *l'kl*, *l'k'l'*; then, through the points thus found, draw the curves upon their bases AC and GH, and that on GH is the form of the intersecting vaults, and that on AC is the form of the angle rib. If the form of the given arch be that of a semicircle EIF (*fig.* 631.), let ABCD be the angular points of the plan, AC and DB the diagonals, cutting each other at M. Draw MK parallel to GD, or CH cutting GH in N. Draw ML perpendicular to AC, and make ML equal to the radius of the semicircle. Then, with the transverse axis AC, and semi-conjugate axis ML, describe a semi-ellipse, which will be one of the angle ribs, as required. Also make NK equal to the said radius; then with the lesser axis and the semi-greater axis NK describe the semi-ellipse GKH, which is the form of the other vault.

1946. The same method applies in *fig.* 632., where the narrow opening is a semi-circle

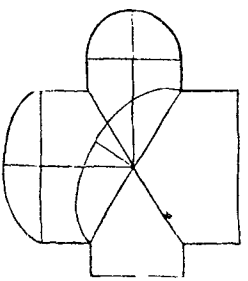

Fig. 632.

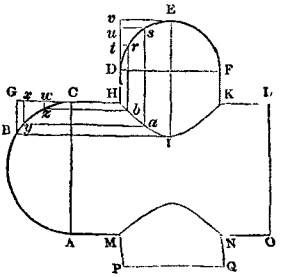

Fig. 633.

and the wide one, consequently, a semi-ellipse, having its minor axis vertical and its major axis horizontal.

1947. *When two circular-arched vaults of different heights intersect, to determine the plan of the arrisses in which the arches meet.* Let ABC (*fig.* 633.) be the arch of the main vault, and DEF that of the lesser vault; ACLO the plan of the main vault, and DPQF that of the lesser vault; and let the two vaults intersect each other at the points HKNM. Also, let E be the middle point of the lesser semi-circular arc DEF. Produce HD to *v*, and in the arch DE take any number of points *rs*, and draw *rb*, *sa*, EI parallel to DH. Draw *rt*, *su*, Ev parallel to DF, cutting D*v* at the points *tu*, and produce HC to G. In CG make C*w*, C*x*, CG respectively equal to D*t*, D*u*, D*v*, and draw *wz*, *xy*, GB parallel to AC, cutting the semi-circle ABC in the points *zy*B. From the points B*yz* draw BI, *ya*, *zb*, parallel to CL. Then through the points I*ab* draw a curve, which will be one half of the plan of the arris. The other half will be found in the same manner.

1948. The method of tracing the plan of the groins is the same (see *fig.* 634.) when the vaults intersect obliquely.

1949. *To find the plan of the intersections of two arches of the same height, and either of the same or different species.* Let the sections of the two arches be ABC and DEF (*fig.* 635.), the arcs AB, BC being equal to each other, and the arcs DE, EF equal to each other;

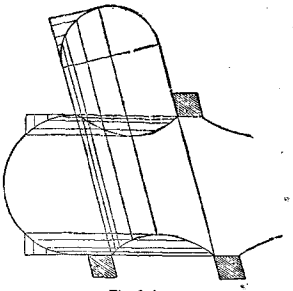

Fig. 634.

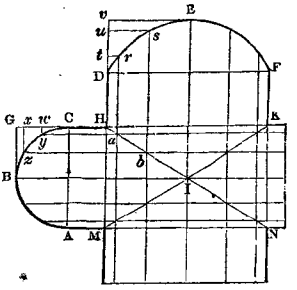

Fig. 635.

and let H, K, N, M be the points where the two arches intersect each other on the plan. Divide either of the arcs BC or DE into parts, equal or unequal; as, for example, in the arc DE take any number of points *r, s* at pleasure, and draw *ra, sb*, EI perpendicular to DF. Produce HD to *v*, and draw *rt, su*, Ev, parallel to DF, cutting Dv in *t, u, v*. Produce HC to G, and make C*w*, C*x* respectively equal to D*t*, D*u*; and as the arches are equal in height, CG will be equal to D*v*. Draw *wy, xz*, GB, parallel to AC, cutting the arc BC in the points *y, z*, and touching it in B. Draw *ya, zb* and BI parallel to HK, and through the points H*ab*I draw the curve H*ab*I, which will be half the plan of the groin as required. The other half IN and the other groin MK will be found in the same manner.

1950. *To find the plan of the groins produced by the intersection of a cylindric and a conic vault, the angle of position of the axis, the diameter of the cylinder, and the plan of the conic vault being given.* Let AB (*fig.* 636.) be the axis of the cylinder, CD that of the cone, C being the apex, and D the point through which the base passes. Through any point A in AB draw EF perpendicular to AB, and make AE and AF each equal to the radius of the cylinder, and draw EH and FI parallel to AB. Through D draw KM perpendicular to CD, and make DK and DM each equal to half the diameter of the cylinder. Join KC and MC, cutting EH and FI in the points N, O, P, Q. Divide the semicircles FGE and KLM into parts, whereof the corresponding ones are equal to one another. From the points of division in the semicircle EGF draw lines parallel to AB; and through the corresponding points in the semicircle KLM draw lines perpendicular to the diameter KM, cutting KM. From the points of section draw lines to the apex C of the cone, cutting the former drawn through the points in the semicircumference FGE. Through each set of corresponding points draw a curve, and the two curves will represent the arrisses of the groin on the plan. If in an octagonal ground vault the octagonal range be cylinders, and the cross vaults, which tend to the centre, diminish to a line of the height of the vault, the following construction applies: — Let EFGHI (*fig.* 637.) be the exterior side of the vault, which is both equilateral and equiangular, and let JKLMN be the line of the exterior surface of the inner wall; so that the lines EJ, FK, GL, HM, IN, which pass through every two corresponding angles, may tend to the centre O of the groin vault. Let the sections of the given ribs be PQR and STU, so that PR of the rib PQR may stand at right angles to the sides EF and JK, and the side SU of the rib STU on the middle of the side FG. Divide the two bases PR and SU in the same proportion, and through the joints of division in SU draw lines from the centre O of the ground vault to meet the curve STU; and

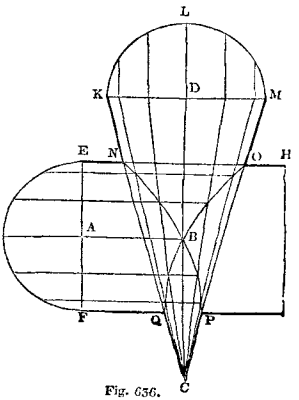

Fig. 636.

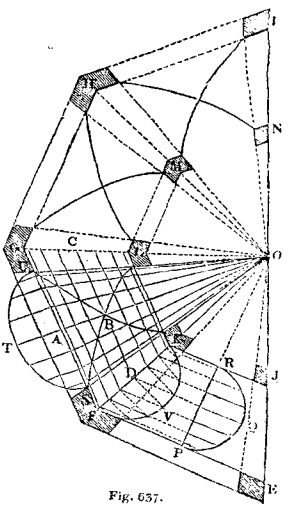

Fig. 637.

through the points of division in the base PR of the cross rib PQR draw lines parallel to EF, to terminate in the line FK, and in the semicircle PQR. From the points where these lines meet FK, draw perpendiculars on one side of FK, and make the heights of these perpendiculars respectively equal to the ordinates of the arc PQR; and through the ends of these perpendiculars draw a curve FVK, which will be the angle rib. From the points of meeting in the line FK draw lines parallel to FG, and through the points of division in SU draw lines to the centre O, intersecting the former lines drawn from the points of division in FK; through the corresponding points of intersection draw the curves SBL and KBU, which will form the plan of the angle.

1951. In single groins the centres are made for the widest avenue, and are covered over with boards (*fig.* 638.), so that the top of the boards may form the surface required for

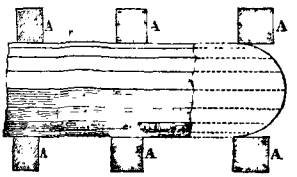

Fig. 638.

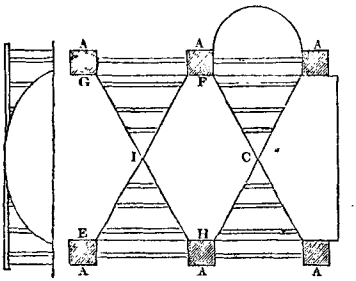

Fig. 639.

turning the arch upon the intersections; or the angles are found by the following practical method. The groins meet in the points I, C (*fig.* 639.), upon the boarding of the two groins. Place the straight edge of a board upon the point I, so as to range over the line GH on the plan. Then set up another straight edge upon the point H, so as to be vertical, and the straight vertical edge will meet the horizontal edge; then apply a third straight edge to each of the other two straight edges, so that it may also come in contact with the boarding. After this draw a line along this third straight edge upon the boarding as far as may be found convenient; shift the moveable or third straight edge, and apply it in the same manner to another adjoining portion of the surface of the boarding. Proceed in the same manner until the whole line be completed on the surface. By this means, the necessity of laying down lines for the covering is avoided. The lines being thus drawn, ribs for the cross vaults are fixed on the top of the boarding; so that, making proper allowance for the thickness of the same, its surface, when fixed, may form the true surface of the other cross vault. The ribs fixed upon the boarding to form the cross vaults are called *jack ribs*.

1952. The mode of constructing the curves by lines is shown for a rectangular groin in *fig* 640., in which A is the plan, B the elevation. Here, to find the pliant moulds for forming the groins on the surface of the boarding, and working the arch-stones, describe a semicircle on one of its sides, and divide it into any convenient number of equal parts. Draw lines perpendicular to the base or diameter, the semicircle being supposed to be within the piers; the ordinates will cut the diagonals; but if it be laid down on the outside, the ordinates must be produced until they cut the diagonals. From the points where the ordinates cut the curve, draw lines parallel to the other side of the groin, and produce the side on which the diameter of the semicircle is placed, and extend the semicircular arc with its divisions upon any convenient part of the line thus produced. Through the points of division draw perpendiculars, so as to intersect with the former parallel lines; then through the points of intersection draw the curve, as shown at C, which will be the mould required.

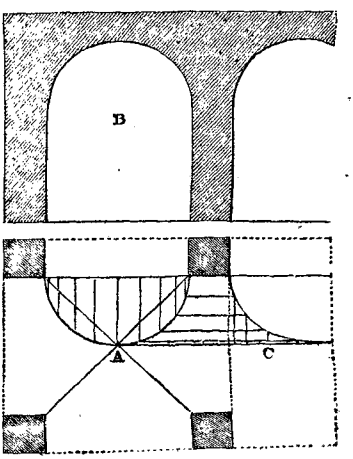

Fig. 640.

1953. Sometimes several vaults meet in one common centre, as in *fig.* 641., which exhibits the plan of an equiangular and equilateral groined vault, constructed of semicircular arches.

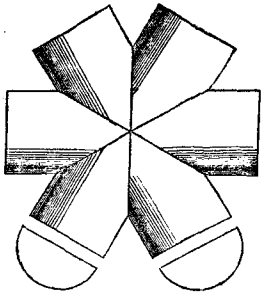

Fig. 641.

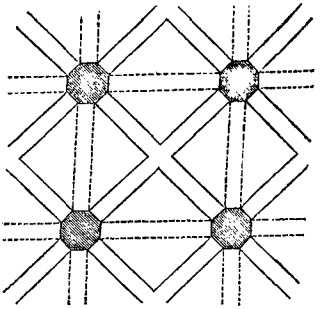

Fig. 642

1954. Where the piers supporting groins (*fig.* 642.) are made octangular, the angles of the groins should be cut off or arched as ribs, by which they are rendered much stronger than when they are square. In stone groins, where the arch is cut off, there is no advantage in point of strength, and rather a defect in point of appearance, to the groined angles.

1955. Arches intersecting a coved ceiling are similar to groins. Such arches are called *lunettes*, and are generally practised for semicircular-headed windows piercing the coves in the ceiling: *fig.* 643. exhibits a plan and section of such arches.

1956. A dome is a solid, which may be conceived to be generated by the figure of the base diminishing as it rises, till it becomes a point at the summit; and when a dome has a polygonal base, the arches are plain arches, and the construction is similar to that of a groin. A domed ceiling of this kind upon a rectangular plan is shown in plan B (*fig.* 644.); the sections AA being elliptical in the top, and with lunette windows. C shows the geometrical construction.

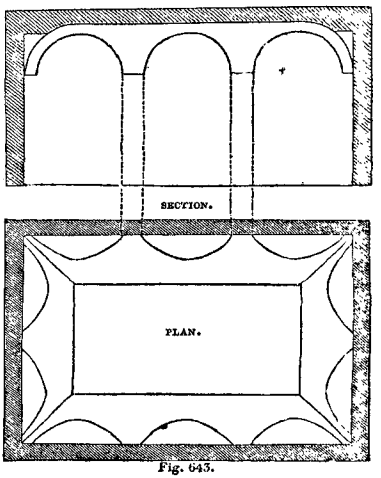

Fig. 643.

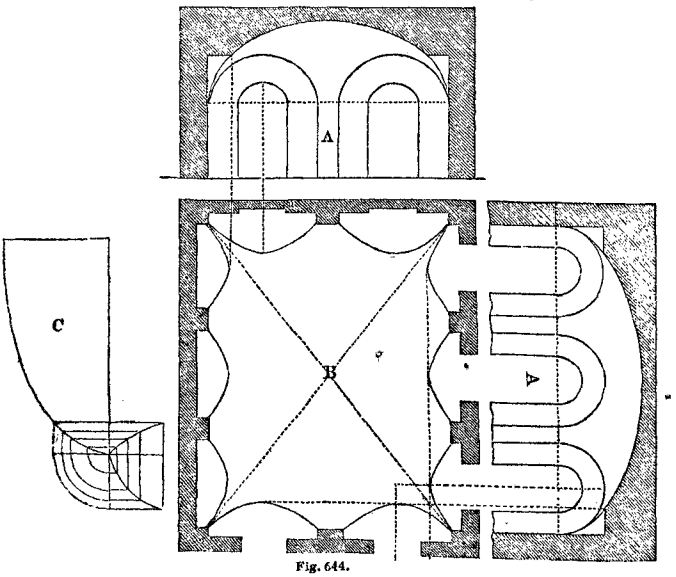

Fig. 644.

1957. *When arches intersect an inclined vault, and the projections of the arrisses cross each other at right angles, and the angle of elevation of one of the semicircular vertical ribs of the ascending avenue or opening is given to obtain the geometrical construction; so that the cross arches may be cylindrical surfaces.*

Draw the straight line AB (*fig.* 645.) to represent the axis of the inclined vault, and draw CD perpendicular to AB. Produce CD to *e* and *k*; make AC and AD each equal to the radius which forms the edges of the ribs; draw *k*N parallel to AB, and make the angle N*ko* equal to the inclination of the axis represented by its plan AB. In the line *ko* take any point *p*, and draw *qp* parallel and *ps* perpendicular to *k*N. Make *ps* equal to AC or AD, and through *s* draw L*t* parallel to *ko*. Draw *pu* perpendicular to L*t*, cutting it in *u*. Produce *pu* to *v*. Set the circumference of the inclined vault from *u* to *v*, divided into the equal parts *u*, 1, 1, 2; 2, 3; 3*v*, at the points 1, 2, 3. Divide each of the quadrants *qs*, *sr*, into the same number of equal parts at the points 1, 2, 3, and through these points and in *uv* draw 1*a*, 2*b*, 3*c* parallel to *vt*, and through the points 1, 2, 3, in the curve *qs*, draw *i*L, 1*a*, 2*b*, 3*c*, parallel to *pu*. Through all the points L, *a*, *b*, *c* draw the curve L*abcv*, and this will be the pliable mould for forming the angle or groin over the plan, and for working the arch stones. Draw D*k* parallel to A*z*. Let E divide the circumference CED into the two equal parts EC, ED; divide the arcs DE, EC into the same number of equal parts as *uv* at the points 1, 2, 3, and draw 1*w*, 2*x*, 3*y*, E*z*, parallel to AB; also through the points 1, 2, 3 in the quadrant *qu* draw *gk*, 1*w*, 2*x*, 3*y*, *uz*, perpendicular to *y*N; then through the points *k*, *w*, *x*, *y*, *z*, draw a curve, which will be the plan of the groin whereof the stretch-out is L*abcv*. In the same manner the other half of the plan will be found, as also the whole of the other parts.

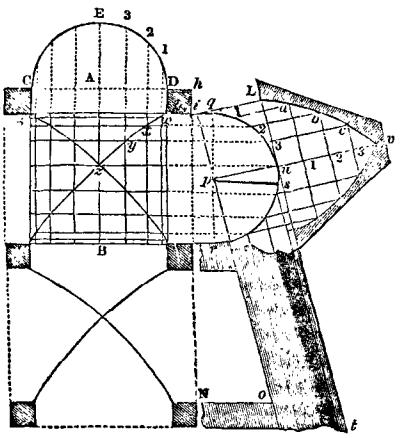

Fig. 645.

1958. *The form of an arch crossing an inclined groined vault at right angles, and the plan of the diagonal ribs being given; to find the arch of the level vault.* Let AB, BC (*fig.* 646.) be the plan of the axis of the vaults. Through any point A in AB draw DF perpendicular to AB, and make AD and AF each equal to the horizontal breadth of the vault. Draw DG and FH parallel to AB; draw also any line LK parallel to AB, cutting BC in C, and make the angle KIL equal to the inclination of the axis represented by its plane AB. Make CM and CK equal to the breadth of the level vaults; draw KG and MN parallel to BC, and let MN cut DG in N, and FH in P. Draw the diagonals PG and NH. Produce GK to cut IL in L, and NM to cut IL in Q. In the curve DEF take any number of points *a*, *b*, *c*, and draw *ad*, *be*, *cf* parallel to AB, cutting DF in the points *p*, *q*, *r*, and the diagonal GP in *d*, *e*, *f*, and the diagonal HN in the points *d'*, *e'*, *f'*. Produce BA to E, draw *dl*, *em*, *fn*, Bo parallel to BC, cutting QL in the points *g*, *h*, *i*, *k*; make *gl*, *hm*, *in*, *ko* equal respectively to *pa*, *qb*, *rc*, AE; then through the points *l*, *m*, *n*, *o*, draw the curve QoL. Draw HR perpendicular to NH, and make HR equal to KL, and join NR; then will HR be the line of ramp for the diagonal rib over its plan HN. Perpendicular to HN, draw *d'v*, *e'w*, *f'y*, BG cutting the line of ramp RN in the points *s*, *t*, *u*, *v*. Make *sv*, *tw*, *uy*, *v*G respectively equal to *pa*, *qb*, *rc*, AE. Then through all the points *v*, *w*, *y* draw a curve, which will be the angle rib standing over HN, and which will also serve for the angle rib standing over GP. All the groined vaults continued in the same range may be constructed by the same moulds.

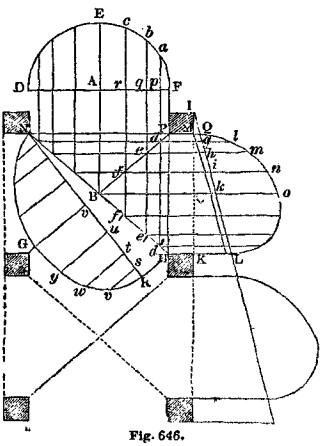

Fig. 646.

1959. *To make the working drawings for a semicircular arch with a straight face, and to describe the moulds for the voussoirs.* This simple case will serve as a rule for those following; hence the explanation should be perfectly understood, as all the other cases differ

from it only according to the different kinds of arches to be constructed; such as the *bevelled arch*, that in a *battering* or *sloping wall*, and that on a *circular wall*.

1960. Draw two lines (*fig.* 647.) perpendicular to and crossing each other, as BA, GD From the point E, as a centre, describe the sofite curve ACB, and the extrados or upper curve FGH. Divide each of these arcs into two equal parts, as the dotted arc *abc*. Draw LM parallel to AB, and make the distance A′ L equal to the thickness of the wall wherein the arch is to be constructed. Draw the outer and inner lines of the plan F′K, A′L, B′M, HN parallel to CD. Divide the arc ACB into the proper number of equal parts for the arch stones or voussoirs, suppose five, by the joint lines 1, 2, 3, 4; from the point E draw the joints 1—5, 2—6, 3—7, 4—8; then from every point where the joints cut the arcs ACB, FGH, &c. draw the perpendiculars cutting the line KN, as 8*d*, c M, 4*f*, 7*g*, *hi*, 3*k*, 2*l*, *mn*, 6*o*, *p*, *a* L, and 5*s*. Divide the sofite of each voussoir A1, 1—2, 2—3, &c. into two equal parts *t*, *u*, *v*, *w*, from which also let fall the perpendiculars *t* Y, *u* X, *v* V, *w* T.

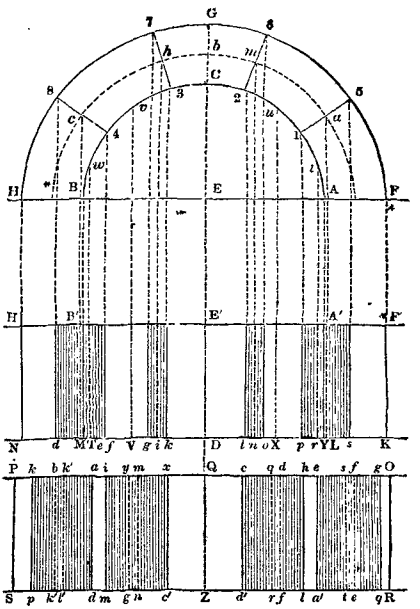

Fig. 647.

1961. *To draw the moulds of the sofite* below NK. Draw the line OP parallel to the line KN; prolong ED to Z and make the distance QZ equal to ED. Through Z draw RS parallel to OP, and on each side of QZ lay off the distances C3, 3*v*, *v*4, 4*w*, and *w*B respectively on Q*x*, *xy*, *ya*, *ab*, and *b*P. On the other side lay off C2, 2*u*, *u*1, 1*t* and *t*A on Q*c*, *cd*, *de*, *ef*, and *f*O. Through the points O, *e*, *c*, *x*, *a* let fall on RS the perpendiculars OR, *ea′*, *cd′*, *xc′*, *ad*, PS, and through the points *f*, *d*, *y*, *b* let fall the perpendiculars from the middle sheetings *fe′*, *df″*, *yg′*, *bh′*; the distances of the dark lines give the breadth of the sofite of each stone in the sofite curve.

1962. *To draw the moulds of the joints:* lay off the distance 1 — 5 on *eg*, *ch*, *xi*, *ak*, and through the points *ghin* draw the lines *gq*, *hl*, *im*, *kp*, parallel to QZ. To find the middle of the joint divide the distances *eg*, *ch*, *xi*, *an*, each into two equal parts, as in *k′*, *m′*, *g′*, *s*, through which draw the lines *k′l′*, *m′n′*, *q′r′*, *s′t* parallel to QZ.

1963. The elevation is a section of a hollow cylinder, of which the concave or interior surface forms the intrados of the arch, and the convex or exterior surface the extrados, and of which the cutting plane of the section is perpendicular to the common axis of the cylinder.

1964. The angles of the stone are found from the angle which the arc of this section makes with any joint, and the curving of the sofite of the stone is found by a ruler or mould, the edge of which is made to the curve. The ends of the sofite are found by its developement.

1965. When the stones are shaped according to the moulds, and joined together in consecutive order, the whole mass, thus united, will form the solid arch as required.

1966. These separate operations being properly attended to, every difficulty will be removed, and no confusion will arise during the process, which can, in any degree, tend to perplex the delineator.

1967. *To find the bevels and moulds for the joints and sofites of an elliptical arch cutting obliquely through a straight wall, the joints radiating to the centre of the opening.* Draw the axis EN of the arch (*fig.* 648.), and therein take any point E, through which draw AB perpendicular to EN; make EA and EB each equal to half the space of the extrados or centre line of the arch; also make EC and ED each equal to half the span of the inner arch. Produce the diameter NE to G;

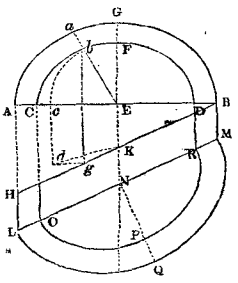

Fig. 648.

make EF equal to the height of the inner arch and EG equal to the height of the outer arch. On the major axis AB, and semi-minor axis EG, describe the semi-ellipsis AGB, which is the extrados of the arch. Also, on CD as the major axis, and EF the semi-minor axis, describe the semi-ellipsis CFD.

1968. Make the angle ABH equal to the angle which the wall makes with the right section of the arch, and let BH cut the axis in K. Draw ML at such a distance from BH that they may comprehend between them the thickness of the wall, and let ML cut the axis in N. The intrados of the arch on the one side of the wall is OPR, and the extrados is LQM; they are both ellipses respectively of the same height as the intrados and extrados of the right arch, but with the axes OR and LM.

1969. *To find the bevel of the angle of the arch stones corresponding to the joint ab tending to the centre* E. Describe the arc *bc* from E with the radius E*b* cutting AB in c. Draw *bg* parallel to EN cutting BH in *g*, and draw *cd* parallel, and *gd* perpendicular, to EN, and join K*d*: then EK*d* is the angle or bevel required (*fig.* 648.)

1970. The sofite of the arch is drawn according to the general principles of developement

1971. *To make the working drawings for an arch in a sloping wall, as, for instance, an arch in a terrace wall.* To draw the elevation; from any convenient point *o* in the line AB (*fig.* 649.), describe the arc of the intrados *a*P*f* and the arc of the extrados AQB: divide each of these arcs into odd numbers of equal parts (for the arch stones in this example five), and draw the joints *bg*, *ch*, *di*, *ek*. For the plan of the arc of the intrados draw AR perpendicular to AB, and draw the line of slope or *batter* AS. In the arc of the intrados take any number of points *bcd*, &c. and draw the lines *bb*, *cc*, intersecting AR in the points 1, 2, &c. and meeting the line of batter AS in the points *bc*. Draw CD parallel to AB, and at any convenient distance from it draw *aubvcw* perpendicular to CD, intersecting it in the points *e*, *l*, *m*, *n*, &c. Find the points *b'*, *c'*, *d'* in the straight lines *bv*, *mw*, *nx*, such that the distance of those points from the line ED may be respectively equal to the intervals 1*b*, 1c, &c. between the perpendicular AR and the line of batter AS, and draw the curve *a' b' c' d' e' f'*, which will be the plan of the arc of the intrados. In the same manner the curve E*g'h'ik*D may be described; which being done, the plan of the arc of the extrados will be obtained.

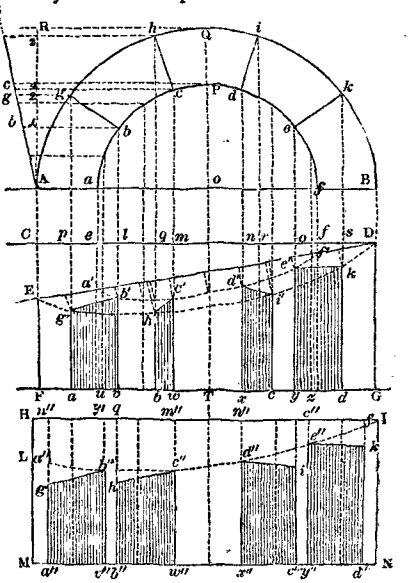

Fig. 649.

1972. *To find the moulds of the sofites and beds.* Draw any straight line HI in a separate place, and extend the arc of the intrados *abedef* upon the line HI from H to I; divide it into the same number of parts that the arc *a*P*f* of the intrados is divided into (in this instance five), and mark the points of division *l'*, *m'*, *n'*, *c'*. Transfer the distances *ea'*, *lb'*, *mc'* between the line CD and the plan of the arc of the intrados, to the perpendiculars *n''a''*, *l''b''*, *m''c''*, *n''d''*, *c''e''*, and through the points *a''b''c''d''e''f''* draw a curve, which will be the developement of the arc of the intrados. Produce the lines *l''b''*, *m''c''*, *n''d''*, to *v''*, *w''*, *x''*, and transfer the distances *b'v*, *c'w*, *d'x* from the plan to the sofite on the lines *b''v''*, *c''w''*, *d''x''*. Draw *ga''*, *hb''*, *ic''*, *kd''* perpendicular to HI; transfer the distances *g'a*, *h'b*, *i'c* from the plan to the sofite upon *ga''*, *hb''*, *ic''*, and join *a''v''*, *b''w''*, *x''c''*, which will complete the moulds of the joints.

1973. *To make the drawings for an oblique arch by an abridged method.* The following method is said to be abridged, because, by one very short operation the moulds of the sofites and joints are found within the plan of the arch ABDC (*fig.* 650.). "Divide AB in E into two equal parts, and draw EF parallel to AG. From the point A draw AG perpendicular to AC; prolong DB to G; divide AC into two equal parts in the point H. From H, as a centre, describe the arc AFG, which divide into voussoirs, and draw the joints from the centre H. Draw lines from each sofite parallel to EF, and below the line CD; the moulds for the sofites are comprised between the parallels of the key, and those of the joints are traced on the sides of the plan, as follows: —

1974. *To find the moulds of the sofites.* Through the point Q draw QN parallel to GH. To find on RS the point N, through the point K draw KL also parrallel to GH. To find on QT the point M, and on RS the point L, draw the front line of the second sofite

MN, and the front line of the first IL. The back of this sheeting sofite is found by the same operation below the plan. The mould of the key is formed by two lines RS, QT, and the front and back lines of the plan AB, CD; the two moulds of the sofites NMTS and LIXV serve to trace the two stones on each side, observing only that the lower arrisses of the sofite on the side AC become those of the top on the side BD; or that the under arriss of one side may be that on the other side by reversing the mould, which will have the same effect.

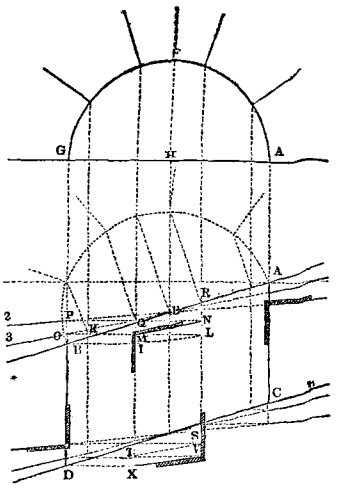

Fig. 650.

1975. *To find the moulds of the beds or joints.* Prolong NQ to meet DG, to find the point P, and through it and the point E draw the front of the second joint P2; prolong LM to GD to find O, through which and the point E draw the front of the joint O3. Proceed in the same manner to find the backs of the other joints, which are sufficient also to trace the stones by reversing them. It is not absolutely necessary to cut out the moulds of the sofites and joints, but the angles may be taken by bevels and applied to stones. The heads are prepared, as usual, with the moulds of the heads of the straight arc. It must be observed, that in this arch the face or front differs from a straight arch, being formed by different sections of a cylinder.

1976. *To find the moulds for an oblique arch, whereof the front slopes and the rear are perpendicular to the axis.* Let A′B′GH (*fig.* 651.) be the plan of the imposts. From the point *a*, as a centre, describe the arcs ACB, DRI, which divide into five or more equal parts for the arch stones. Draw the joint lines from the centre, and the perpendiculars from the joints below the line AB. From the summits of the perpendiculars, draw lines parallel to AB, to terminate in the perpendicular DF. From the point D, as a centre, describe arcs from the points which terminate in DF, to meet the line of slope DE in the points *m*, *l*, *k*, E. Draw the lines *mr*, *ls*, *kt*, EF parallel to AB, meeting the perpendicular DF in the points *rst*F; transfer the distances *rm*, *th*, *u*P from *n* to *b*′, from *o* to *c*′, from *a*′ to *s*′, and through the points A′*b*′*c*′*d*′*e*′B′ draw the curve. Find the extrados or outer line D*fghi* in a manner similar to that in which the inner curve has been found. Draw the points *b*′*f*′, *c*′*g*′, *d*′*h*, *e*′*i*. Prolong AH and BG to K and L, and draw the lines *b*′*b*, *c*′*c*, *d*′*d* parallel to AK.

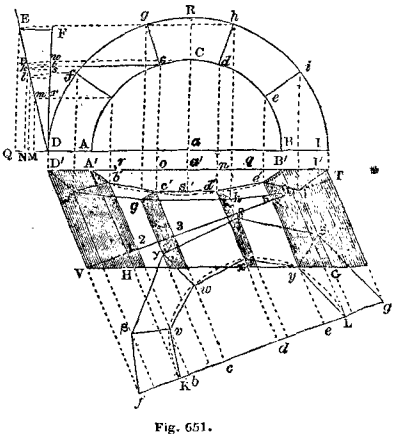

Fig. 651.

1977. *To make the straight arches.* Draw KL perpendicular to A′K, and produce KL to *f*′ and *g*′. Transfer the distances between the points *m*, *l*, *k*, E, and the line QD to the ordinates of the lower arc from *b* to *v*, from *c* to *w*, from *d* to *x*, and from *e* to *y*, and draw the curve K*vwxy*L. Also find the outer curve in the same manner, and draw VT at right angles to AH.

1978. *To find the moulds of the sofites.* Draw the line WX (*fig.* 652.) in any convenient surface, and lay the breadths of sofite, not from the arc ABC as before, but from those of the right arc K*vwxy*L, that is, transfer the distance K*v*, *ww*, *wx*, *xy*, *y*L to the line WX upon W*a*, *ab*, *bc*, *cd*, and *d*X. Through the points W*abcd*X, draw the lines *dy*, *ei*, *fk*, *gl*, *hm*, *yz*, perpendicular to

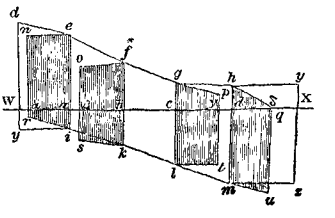

Fig. 652.

WX. Transfer the distances 1 A, 2*b'*, 3*c'*, 4*d'*, 5*e'* upon the perpendiculars to WX: that is, from *a* to *e*, from *b* to *f*, from *c* to *g*, from *d* to *h*, and from X to *y*, and join *de*, *ef*, *fg*, *gh*, *hy*. In the same manner draw the line *yiklmz*, which will complete the sofites.

1979. *To find the moulds of the joints.* Transfer the distances *vβ*, *wγ*, *xδ*, *yε*, to the line XW from *a* to *α*, from *b* to *β*, from *c* to *γ*, and from *d* to *δ*, and through the points, *α*, *β*, *γ*, *δ* draw the lines *nr*, *os*, *pt*, *δu* perpendicular to WX. Find the points *n*, *o*, *p*, *q*, as also, *r*, *s*, *t*, *u*, as in the preceding examples: then the moulds of the joints will be *eirn*, *fkso*, *ptlg*, *hδum*. It must be observed that the boundaries, or extrados and intrados, DRI, ACB of the ring of the arch, do not stand in a plane perpendicular to the plan, but are supposed to be the lines which are drawn on the wall itself; and this is the reason why arcs are described between the perpendiculars DF and the line of slope DE. It must also be observed, that the voussoirs of this arch must be cut by the moulds of the heads of the straight arch, and the moulds of the sofite must be applied on the voussoirs before the sofite is hollowed. Thus, let the first voussoir on the right hand be cut by the head mould on that face of the stone intended for the sofite; apply the first sofite mould, and its upper bed the first joint mould, and on its under bed the plan of the impost. Then cut the two heads according to these moulds, and hollow the sofite square to its arrisses, using for this purpose the curved bevel.

1980. *To find the moulds for executing a semicircular-headed arch in a mass of masonry, of which one of its faces is a battering plane upon an oblique plan, and the other opposite face a portion of a cylindric surface.* Describe the intrados and extrados of the elevation; draw the joints and describe the plan *a'b'c'd'e'f'* of the intrados (*fig.* 653.), and the plan *Eg'h'i'k'* D of the extrados. Draw BR perpendicular to AB, and draw BS', the portion of the cylindric surface. From the arc BS' draw the plan *a'l'm'n'o'f'* of the intrados upon the line TU, and the plan *Tp'q'r's'U* of the extrados in the same manner from the arc BS, as the plan of the plane face was drawn from the line of slope AS.

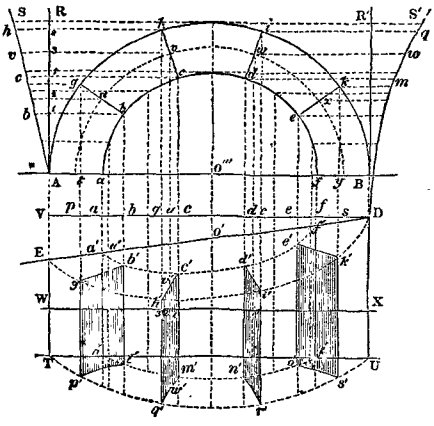

Fig. 653.

1981. *To find the plan of any joint*, as that for the line or joint *ch* in the elevation. Bisect *ch* in *v*, draw *cm'*, *vw'*, and *hq'* perpendicular to AB, intersecting the line VD in the points *quc*. From the points *cvh*, in the joint *ch*, draw *cc*, *vv*, *hh*, meeting the line AS in the points *cvh*, and intersecting the line AR in the points 1, 3, 2 by three intervals, 1*c*, 3*v*, 2*h*. Find the places *hvc* of the three points *hvc* on the elevation. In the same manner find the places *q'w'm'* of the three corresponding points; then will *c'v'h'q'w'm'* be the plan of the joint required. The plans of the other joints will be found in the same manner.

1982. *To find the joint mould itself.* Draw the line HI (*fig.* 654.) equal in length to the developement of the intrados, and let Hc be the developement of the arc *ac*; draw *cm''* perpendicular to HI. Draw any line WX in the plan parallel to VD, intersecting the lines *c'm'*, *v'w'*, *h'q'*, in the points 1, 2, 3. Draw W'X' in the developement or sofite parallel to HI, and at the same distance from HI that WX is from VD in the plan, and let WX intersect the line *c''m''* in 1. Make the distances 1—2, 2—3 respectively equal to *cv*, *vh*, in the joint *ch* in the elevation, and through the points 1, 2, 3, just found, draw VW, *h''q''*, parallel to C'*m''*. From the plan transfer the distances 2*v'*, 2*w'*, 3*h'*, 3*q''* to the sofite from 2 to V, and from 2 to W; also from 3*h''* and from 3 to *g* the points *cvp''* will be in a straight line, because they correspond to the straight face of the wall, and the points *m''*, *w*, *q''* will be in a curve, because they correspond to the cylindric surface. Draw, therefore, the straight line *c''h''*, and draw the curve line *m''wq''*, which will be a portion of an ellipsis, differing in its curvature but in a very small degree from that of a circle drawn through the same three points. However, if more exactness be required, we may find as

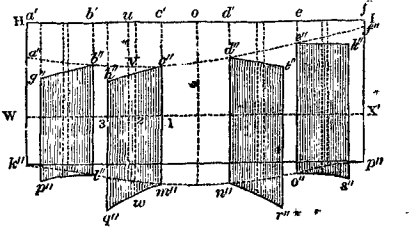

Fig. 654.

many points in the joints of the surface of the wall and in the cylindric surface as we please; then $c''m''p''h''$ is the joint required, which serves for the upper and under beds of the two stones that unite together in that joint.

1983. Find all the other joint moulds $b''l''p''g''$, $d''n''v''t''$, $e''o''s''k''$, in the same manner, and find the points $a''f''$ in the developement. Through the points $a''b''c''d''e''f''$ draw a curve line by hand, or by a ruler bent to the points, and this will be the front curve of the sofite. Find the points $k''p''$ in the developement corresponding to the points a' and f on the plan, and through the points corresponding to the points a' and f on the plan, and the points $k''l''m''n''o''p''$, draw another curve, which will be the developement of the other side of the sofite. The developements of each of the parts of the sofite and of the two adjacent joint moulds give the three moulds for working one stone and the adjacent joints of the stone on each side of it. The angle which each of these joints makes with the sofite is found by making a bevel with one of its edges, circular for the intrados of the arc of the elevation, and the other to coincide with the joint line adjacent.

1984. *To find the moulds for executing a gateway in the quoin of a sloping wall.* Let ABCD (*fig.*655.) be the plan of the angle in which the arch is to be constructed, whereof AB is the span. Draw the centre line EL, to which draw the perpendicular FG. Prolong the line CA to F, and DB to G; then from the point L, as a centre, describe the sofite FHG and its extrados. Divide these arcs into equal parts for the arch stones, and from the divisions let fall perpendiculars, and also from the middle of the sofites to EC, ED. From the summits of the perpendiculars draw lines parallel to FG terminated by the lines of slope Set off the slope at the different heights *a*1, *a*2, *a*3, *a*4 respectively at right angles to the lines on the plan, on *d*1, *b*2, *d*3, *b*4, K5; also on the opposite side lay *a*2, *a*4 on *d*2, *b*4; then on one side draw the curve A*bb*K, and on the other, to abridge the work, join B*b*, *bb*, *b*K. Again, for the outer curve, or extrados, set off c1, c2, cG on *di*, *d*2, N3. On both sides draw the curve M*dd*O on the one side, and to abridge the labour, draw the straight lines O*d*, *dd*, *d*N.

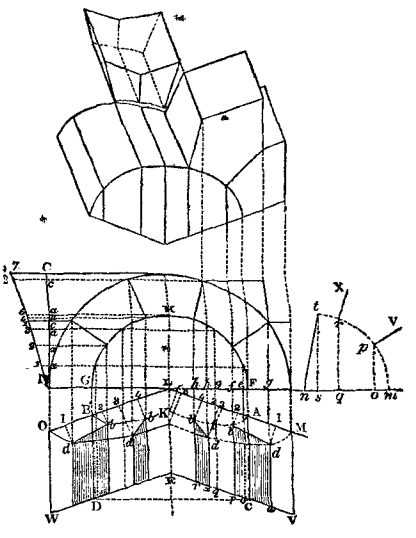

Fig. 655.

1985. *To find the moulds of the sofites.* Draw the line PQ (*fig.* 656.), on which lay the arc of the sofite FHG in the usual manner, making the points 1, 2, 3, which correspond to the points dividing such arc into equal parts; then on the lines of the sofite lay the distances FA, *fb*, *gb*, *hb*, LK, on PR, 1*k*, 2*l*, 3*m*, 4*m*, QS, and trace the front curve of the sofite R*klmn*S. Also repeat the same on the other side where there is only a straight line drawn from one sofite curve to another.

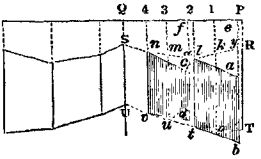

Fig. 656.

1986. *To find the back curve of the sofite.* Lay the distances *eo*, *fp*, *gq*, *kr*, LE on PT, 1*o*, 2*t*, 3*u*, 4*v*, QU, and trace the curve T*otuv*U.

1987. *To find the moulds of the beds or joints.* The sofite lines to which the beds belong are 2*t* and 4*v*. Draw the straight lines *eb*, *fd* parallel to QU, respectively distant from 2*t*, 4*v* by the breadth GI of the joint, and let the lines *be*, *fd* meet PQ in *e* and *f*; make *ea* equal to *gd*, and *ab* equal to *dw*, and join *al*, *bt*; make *fc* equal to *hd*, and *cd* equal to *dx*, and join *nc*, *vd*. To trace the stones by moulds, prepare the voussoirs with the head of the moulds of the straight arch FHG. The sofite should be hollowed in each voussoir by its particular mould: the rest is done as usual; but it must be observed, that if the sofite moulds are made with straight lines in front and near the sofite, it must not be hollowed till the last. The voussoirs may be worked by bevels, preparing the stones by the plans ACVM, BDWO, as for common imposts. Although the arch in each front be not absolutely necessary here, we shall give the method of constructing it. Let the line *mn* be drawn apart, on which lay the distances L5, L4, L2, LA on the lines *ns*, *nq*, *no*, *nm* square to *mm*. Draw the perpendiculars *op*, *qr*, *st*, on which lay the heights of the joints of the straight arch taken on the line of slope; that is, lay I2, on *op*, I4 on *qr*, I5 on *st*, and

draw the line *nt*, which is the slope. Then draw the curve *mprt*, and from the point *n* draw the joint lines *pv* and *r*X. The centre of this gate is represented (in the upper part of the diagram) with voussoirs, and the keystone placed behind to show the mitre of the centre. The sofite moulds serve for curving the ends of the stone where the intrados meets the surface of the two walls. It must, however, be observed, that, previous to the application of the sofite mould, the concave surface of the intrados must be formed by a mould with a convex edge, and then the sofite mould or moulds of developement must be bent into the hollow, so that the two parallel edges may coincide with the corresponding edges of the stone. The angles which the intrados makes with the joints are taken from the elevation of the face of the arch. This elevation is no more than a section of the arch perpendicular to the axis of the cylinder which forms the intrados.

1988. *To construct a semicircular-headed arch in a round tower or circular wall.* Let ABDC (*fig.* 657.) be the plan of the tower. Bisect the arc AB, and through the point of bisection draw EF parallel to the jamb line AC or BD. Through any point *a* in EF draw GH perpendicular to EF. Produce the lines CA and DB to meet GH in the points G, H, and GH will be bisected in *a*. From *a*, as a centre, and with the radius *a*G or *a*H, describe the semicircular arc GFH. Also describe the arc of the extrados and divide the arcs each into five equal parts, and let fall the perpendiculars of the joint lines, and those of the middles of the sofite curves to the inside circular line CED of the tower. Having extended the arcs of the intrados curve on the line IK, and having drawn the lines of the sofites and those in the middle of each sheet as before directed, lay off the distances between the right line GH and the circular outside line A*b*B, viz GA on IX and on KZ, *cd* on *ef*, V*g* on *hi*, S*k* on *lm*, M*n* on *op*, *ab* on *qr*; then trace the front curve on the sofite X*r*Z. To find the rear curve, lay GC on IY, *c*C on *e*S, &c., by which the rear curve will be obtained.

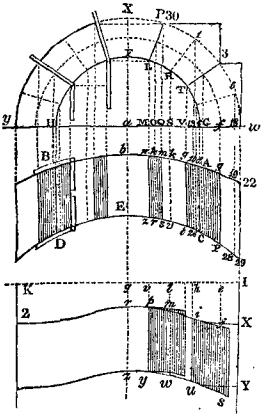

Fig. 657.

1989. We do not consider it necessary to pursue the construction of the moulds, the operations being very similar to those already given in the previous examples.

1990. *To find the moulds for an oblique semicircular arch in a circular tower.* The construction of this differs from the preceding only in the bevel or obliquity of the tower; hence it requires no particular description; only observing, that the bevel causes the mould to be longer on one side than on the other (see *fig.* 658.), as is evident from the plan; therefore the distances taken between the right line AB and the circular line of the tower CDE, being unequal, must be transposed each on its particular line of the mould and joint to which it corresponds in the sofite, that is, the distance AC must be laid on FG, BE on HI, and so of the rest. To work the stones, dress the beds, then apply the proper moulds and cut the head and tail circular as before. Trace the breadth of the sofite on the upper bed, then hollow the sofite, and cut the joints by the bevel.

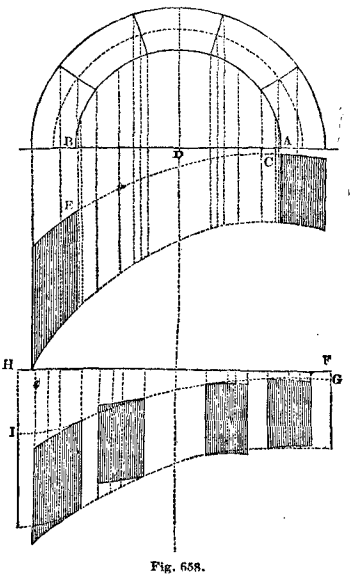

Fig. 658.

1991. *To construct an oblique arch in a round sloping tower intersecting a semicircular arch within it.* This is nearly the same as the two preceding cases. On one side draw the line of slope (*fig.* 659.) AB, and on the other the arc CD. Draw parallels from the divisions of the sofites and their middles, as in the figure, in order to cut the line of slope and arc. To work for the slope, set off all the retreats comprised between the perpendiculars AH and the line of slope AB on the perpendiculars of the sofite, square to the front line of the tower F 19 G, as follows: Transfer the retreat 9—10 on 19—20 by placing the compasses so that the line 19—20 would pass through the centre of the tower, and the point 20 fall on the centre of the gate O—75, and 7—8 on 17—18, and on 21—22 in the same manner (only terminated by the lines

from the sofite instead of the centre line of the arch), set also 5—6 on 15—16, and on 23—24, 3—4 on 13—14 and on 25—26, and lastly 1—2 on 11—12 and on 27—28, and through these points trace the sofite 28—20—11. The extrados is found in like manner, and the middles of the joints 47, 49, 53; which done, draw the plan of the joints 14—47—35, 18—19—37, 22—51—39, and 26—53—41.

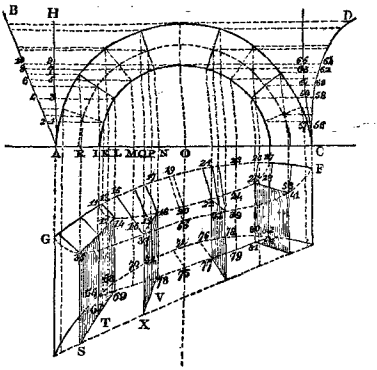

Fig. 659.

1992. *To find the curve of the plan which terminates the tails of the moulds.* Set the projections of the buttress of the semicircular arc at right angles to the inside line of the tower; viz. 64—65 on 74—75; 62—63 on 72—73 and on 76—77; 60—61 on 70—71, and on 78—79, 58—59 on 68—69. and on 80—81; 56—57 on 66—67 and on 82—83; then trace by hand the curve 83—75—66. The curves of the extrados and joints are found in the same manner.

1993. *To find the moulds of the sofite.* Draw the line of direction 94—84 (*fig.* 660.) as before, below which set off the distances I—11 or 84—85, K—12 on 86—87, L—14 on 88—89, M—16 on 90—91, N—18 on 92—93, O—20 on 94—95, and then trace the front of the sofite moulds 85—95—99. To find the rear, set I—66 on 84—33, K—67 on 86—36, L—69 on 88—100, M—71 on 90—98, N—73 on 92—97, O—75 on 94—96, and trace the rear curve of the mould 101—96—33.

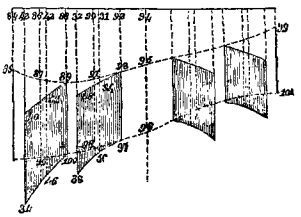

Fig. 660.

1994. *To find the moulds of the joints.* Transfer P—19 on 31—54, Q—37 on 32—48, I—47 on 42—52, R—35 on 43—40, and through these points trace the front joint or bed moulds 93—54—48, 89—92—40. To find the rear, make 31—50 equal to PV, 32—38 equal to QX, 42—46 equal to IT, and 43—34 equal to RS; which done, trace the curve lines 97—50—38 and 100—46—34. The two other joints are found by the same method. We do not consider it necessary further to multiply examples of the kind here given: the latter sort, especially, rarely occur in practice; and if they should, all that will be necessary to master the operations will be the application of a little thought and study.

1995. III. Of Dome Vaulting. In whatever direction a hemispherical dome is cut, the section A is always the same. B represents one half (see *fig.* 661.) of the same in the plane of projection. The construction is sometimes such that the plan is only a semicircle, as B, as in the termination of the choir of a church: in which case the French call it a *cul-de-four*; with us it is called a semi-dome.

1996. Through the extremities of the joints, and through the middle of each sofite of the section A, let fall on the line *ab*, perpendiculars, whereof all the distances *dc* from the centre *c* will be the radii of the arcs, which will serve for the developement of the sofites, of the joints, and for the construction of the arch stones. The method which follows, though it will not perhaps give the sofites and joints strictly accurate, will do so sufficiently for all practical purposes. Upon the developement C make SC equal to the arc MDGC, then set out to the right of the points of division the parts ST equal to *st* on the plan B; then raise through the points T upon the line SC perpendiculars equal

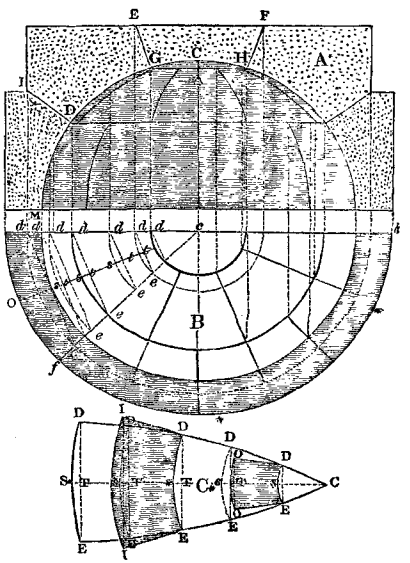

Fig. 661.

to the correspondents *e*, *t*, *d* of the plan B, and draw the curve ESD through the points so found.

1997. The sofites are terminated by four curves, whereas the joints have two right sides, as DI, EI, and DO, EO, and two curved sides, as II, DE, and OO, DE; the widths DI, DO of the joints are equal to DI, GE of the section; in one direction they are curved only one way, but as respects their sofites they are so in every way. The heights of the voussoirs are given by the section A, their bases on the plan B Thus G, I, in the voussoir next the keystone, being the most opposite points, the base of it on the plan will be comprised between the two arcs *dte*, which answer to the perpendiculars let fall from G and I. The base of the first voussoir, according to the first method, will be equal to the surface comprised between the arc *aof* and the arc *dse*, which answers to the perpendicular let fall from the point D.

1998. EF and GH are the diameters of the upper and lower bases of a truncated cone, whose lower surface is hollowed out spherically. After working the voussoirs, so as to make their bases such as we have just indicated, they must be worked to sofite moulds for giving them the hemispherical form of the section; after which the angles of the moulds are joined by arcs parallel to the arrisses of each stone, or by applying a general mould of the form of the section, that is, circular, of the radius of the dome.

1999. *For the pendentives formed in an hemispherical dome.* The piers D and E are supposed those of half the dome pierced by the pendentives. If we suppose the face or elevation B (*fig.* 662.) to make one quarter of a revolution about the point A, we obtain the elevations B and C. Through the points of division on the elevation C draw to the arc AD right lines perpendicular to CA. On the extremities of these lines upon CA, and from C, as centre, describe arcs in the plan F, by which the plan of the projection on F is obtained, whose intersections with the right lines drawn from B will give the joints and faces for the level beds. The lines HF, FE, ED are right lines. The spaces GAEF, FHIK are pieces of cylindrical vaulting, so that the only difficulty is in joining to each of their voussoirs their correspondent parts in ELMHFE.

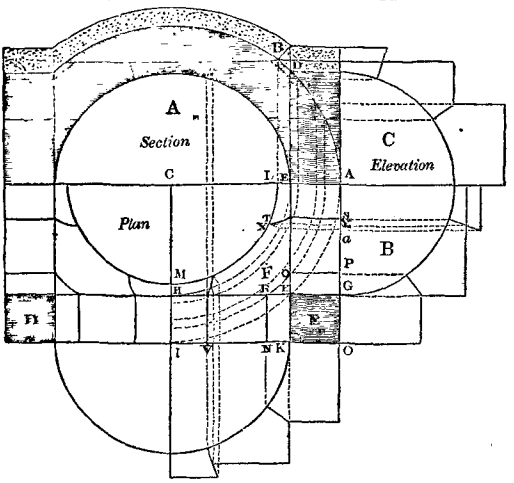

Fig. 662.

2000. The elevation B gives the height of the voussoirs; their bases, as seen in the preceding example, will be OPQRNO, GSTUVKFG. The length of the keystone will be XY, and *a*—A will be half its width.

2001. The part FQR is the plan of the springing stones of the pendentive in the elevation A. The remaining parts of the construction are sufficiently shown by the lines of the diagram, which will be understood by the student if he has previously made himself acquainted with the previous portions of this section.

2002. We should willingly have prolonged this part of our labours, if space had permitted us to do so without sacrificing other and important objects. If the subject be one in which more than the ordinary practice of the architect is called upon to put into execution, we refer him to Simonin, *Coupe des Pierres*, Paris, 1792, and Rondelet's *Art de Bâtir*, which we have used with much freedom, and in which many more interesting details will be found than we have thought it absolutely necessary here to introduce, though we believe we have left no important point in masonry untouched. We cannot close this section without paying our tribute of respect to the masons of this country, who are among the most intelligent of the operative builders employed in it. A very great portion of them are from the north of the island, and possess an astuteness and intelligence which far exceeds that of the other classes of artisans. We must not, however, altogether do this at the expense of those employed in carpentry, which will form the subject of our next section, among whom there will be found much skill and intelligence, when the architect takes the proper means of drawing it out; and we here advise him never to be ashamed of such means.

2002*a*. IV. Of Caissons in Cylindrical and Hemispherical Vaulting. — The method of setting out the *caissons* or sunken panels in cylindrical vaults and domes, is a process required almost in every building of importance, and imparts great beauty to the effect of the interior when properly introduced: it is, indeed, one of the elements in composing them, and must therefore be well understood before the student can succeed in developing his ideas.

2002*b*. In setting out the ribs of cylindrical vaulting, the vertical ones are supposed as falling on supports below the springing; but if such supports fall too wide apart, the caissons themselves will be too wide, and the space must be divided into a greater number; in which case, if practicable, an odd number is to be preferred, taking care that the caissons are not too much reduced in width. This, however, is only for the purpose of ascertaining roughly how many caissons may be used in the circuit of the vault; and it is to be remembered that they must be of an odd number, because a tier of caissons should always extend along the crown of the vault. *Fig.* 662*a*. is an example of a cylindrical vault wherein the

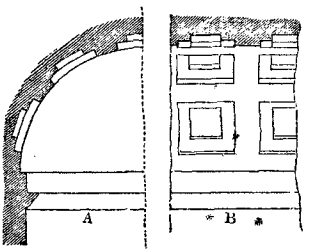

Fig. 662*a*.

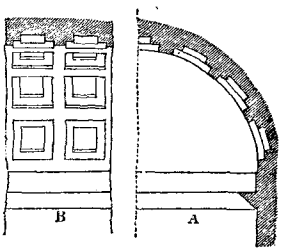

Fig. 662*b*.

number of caissons is five. A is one half of its transverse section, and B a small portion of the longitudinal section. The width of the ribs between the caissons is one third of them; hence, if the number of caissons, as in the example, be five, the arch must be divided into twenty-one parts, one of which parts will be the width of a rib, and three will be given to the width of a caisson. As we have just observed, a caisson is always placed in the centre; we shall therefore have the half-arch $= 1\frac{1}{2} + 1 + 3 + 1 + 3 + 1 = 10\frac{1}{2}$ and $10\frac{1}{2} \times 2 = 21$. The vertical lengths of the sides of the caissons thus found will regulate the horizontal lengths of their sides, inasmuch as they should be made square. If the caissons in the vault be seven in number, as in *fig.* 662*b*., the sofite or periphery must be then divided into twenty-nine parts; if their number be nine, into thirty-seven parts; and so on, increasing by eight each step in the progression. The caissons may be single or double sunk, or more, according to the richness required; their centres may be moreover decorated with *fleurons*, and their margins moulded with open enrichments. Where the apartment is very highly ornamented, the ribs themselves are sunk on their face, and decorated with frets, guilloches, and the like, as mentioned for ceilings in Book iii., c. i., s. xxiv. Durand, in his *Cours d'Architecture*, regulates the width of the caissons entirely by the interaxes of the columns of the building; but this practice is inconvenient, because the space may in reality be so great as to make the caissons extremely heavy, which is, in fact, the case in the examples he gives.

2002*c*. In the case of dome or hemispherical vaulting, the first point for consideration is the number of caissons in each horizontal tier of them; and the student must recollect that allowing, as before, one third of the width of a caisson as the width of a rib, the number of parts into which the horizontal periphery (whereof *e'e'* on the plan A is one quarter, and its projected representation at *ee* on the section B) is to be divided (*fig.* 662*c*.) must be multiples of 4, otherwise caissons will not fall centrally on the two axes of the plan. Thus,

A dome having 16 caissons in one horizontal tier must be divided into 64 parts.

—	20 ditto	-	-	-	-	-	80 ditto.
—	24 ditto	-	-	-	-	-	96 ditto.
—	28 ditto	-	-	-	-	-	112 ditto.
—	32 ditto	-	-	-	-	-	128 ditto.

and so on increasing by 16 for each term in the progression. In the figure, the number of caissons is sixteen. The semi-plan is divided into thirty-two parts, three whereof are given to each caisson, and one and a half to each half-caisson on the horizontal axis of the plan. From the divisions thus obtained lines are carried up to the section *ab*, *ab*, *cd*, *cd*. As the projected representations of the great circles of a sphere are ellipses, if from *b*, *b*, *d*, *d*, we construct a series of semi-ellipses whose transverse diameters are equal

to the semi-diameter of the sphere, and their conjugate axes determined from the points of intersection *b, b, d, d,* we shall have the vertical sides of the caissons. The next part of the process is to ascertain the ratio of diminution in the heights of the tiers of caissons as they rise towards the vertex, so that they may continue square in ascending. Upon a vertical line CC′, whose length is equal to the developed length of the line of dome *ef*, or in other words, whose length is equal to one quarter of the length of a great circle of the sphere, to the right and left of C set out at *g* and *g* the half width of the caisson obtained from the plan, and make *hg, hg* equal to one third of the caisson for the width of the ribs on each side. Draw lines to the vertex of the development from *hh* and *gg*. A diagonal *hi* being then drawn, the horizontal line *ik* will determine the lower edge of the next caisson upwards. Proceed in this way for the next from *l* and so on. The heights of the caissons thus obtained, being transferred to the section on the quadrant *ef*, will give the proportionate diminution thereon of the caissons as they rise. They are discontinued, and the dome is left plain, when they become so small as to lose their effect from below, and indeed they could not beyond a certain limit be executed.

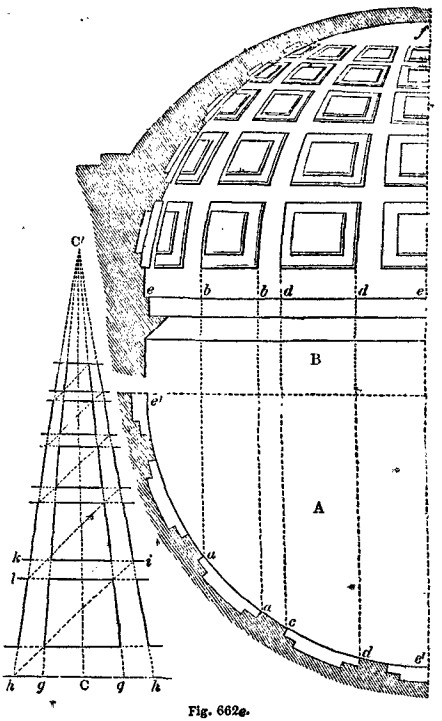

Fig. 662*e*.

2002*d*. V. OF GOTHIC VAULTING.—Professor Willis, in his valuable essay *On the Vaults of the Middle Ages*, printed in the Transactions of the Institute of British Architects, 1842, states that every rib should spring as a separate and independent arch, and that the elliptic curves produced by the method of obtaining the form by ordinates from those of the transverse ribs, are totally at variance with the characteristic forms of the Gothic style. De Lorme first taught this method, and others followed him, but it was never intended by them to be applied to Gothic rib-vaulting. This author shows (ch. viii.) that every rib is perfectly independent of the other in its curvature; each rib consists of a single arc of a circle whose centre is *upon the impost level*, and they cannot be therefore connected by projections. They all form pointed arches of different proportions, with the exception of the diagonal arch, which is very nearly a semicircle. "This," says Willis, "may have been the genuine French method, but in our English examples the centres are commonly placed without respect to the impost level, and the general forms of the vault are different from those which are produced in this manner." Dérand, writing later than De Lorme, says, "that in this style the ribs are always made arcs of circles, elliptical or other curves being inadmissible" (p. 177). Willis, later, however, allows certain ribs in a vault to be "semi four-centred arches," the others being arcs of circles. (See 1943*a*.)

2002*e*. "In the early stage of *rib-vaulting*," remarks Professor Willis, "the ribs consist of independent and separate voussoirs down to the level course from which they spring. The separate stones were roughly jointed at the back, instead of being each got out of a single stone, as in later structures. The back of these ribs is concentric with the soffite. The transverse rib of the north-east transept of Canterbury Cathedral consists of about one hundred richly-moulded stones, but the workmanship is exceedingly rude."

2002*f*. "The rough construction of the spandril, in the early instances, was followed at once by a more artificial structure, bespeaking a great advance in the art of masonry; and it remained with very slight change to the very latest period of rib-vaulting. This system is shown in *fig.* 662*d*. The junction of the solid mass L to N with the clearstory wall, is bounded by parallel vertical lines D, and this mass is always built of solid masonry bonded into the wall and forming part of it; the French name for this block of masonry is *tas de charge*. It is from the level of N that the real rib and panel work of the vault begins, for separate ribs are erected upon the surface of this solid, and

connected by vaults of a light material. The decorative construction, however, of the vault, exhibits the rib and panel from the abacus L, upwards. The point N is commonly at about half the vertical height of the arch, and is not necessarily guided by the impost of any clear-story rib adjoining. M is the general position where the mouldings of the several ribs run clear of one another at the divergence of the ribs. The solid part LM is built of horizontal courses of masonry, generally each of a single stone, and its level beds cut the curved mouldings obliquely in front."

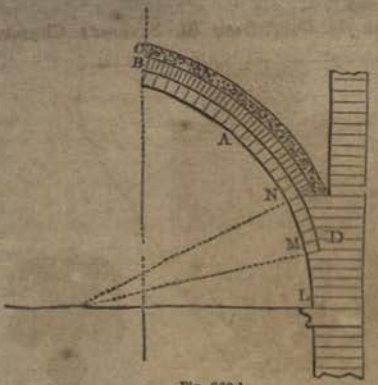

Fig. 662*d*.

2002*g*. Moller, *Memorials*, &c., translation 1836, p. 154, notices that, at Cologne, the lower part of the vaulting of the cathedral is formed by horizontal courses of stone projecting from the wall, consequently the actual span of the vaulting is proportionally diminished, while, on the other hand, the abutment is in the same degree strengthened. Still more deserving of attention is the manner in which the essential parts are so linked together as to be rendered incapable of thrusting or giving way, and therefore of necessity remaining in their original position. Price, in his work on *Salisbury Cathedral*, 1753, p. 25, quaintly remarks: "And here I beg leave to make a conjecture, that is, that all the springing stones of the vaultings were inserted into the walls at the time of their being erected, and so left till the whole church was roofed and covered in; and then being defended from rains, &c., they fixed their principal ribs and groins, and turned over the vaultings, as having the weight of the superstructure to act instead of a buttment."

2002*h*. "Above M," continues Professor Willis, "the ribs are each built separately of voussoirs, having their beds properly inclined to meet the axis of curvature of the rib, and these ribs are backed and united by solid masonry which connects them with the wall, and which, appearing between the rib, seems to be a portion of the light vaulting surface, really employed higher up. From the upper surface N, each rib A is still built as from M to N with voussoirs, but upon these ribs rests the light thin vault or panel-work."

2002*i*. "It is remarkable that the courses of the vaults are not laid level, but are in most cases made to incline downwards upon the diagonal rib. The reason for it is not easy to explain, but it is very common, especially in the earlier examples. These courses, in the transepts at Westminster Abbey, are of a light coloured stone, probably chalk, interrupted at regular intervals by a course of a darker stone; and the ridge, which has no rib, is also formed entirely of this darker stone, laid in a serrated manner. These dark courses are rather broader than the light ones, and there are four or five courses of the light between each of the dark. The surface of the panel between each rib is also made slightly concave or domical (probably to preserve the effect of being level, as seen from below it), and may therefore have been laid without any centreing, since each course would support itself. These peculiarities may all be found with some variations in other vaults of the same age."

2002*k*. "The architect of Leon cathedral," remarks Mr. Street, in his work on *Gothic Architecture in Spain*, p. 110, "filled in the whole of the vaults with a very light tufa, obtained from the mountains to the north of Leon; so at least I was assured by the superintendent of the works at the cathedral. Some of the material I saw was no doubt tufa; but some of it seemed to me to be an exceedingly light kind of concrete. The vaulting of Salisbury Cathedral is similarly constructed. I do not know whether at Beauvais the same expedient was adopted to lessen the weight." Both at Beauvais and Leon the construction in every part was too light.

2002*l*. Over the vaults was *commonly* laid a thick irregular course of rubblework, which again is also often covered with a kind of concrete. The vaults of the western compartments of Westminster, and of the south transept and tower of Hereford, are left bare on the upper surface: and these vaults, instead of being built with small brick-like stones, are composed of long thin slabs. The ribs themselves are, in some later examples, formed of a few long bar-shaped voussoirs instead of the small and numerous pieces of the earlier examples. Thus, in the transept at Westminster, L to N consists of 13 or 14 stones; but at the west end of the nave of 6 only.

2002*m*. Price notices (p. 24) that at Salisbury, "The groins and principal ribs are of Chilmark stone, but the shell, or vaulting between them, is of hewn stone and chalk mixed, on top of which is laid a coat of mortar and rubble of a consistence, probably ground in a kind of mill, and poured on hot, while the lime was bubbling; because by this, the whole is so cemented together, as to become all of one entire substance. This composition is

very remarkable, somewhat resembling the pumice-stone, being porous and light, by which it contributes prodigiously to the strength of the whole, and at the same time the least in weight of any contrivance that perhaps was ever used."

2002*n*. "The early moulded *ribs* are formed as *fig. 662f.* from St. Saviour's Church, Southwark, the vaulting or panel-work resting only on their backs; but the ribs of later date are rebated for the reception of this work, as shown in *fig. 662e.*"

Fig. 662*f*.

Fig. 662*e*.

2002*o*. As early as 1225–50, the square plans for vaults were superseded by oblong ones, which allowed the *cross-rib*, the *groin-rib*, and the *wall-rib* to arrive at nearly one level. In the new system the groin-ribs were portions of circles, and the cross-ribs were struck with the same radius; but these vaults were soon considered to be weak, and the cross-ribs were heightened while the groin-ribs were either stilted or (subsequently) sharper pointed.

2002*p*. As soon as mediæval builders admitted the principle that the strength of arch-stones, like that of beams, is more dependent on the depth than on the width, they reduced the width as much as they could in order not to require a large abacus to the capital. The next step was to resolve all thrusts upon that support into a force acting directly upon it; and consequently to endeavour to make the various pressures, which the pillar has to bear, combine in a point in a stone that should be fully as large in plan as the abacus, and perhaps rest upon others of the same character.

2002*q*. The operation of deciding the form and place of this stone is very simple after the size of the arch-stones has been determined. Supposing that the work is, as in a cloister, bounded by a wall, and without wall-ribs, there will only be a cross-rib and two groin-ribs to be heeded. A line AB (*fig. 662g.*) showing the face of the wall is to be cut in O by another line CD representing the centre of the cross-rib; and the plan of the arch-stones for that rib is to be projected by the aid of these lines. It gives at the wall a centre O, and in its length OE *on the central line* a radius with which a semicircle may be described (as shown by the dotted line); a couple of parallel lines, FG and HK, will now show the thickness of the cross-rib. To proceed with a groin rib, a line from O must be laid down at the correct angle made by the groin with the wall; and the plan of the groin-rib must be so projected that, with this line for an inside line, the front of the arch-stone shall touch the semicircle. A couple of parallel lines MN and PQ will now show the thickness of the groin-rib; and the plan of the abacus of the pillar may be designed, even so as to allow of wall-ribs if they should be intended.

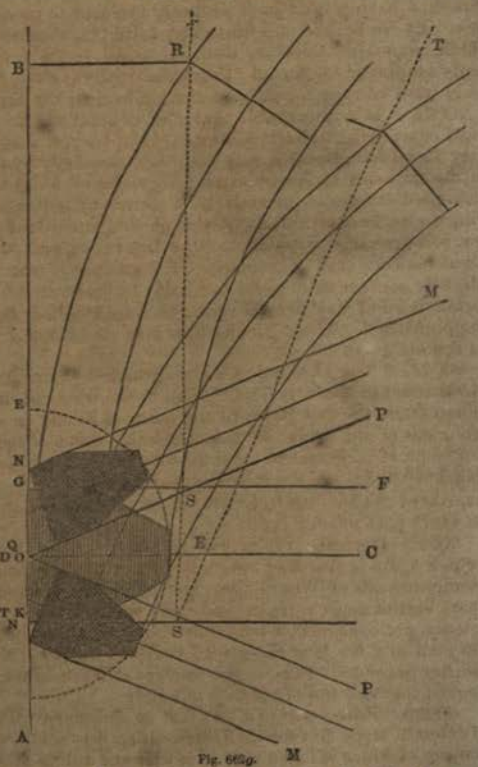

Fig. 662*g*.

2002*r*. The use of the semicircle is not an indispensable, but is a naturally convenient step, because the equal quantities so taken by it from all the spans of the ribs leaves undisturbed in general result all calculations founded upon lines drawn from mathematical points that are taken as centres in a plan made to a small scale; but the plans of the groin-ribs may be placed anywhere upon their respective centre-lines

so long as the intersection or junction of the neighbouring lines of the widths of the ribs is secured at some point. This intersection is not an absolute necessity, but it is the means of reducing the size of the abacus; and the point of junction S is that beyond which (working from the wall) the two ribs will be distinct. Taking this point S as fixing a line for the springing, the elevations of the two arches are to be drawn on the intersecting lines; then lines SR and ST drawn perpendicular to the springings, will cut the extrados of each arch at points which decide the level of the top bed of the horizontal work. The mass of work between this bed and the capital will be divided into a convenient number of courses, and the plans of the beds thus fixed are easily drawn from the elevations of the arches; when it will be seen that, if the groin-ribs are less in depth than the cross-ribs, the former will give a good starting-place for the material which is to form the spandrils of the vaults. In a similar manner, the intersections of any number of ribs may be found, and the tertiary and secondary ribs may be successively suppressed in favour of the primary principal ones. Viollet le Duc, *Dictionnaire*, s.v. Construction, p. 96. Prof. Willis gives the following illustration (*fig. 662h.*) showing the method of setting out mouldings for vaulting, belonging to the perpendicular period; it is taken from one of the spandrils of a complex vault which formerly covered the extreme north-western compartment of the nave of Canterbury Cathedral, the lower storey of the so-called Lanfranc's tower. The number of ribs being seven required two stones in each of its upper courses at least; *fig. 662h.* being only a portion of the spandril, contains but four of them. It also shows that the stone had been scored, then rejected, and another set of lines drawn, and actually employed. AB, AC, are the rejected centres, and D a portion of the first outline. EF, EG, EH, and EI are the true lines drawn, each parallel to its own rib. The average thickness of the courses is about 10 inches.

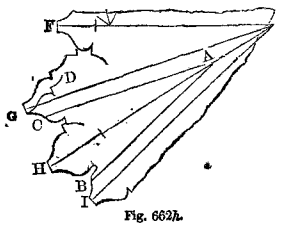

Fig. 662h.

2002*s.* The *key-stone* or *boss-stone* was adopted by the mediæval architects as a necessary appendage to groin-ribs, because the solidity of the vaulting depends greatly upon the pressure exerted by the key, which must consequently be heavier than any of the arch-stones; it will necessarily be an extremely large stone, allowing a great part of its mass to be cut away by the sculptor in order to diminish its apparent heaviness. This stone should generally be nearly circular in plan; for if the ribs diverge enough to leave any large space between them, a fracture is almost certain. In cases of such divergence, it is best to design the sculpture so that a mass may occupy the space. This remark, of course, does not apply where there are only two groin-ribs meeting at right angles; but it governs the amount to which the groin-rib should be allowed to be worked in the key-stone. No part of the boss ought to be sunk within a horizontal line connecting the intrados of one rib with that of another; and it is generally desirable that, whether or not the ribs be back-jointed for the filling of the groining, as *fig. 662f.*, the key-stone should have a projection or tail sufficient to stand above the back of the filling. "Every boss-stone," says Professor Willis, "had its upper surface made horizontal, on which were drawn the lines from the axis of the boss in the direction of the respective ribs." The principles here indicated are illustrated in *fig. 662i.*

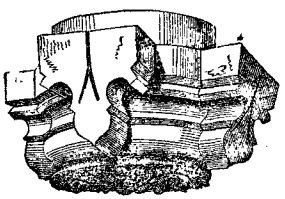

Fig. 662i.

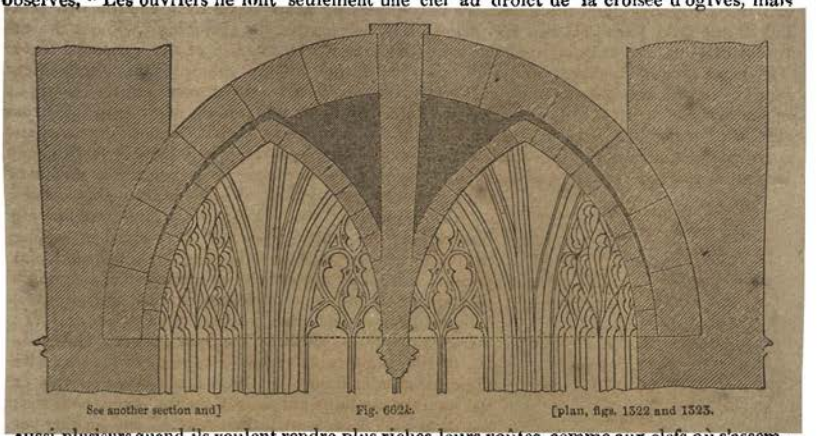
2002*t.* In the construction of groined vaulting it has been considered best to fix the key-stone on the centreing, before laying the arch-stones, for the sake of the guidance which it affords in the work; the inconveniences of working a boss in its place, and of setting it if already worked, were obviated in the 13th century by leaving its breast smooth, so that a wooden boss, carved at leisure, might be fastened to it with hooks. In the 15th century such a boss was not unfrequently of stone instead of wood.

2002*u.* A striking feature of the Flamboyant style is the frequent use of *pendents* in the vaulted roofs of the period. These, however, are not confined to the Continent, for the Tudor period in this country exhibits many splendid instances of their employment, none, perhaps, more gorgeous, or more interesting as regards its construction, than the Chapel of Henry the Seventh. Some of the various examples that exist have been scientifically investigated by Professor Willis, in his paper *On the Construction of the Vaults of the Middle Ages*, already quoted; and we therefore now proceed merely to indicate the principles upon which the fairy-like system of not only suspending vast bosses from the ceiling was conducted, but that by which these bosses or pendents became in their turn the springers for supporting other vaults, as in the beautiful little Lady Chapel at Caudebec in Normandy, and many other examples. A plan is given in the section on Principles of Proportion.

2002*v.* This chapel is hexagonal on plan, about 23 feet in span, or from side to side.

Fig. 662*k*. shows the mode by which, from the key-stone of an arch approaching a semicircular form, and suspended or elongated beyond its ordinary depth, support is given for the springing of the vaults of the different bays. On this practice Philibert De Lorme observes, "Les ouvriers ne font seulement une clef au droict de la croisée d'ogives, mais



See another section and] Fig. 662*k*. [plan, figs. 1522 and 1523.

aussi plusieurs quand ils veulent rendre plus riches leurs voûtes, comme aux clefs où s'assemblent les tiercerons et liernes, et lieux où ils ont mis quelquefois des rempants, qui vont d'une branche à l'autre, et tombent sur les clefs suspendues, les unes étant circulaires, les autres en façon de soufflet, avec des guymberges, mouchettes, claire-voyes, feuillages, crestes de choux et plusieurs bestions et animaux: qui étoient trouvés fort beaux du temps qu'on faisoit telles sortes de voûtes, pour lors appelées des ouvriers (ainsi que nous avons dict) voûtes à la mode françoise."

2002*w*. We have shown above the mode of suspending the pendent in a polygonal building. The *fig.* 662*l*, by a little consideration, will explain the mode of suspending pendents not centrically situate, as in the case of the ceiling of Henry the Seventh's Chapel, whose date runs coincident with the Flamboyant period. The figure is a transverse section and plan of the vaulting of the building, in which one of the main arches, on which the whole construction depends, springs just below A, and reaches its summit at B. The voussoirs or arch-stones whereof it consists are marked in their order. The dotted interval from *a* to *b* is not to be considered as an interruption of the formation of the arch by the pendent, but may be supposed an imaginary line passing through it, or rather through the arch-stone or voussoir C, whose general form is marked by the bounding letters *c d e f b a*; so that, in fact, the pendent is nothing more, as in the case of the Lady Chapel at Caudebec, than a voussoir, a large part whereof hangs down below the face of the vaulting. The voussoirs are out of blocks about 3 feet 6 inches deep; but a considerable portion of the solid below the soffite of the arch is cut away to form the lobes of the cinquefoils. The arch D serves, by its connection with the walls, to stiffen and give weight to the arch where it would be most required, that is, towards the springing. The pendent or voussoir E, on the same block with C, being thus established in its place, serves at, or towards its foot, as a springer for the ribs of a fanwork tracery shown on the plan, whose ribs are, in fact, ribs of a dome, and in construction do not differ from it. Their section is shadowed somewhat lighter than the pendent voussoir. The fanwork round each affords the means of introducing another pendent at its meeting at F in the plan. (This pendent is shown at F in the two sections given in PRINCIPLES OF PROPORTION.) The *fan* vault is very properly distinguished by Prof. Willis from what he calls the *stellar* vault, which is formed of ribs that may be, and indeed frequently are, of different curvature, and the rays of the star of different lengths; whereas the fan vault consists of ribs of the same curvature and height, and the summit of the fan is bounded (see the *fig.*) by a horizontal circular rib, instead of the ends of lozenges forming the points of the star. "The effect of the fan is that of a solid of revolution, upon whose surface panels are sunk: the effect of the star is that of a group of branching ribs." It is manifest that the constructive details of these two sorts of vaulting are vastly different. In the one, the dependence is upon ribs which support, by rebates on them, the filling-in panels; while in the other the principle is similar to that of dome-vaulting. This will be immediately perceived by reference to the plan G, in which the courses are marked, as also in the part of the section marked H. The plan I shows the tracery of the soffite of the vault. The author above quoted observes, "The construction of these fan vaults is in all examples so nearly the same, that they seem to have proceeded from the same workshop; and it is remarkable that, at least as far as I know, there are no

Continental examples of them; whereas, of the previous vaults, there are quite as many on the Continent as in England. In France, indeed, the lierne" (ribbed) "vaults are not

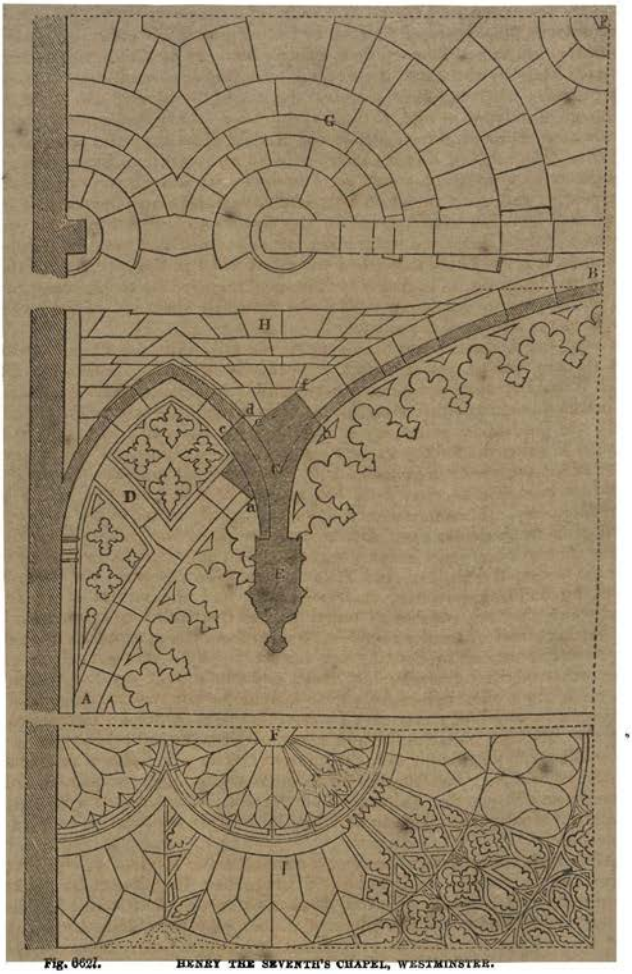


Fig. 662f. HENRY THE SEVENTH'S CHAPEL, WESTMINSTER.

very numerous; they are confined to small chapels, and their patterns are in general simple. But in Germany and in the Netherlands there is an abundance of them, distinguished, certainly, from ours by local peculiarities, but nevertheless of similar mechanical construction, and requiring the same geometrical methods."

2002*x*. The introduction of fan vaulting seems to have occurred in the beginning of the 15th century. The first instance wherein the span was considerable is the Dean's Chapel attached to the north-west transept of Canterbury Cathedral. In St. George's Chapel at Windsor, the aisle and central compartment only have fan vaults, the principal vault not being fanwork. The chief works of this kind, of known date (about 1500), are Henry the Seventh's Chapel at Westminster, King's College Chapel at Cambridge, the central tower of Canterbury, and Bath Abbey church. (See PRINCIPLES OF PROPORTION.) In the church of St. Etienne du Mont at Paris, we find a remarkable example of the style of the renaissance contending with the expiring flamboyant style. In short, the whole of the interior is a mass of interesting incongruities. The church is cruciform, and at the intersection of the cross is a pendent key-stone, most elaborately wrought, and more than 13 feet deep. It is obvious, in respect of these pendents, that there is no mechanical difference between their pendency and their being insistent, as lanterns are, on domes.

SECT. IV.

CARPENTRY.

2003. Carpentry is the science of framing or letting into each other an assemblage of pieces of timber, as are those of a roof, floor, centre, &c. It is distinguished from joinery in being effected solely by the use of the *axe*, the *adze*, the *saw*, and the *chisel*, which are the carpenter's tools; whereas joinery requires the use of the *plane*. See 2102, *et seq.*

2004. Though necessarily of high antiquity, the very scanty information which Pliny and Vitruvius have left us on the subject would merely show that the science was known by the ancients. The roofs of Egypt present us with no more than flat coverings of massy stone; a pediment roof, therefore, would seem to have been among the first efforts of constructive carpentry; and upon the pitch which this, then and since, has received in different countries, we shall hereafter have to speak. The Greeks appear to have used carpentry in the construction of their floors and some other purposes; but in a country abounding with stone and marble, it is not likely that wood was much used in the interiors of their buildings, unless where lightness, as in doors, for instance, required its employment. With the Romans it was much more commonly used; and from all that can be gathered, we may consider them as the fathers of the science.

2005. Among the moderns it has been very successfully cultivated; and, with very few exceptions, we may almost assert that the works of Palladio, Serlio, De Lorme, Sir Christopher Wren, Perronet, and a few others, exhibit specimens which have scarcely been surpassed in later times, notwithstanding the scientific form it has assumed in the present age.

2006. To the mechanical principles of carpentry we have, in Chap. I, Sect X. of this book, directed the attention of the student; and to the section now under our pen we should have added the words *Descriptive* and *Practical* to *Carpentry*, but that much of what could have been said on that head has already been anticipated in the section on Descriptive Geometry. Hence, in what follows, that which comes under such predicament will be only given in particular cases, for the purpose of saving time and trouble to the reader in the application of its principles to them. We must, here, also remind the reader, that under the section BEAMS, &c., and TIMBER, have been described the different sorts of timber used for building purposes, their strengths, and the strains to which they are subject and which they are capable of resisting; and that therefore this section is confined simply to putting pieces of timber together, so as to form the assemblage of timbers under which we have commenced by defining the science. To do that properly requires great skill and much thought. Considerable waste, and consequent expense to the architect's employer, result from that ignorance which assigns to the scantlings of timber larger dimensions than are absolutely necessary for the office of each piece; insufficient scantlings will bring the architect into trouble and responsibility; and the improper connection of the pieces will be equally ruinous to his reputation. The principles of practical carpentry are, nevertheless, simple; and though to form new combinations and hazard bold and untried experiments in practice will require all the skill and science of a talented artist, the ordinary routine of carpentering is to be learnt by a little application and a due exercise of common sense.

2007. After these observations, we must introduce the student to the first operation which in practice may arise. It is not every where that timber can be obtained in sufficient lengths to stretch across the void he has to cover; and it will in such cases be necessary for him to know how one piece of timber may be so joined to another, for the purpose of lengthening it, that the two pieces, when joined, may be as nearly as possible equal in strength to one whole piece of timber of the same dimensions and length. This operation is of great service to the builder, and is technically called *scarfing*. To perform it, the joints are indented, and bolts are passed through the pieces within the length of the indents, such bolts being confined above and below by means of nuts and screws. In *fig.* 663. four ways are exhibited of accomplishing the object in question. A and B are the methods usually employed for joining together plates, lintels, and ties, in which bolts are rarely necessary; but if such a method is used for scarfing beams, bolts must be employed. The stronger forms, which only should be used for beams, shown in C and D, are not only in that respect such as should, on that account, be used for beams, but are executed without loss of length in the pieces of timber. The length of the joints of the scarfing may be increased at pleasure; the diagrams are merely given to show the mode of doing what was required. With fir, however, when bolts are used, about four times

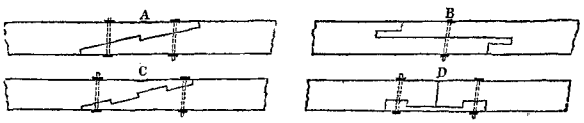

Fig. 663.

the depth of the timber is a usual length for a scarf. Scarfing requires great accuracy in execution; for if the indents do not bear equally, the greater part of the strength will be lost: hence it is improper to use very complicated forms for the indents.

2008. Pieces of timber are framed into and joined to one another, by the aid of *mortices* and *tenons*, and by iron straps and bolts; and on the proper placing of these depends the soundness of the work. If a piece of framing is to stand perpendicularly, as in the case of partitions, without pressure from either side, the mortice and tenon should be in the centre of the wood. But in the case of framing floors, in which the pressure is on the upper surface, and entirely on one side, the mortices and tenons ought to be nearest the side on which the pressure is, by which the timber will not be so much weakened; and hence it is the constant practice to cut the mortices and tenons as in *figs.* 664, 665. By the method shown in the last-named figure, the tenon obtains more strength from an additional bearing below, which is further increased by the inclined butment above, called a *tusk*.

Fig. 664.

Fig. 665.

2009. The method of framing wall plates together at an angle, for the reception of the hip rafter on the *dragon beam*, and the angle ties for retaining the wall plates in their places, is shown in *fig.* 666., wherein AB is the mortice cut for the tenon of the hip rafter

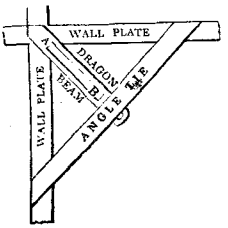

Fig. 666.

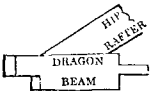

Fig. 667.

Fig. 668.

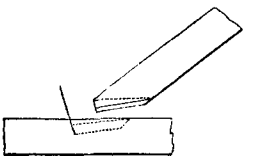

Fig. 669.

shown in *fig.* 667. *Fig.* 668. is one of the wall plates, showing the halving to receive the other plate, and the cutting necessary for dovetailing the angular tie. *Fig.* 669. shows the method of cutting the mortices and tenons of principal and hip rafters; another method being given in *fig.* 670., and to be preferred where a greater resistance to thrust is sought, because by it a double *butting* is obtained on the tie beam. Inasmuch, however, as in this last case the beam is cut across the grain to receive the rafter, the part left standing to receive the heel of the rafter may be easily split away; to obviate which, the socket may be cut, as at A, parallel to the grain of the wood. *cd* is the iron strap for securing the rafter's foot to the tie beam, and keeping it in its place. A plan of the upper part of the tie beam is given at B, showing the socket and mortice of the section A in the last figure. C exhibits the mode in which a principal rafter is strapped to a tie-beam, with the *joggling*.

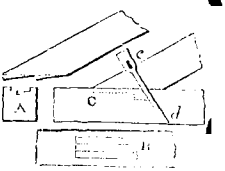

Fig. 670.

2010. The most approved method of forming butments (*fig.* 671.) for the *struts* or *braces*, *aa*, which are joggled into the king-post, is to make their ends, which act against the joggle, perpendicular to the sides of the brace; they will thus be kept firmly on their butments, and have no tendency to slide. C is a section of the king-post and tie beam, showing the mode of wedging and tightening the strap, with a single wedge, in order to draw the tie beam close to the king-post. D is a section of the same parts to a larger scale, and with the introduction of a double wedge, which is easier to drive than a single one, because there is less action upon the cross grain of the wood.

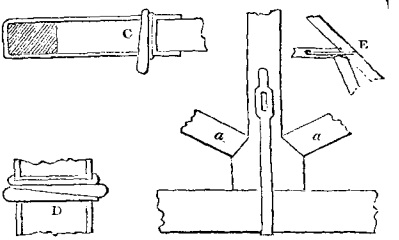

Fig. 671.

2011. Straps in carpentry should be sparingly used. Professor Robison has very properly observed, that "a skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art." The most important uses of them are, that of suspending the tie beam to the king-post, and of securing the feet of the principal rafters to the tie beams in roofs.

2012. Bolts are sometimes used for the last-named office, with *washers* and heads and screw nuts, in which case the washers, nuts, and heads should be well painted, though

even then they are liable to rust. Wherever the iron work used for securing a system of framing is exposed to the humidity of the atmosphere, it should be rendered durable by frequent painting. Price (*British Carpenter*, 1759) observes thus: "There is one particular that had liked to have escaped my notice, concerning the placing of iron straps on any truss, thereby meaning to help its strength, which is by turning the end square (as shown at E, *fig.* 671.). This method embraces the timber in such a manner, to make it like a dovetail, *which cannot draw from its place*; another observation is, to bolt on your straps with square bolts, for this reason: if you use a round bolt, it must follow the auger, and cannot be helped; by this helping the auger-hole, that is, taking off the corners of the wood, you may draw a strap exceeding close, and at the same time it embraces the grain of the wood in a much firmer manner than a round pin can possibly do." The example given by Price, however, for turning square the strap, is injurious to the rafter, which must be partially cut to admit of it.

FLOORS.

2013. The assemblage of timbers in a building, used for supporting the flooring boards and ceiling of a room, is, in carpentry, called *naked flooring*, whereof there are three different sorts, viz. *single flooring*, *double flooring*, and *double-framed flooring*. But before entering on the particulars of either of the sorts, we will make some general observations on the construction of floors, which require the architect's attention. First, the wall plates, that is, the timbers which lie on the walls to receive the ends of the girders or joists, should be sufficiently strong and of sufficient length to throw the weight upon the piers. Secondly, if it can be avoided, girders should not lie with their ends over openings, as doors or windows; but when they do, the strength of the wall plates must be increased. To avoid the occurrence in question, it was formerly very much the practice in this country, and indeed is still partially so, to lay girders obliquely across rooms, so as to avoid openings and chimneys, the latter whereof must indeed be always attended to. Thirdly. Wall plates and templets must be proportionately larger as their length and the weight of the floor increases. Their scantlings will, in this respect, vary to 4½ by 3 inches, up to 7½ by 5 inches. Fourthly. The timbers should always be kept rather higher, say half to three quarters of an inch higher, in the middle than at the sides of a room, when first framed, so that the natural shrinking and the settlement which occurs in all buildings, may not ultimately appear after the building is finished. Lastly, when the ends of joists or girders are supported by external walls whose height is great, the middles of such timbers ought not at first to rest upon any partition wall that does not rise higher than the floor, but a space should, says Vitruvius (lib. 7. c. 1.), be rather left between them, though, when all has settled, they may be brought to a bearing upon it. Neglect of this precaution will induce unequal settlements, and, besides causing the floor to be thrown out of a level, will most probably fracture the corners of the rooms below.

2014. Single Flooring is constructed with only one series of joists (as shown in *fig.* 672.). In this way of framing a floor, if a girder is used, it should be laid as nearly as possible over the centre of the apartment. A *single* floor containing the same quantity of timber as a double floor is much stronger; but the ceiling of the former is liable to crack, and cannot be got to so good a surface when finished. Hence, where the bearings are long, it is much better to use double flooring.

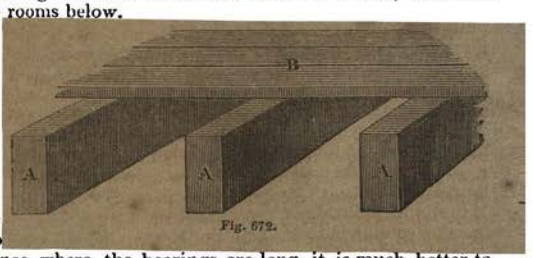

Fig. 672.

2015. The scantlings of fir joists for single flooring are exhibited in the subjoined table, and are founded on our own practice. The weight of a square varies from 11 to 18 cwt.

Length in Feet.	Width in Inches.	Depth in Inches.
6	2	6
8	2½	7
10	2½	7½
12	2½	8
14	2½	9
18	2½	12
20	3	12

These scantlings may be varied if wanted, according to the laws laid down in the section Beams, Pillars, &c.; 1622. *et seq.*

2016. In *fig.* 672. AAA are the joists, and B the floor boards. The laths for the ceiling are nailed to the under side of the joists AAA.

2017. In most floors, on account of the intervention of flues, chimney openings, and occasionally other causes, it will so happen that the ends of the joists cannot have a bearing on the wall. In such cases a piece of timber called a *trimmer* is framed into two of the nearest joists (then called *trimming joists*) that have a bearing on the wall. Into the trimmer, which is parallel to the wall, the ends of the joists thus intercepted from tailing into the wall are mortised. The operation is called *trimming*. The scantlings of trimmers and trimming joists may be the same as those hereafter given for binding joists; or if to the width of the common joists an eighth of an inch be added for each joist supported by the trimmer, the depth being the same, the scantling will generally be sufficient.

2018. When the bearing of a single joist floor exceeds 8 feet, a row of strutting pieces should be introduced between the joists, by which they will be prevented from horizontal twisting, and the floor will be stiffened. If the bearing be more than 12 feet, two rows of stiffening pieces or struts should be introduced, and so on for each increase of 4 feet in bearing. They should be put in, in continued rows, and be well fitted. Beyond a bearing of 15 feet it is not advisable to use single flooring, neither ought it in any case to be used where it is required to prevent the passage of sound.

2019. A *double floor* consists in its thickness of three tiers of timbers, which are called *binding joists* (these perform the office of girders), *bridging joists*, and *ceiling joists*. From an inspection of *fig.* 673. the construction will be easily understood. AA are the binding joists, which are the principal support of the floor on the upper side, whereon BB, the bridging joists are notched; which is the best method, though sometimes they are framed between with *chased mortices*. The binders, of course, run from wall to wall; and as for carrying the floor, the bridging joists, as their name imports, are *bridged* on to them; so the lower tier of timbers, called the *ceiling joists*, are either notched to them, or are what is called *pulley mortised* into them; that is, a chase D is cut in the binder long enough to allow tenons of the ceiling joists C being obliquely introduced into them, and driven up to their places. The scantlings of timbers used in this method are the same as those for double-framed flooring, of which, indeed, it is but a species.

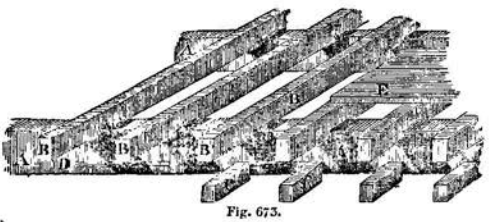

Fig. 673.

2020. The *double-framed floor* differs only from the last-named by the binding joists, instead of going from wall to wall, being framed into large pieces of timber called *girders* (as shown in *fig.* 674.), wherein A is the girder, B a binding joist, C a bridging joist, D a ceiling joist, E the pulley mortice for the ceiling joist D, and F is the floor. The great advantages of this sort of flooring are, that it prevents the passage of sound between the stories, and enables the architect to make a solid ceiling.

Fig. 674.

2021. As in a double-framed floor the girders are the chief supports, it is exceedingly important that they should be sound and free from shakes. The distances between one girder and another, or the wall, should not exceed 10 feet, and their scantlings as in the following table: —

Girders of the length of	10	feet should be	9 inches deep, 7 inches wide.
	12	—	10 8
	14	—	11 9
	16	—	12 10
	18	—	12 11
	20	—	13 11
	22	—	14 12
	24	—	15 12
	26	—	16 12
	28	—	16 13
	30	—	16 14

2021*a*. Girders or beams whose bearing exceeds 24 feet are difficult to be procured of sufficient depth, in which case an expedient is put in requisition to strengthen a less depth. The principles it involves are explained under the head of roofs, namely, those of *trussing* them (2031, *et seq.*), an operation that converts the beam within its own thickness into a piece of framework, for the purpose of preventing the bending, or, as it is technically called, its *sagging*, which produces an injurious horizontal thrust on the walls. This operation is represented in *fig.* 675, in two different ways. No. III represents the plan.

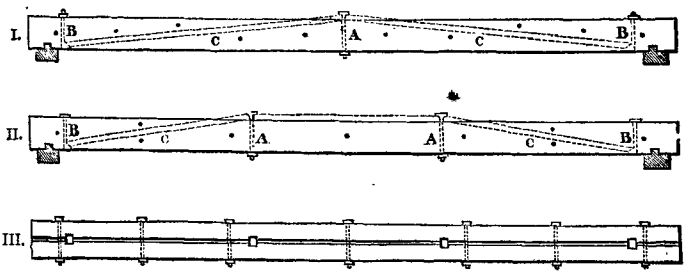

Fig. 675.

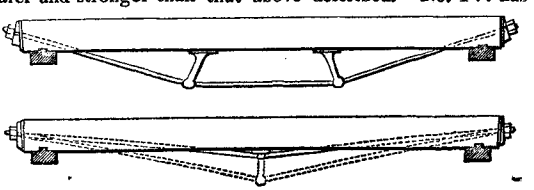
The beam is cut into two halves in the direction of its depth and length, between and into which the truss is inserted, as shown. It is better that the *truss posts* A, and *abutment pieces* B, should be of wrought iron; the *struts* C may be of oak, or some stiffer wood than the beam itself. In I. and II., the whole, or nearly the whole of the timber, is in a state of tension.

2021*b*. This operation is further developed by trussing the beam *below* itself, an arrangement considered to be safer and stronger than that above described. No. IV. has a wrought iron tension rod, with a stay in the centre, which takes the whole of the tension, whilst the timber is thrown entirely into compression. No. V. is the same with two stays. By these systems a beam, rafter, purlin, &c., which will barely support its own weight safely, may be made to carry a load of many tons without sensible deflection. The tension rod is useful in proportion to its distance from the beam (evidently within certain limits). If it be immediately under, or concealed *within* the under edge, it becomes nearly useless, especially in a cast iron beam with a wrought iron rod, where the beam is much less extensible than the rod. In such a case, the beam would break and fall before the rod has been brought into action. The respective size or sectional area of the rod and beam is regulated by the respective strength of the materials, as it is useless to apply a rod capable of sustaining double the tensile force that the beam can resist of crushing force, and *vice versâ*; it is merely adding weight (Warr, *Dynamics*, page 259.). The flitch girder is described in par. 1629*u*.



2021*c*. The resistance of beams of soft wood may be considerably increased by strengthening the centre of gravity. Du Hamel, *Force des Bois*, took twenty-four sticks, cut from young willows, of equal strength. Each stick was 3 feet (French) long, and 1½ inch square. Six of these broke in the middle with an average weight of 566·48 lbs. In two other pieces he made a cut *across it* ⅓ inch deep in the centre, and filled it out with a piece of oak; these broke with an average weight of 594·73 lbs. Two more were cut ½ inch deep, and treated in the same manner; they broke with 585 lbs. Five were cut ¾ inch deep, and broke with 572·78 lbs. All the trials showed that the piece of harder wood increased the strength of the beam.

2021*d*. Laves's girder is a simple and effective contrivance for strengthening a beam. The piece of timber having been cut nearly from end to end (*fig.* 675*a*.), is bound at each termination with an iron strap. Blocks are driven in the cut so as to separate the severed pieces to several inches distance in the middle of the length, thereby throwing

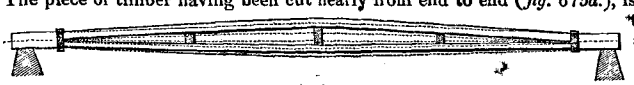


Fig. 675*a*.

the material farther above and below the neutral axis. A solid beam, 40 feet long, 9¼ inches deep, and 7¼ inches wide, deflected 5¼ inches with a load of 1,700 lbs. When a similar beam had been cut to 3·6 inches of each end, making the upper part 5 inches deep and the lower part 4¼ inches, and separated by blocks until the parts were as wide asunder as half the depth of the beam, the beam suffered a less deflection by 1¾ inch. A greater strength was obtained by separating the parts to the whole depth of the beam, when it deflected 3 inches less than the solid beam; and when separated to 1½ times the depth, it deflected 4 inches less than the solid beam. The greatest strength is obtained by giving a section to the upper and lower parts proportional to the power of the material to resist tension and compression (*Civil Engineer* for 1840, page 161, being the paper read at the Institute of British Architects).

2022. We now return to the subject of binding joists, which ought not to be more than 6 feet apart. The depths, if necessary, for accommodating them to the thickness of the floor, may be varied from the following table by the rules given under section Beams, &c.

Binding joists of the length of 6 feet should be 6 inches deep, 4 inches wide.

8	—	7	4½
10	—	8	5
12	—	9	5½
14	—	10	6
16	—	11	6½
18	—	12	7
20	—	13	7½

The scantlings of bridging joists are similar to those already given for single flooring. These, as well as ceiling joists, whose scantlings are subjoined, should not be more than 12 inches apart, and they require to be scarcely thicker than is necessary to bear the nails of the laths fixed to them, for which 2 inches is quite sufficient.

Ceiling joists of the length of 4 feet should be 2½ inches deep, 1½ inch wide.

6	—	3½	1½
8	—	4	2
10	—	5	2
12	—	5½	2½

The weight of a square of framed flooring with counter flooring varies from 22 to 36 cwt.

2023. Though, perhaps, more curious than useful, we should not perform our duty to the student, were we to omit a method of constructing floors with short timbers, where long ones are not to be procured. Suppose it be required to floor the room ABCD (*fig.* 676.)

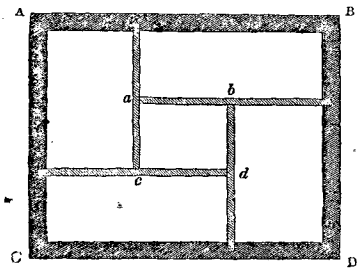

Fig. 676.

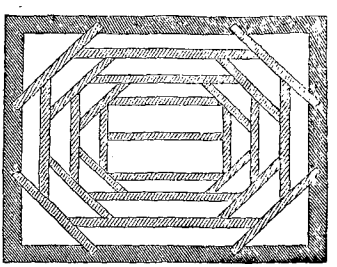

Fig. 677.

Let four joists, as in the figure, be mortised and tenoned at *abcd*, as there shown. Now it is evident that these joists will mutually support each other, for each is supported at one end by the wall, and at the other by the middle of the next joist. *Fig.* 677. shows another mode of accomplishing the same object; and many other forms would immediately suggest themselves to the experienced architect. The expedient is of ancient origin, inasmuch as our old master (so we delight to call him, notwithstanding the new lights that modern critics have found to guide them), Serlio, has described the expedient without any difference. In the fourth volume of Rondelet (*Art de Bâtir*), an author to whom we are under infinite obligations, is described a floor executed at Amsterdam for a room 60 feet square, of exceedingly singular construction, inasmuch as it is without joists at all. Each side of the room is provided with very strong wall plates, whose angles are secured with iron straps, and are rebated to receive the flooring, which consists of three thicknesses of 1½ inch boards. Of these thicknesses, the first is laid diagonally across the opening, its ends resting on the rebates of the wall plates, and rising about 2½ inches towards the centre of the room. The next (second) thickness is laid diagonally at right angles to the first thickness, and the two are well nailed together. In the third thickness,

the boards are laid down parallel to one of the sides of the room, and form the upper side of the floor, being, however, well nailed to those below. The whole of them are *grooved* and *tongued* together, forming a solid floor 4½ inches thick. In this example is an instance well worthy the study of the architect, as respects a scientific connection of parts, and the great advantage of a well-disposed bond. The floor in question is, in fact, a thin plate, well supported round the edges, the strengths of the plates being directly as the squares of their thicknesses, equally strong to bear a weight in the middle, whatever their bearing; though if the load be uniformly distributed, the strength will be inversely as the area of the space.

2023*a*. The flooring of the Middle Ages, as used for upper rooms, were constructed with large square timbers resting on wood plates, which formed the cornice to the rooms; sometimes they had stone cornices under them. Occasionally the under sides of the joists were covered with boarding, and this was divided into panels by small ribs, with bosses at the intersections, carved with foliage, or with shields of arms, or other ornaments. An example of the 15th century exists at Wingham, in Kent; Parker, *Dom. Arch.* iii. 127. These were usually coloured in distemper. The ceiling of the nave and of the eastern part of St. Alban's Abbey church is a remarkable example of a fine flat *ceiling* of early date, as is also that in the tower of the church at St. Cross, in Hampshire, and that of the library, 15th century (and formerly in the chapel) of Merton College, Oxford. In England, in the 13th century, the ceilings (which were of wood) were frequently painted the same as on the wainscot, in green and gold, and were sometimes also decorated with historical subjects and with gilded bosses.

2023*b*. The joists that came upon a beam were placed upon it, and, being cut, were pinned into corresponding blocks. If the beam took two sets of joists, the blocks might be made long enough to connect the ends of the two sets. But by the 14th century the system of girders, binders, and joists was perfected; boarding one inch and a half thick, rebated on both edges, was laid with the wider face downward, and connected by rebated battens, fixed upon stop-moulded joists, and these were dovetailed for half their depth into moulded binders, that were dovetailed three-fifths of their depth into moulded girders, the backs of all being flush for the boarding, which received the mortar and tile floor.

2023*c*. Whether in oak or fir, this latter system was apparently never enriched with painting, but moulded and carved; indeed the inevitable towel decoration makes its appearance in panels formed by moulded strutting. These panels are let into rebates on the back of the struts and joists and binders, so as to leave a space between the panels and the flush floor, receiving the plaster or the tiles upon plastering. Another effective practice was to rebate the backs of the joists sufficiently deep to allow the apparent *ceiling* to consist of short pieces of board that were decorated on the two edges, laid close together, forming a pattern of circles, diamonds, foils, &c., cut in open work, with a ground formed by laying a plank over the whole length between the joists; over this came the finished one, or three coated floor. In the 15th and 16th centuries, pendentives hanging by keys to timber ceiling-joists, between binders, formed an entirely new arrangement of decoration, which rivalled in its complexity of drops and coffers the most elaborate works of Saracenic ceilings. In the time of Henry VIII., the ceilings were commonly of plaster, with a great variety of patterns stamped in them. The ceiling of the chapel of the Savoy Palace in the Strand is a rich example of panelling only.

2023*d*. Some of the timber houses built in Troyes at the commencement of the 16th century afford good specimens of the manner in which the construction of the floors was rendered ornamental. The studs of the framing carry the usual head-piece, which is moulded; and on this are notched down the ceiling joists, which have their ends cut as cantilevers: upon these rests a board, or plank, having its edge moulded, which is kept in place by the chantlates at the feet of the rafters. At other times the sill is separated from the joists; because they rest upon stanchions, upon which are planted brackets carrying the ends of the joists: between the ends, which are grooved, there is a piece of carved woodwork, so that the ends of the joists, in conjunction with a moulded plate resting upon them and receiving the tie beams or ceiling joists, form a sort of corbel-table. (*Fig.* 701*l*.)

2023*e*. Another method of forming a floor, with its ceiling, into decorated construction, is due to the 15th century. This consisted in cutting balks of timber diagonally and laying them with the angles downward close together. The ends were notched into the girders or binders, leaving flush backs. If not sightly enough, triangular fillets were put in between them; and the sharp angle might even be taken from off the arris or under edge of the balks. Floors were also composed of brick segment arches (the bricks being set herring-bone) between balks of timber laid with one corner upwards, so as to form a skew-back for the arches.

2023*f*. For these few remarks we are indebted to Viollet le Duc's admirable *Dictionnaire*. As the systems therein shown will scarcely be adopted in England in general practice, the student will do well to refer to the work should he require any illustrations. A very

suggestive late example, richly moulded and carved, as it existed before 1843 at Fontainebleau, when it appears to have been reused and somewhat altered, is given in that work among many others.

2023*g*. *Timber groined ceilings* are to be met with in the choir and lady chapel at St. Albans'; in Warmington Church, Northamptonshire, of the Early English period; in the cloisters at Lincoln and Gloucester; in the towers at Exeter; in the lantern at Peterborough; the lantern at Ely, and the choir at Winchester, cathedrals; in the choir at Selby Abbey Church, Yorkshire; in the nave of Boston Church, Lincolnshire, where it unfortunately occupies 22 feet of height; the chapel of St. Mary's College, Winchester, and the entire roofing of York Minster. The vaults spring from stone-work carried up as high as required to free the ribs from the wall; there is no special mark of division at the point where the stonework ceased and the woodwork commenced. The boarding was let into a groove in the sides of the ribs, or laid on a rebate. The eastern part of the chancel of the 13th century church at Uffington, in Berkshire, is evidently groined or prepared for groining in this way, for whilst the walls and buttresses were insufficient to resist the thrust of a vault even filled in with chalk, the stone springers exist. "There seems to be no good reason," continues Mr. Street, from whose lecture on *Woodwork* we are quoting, "why this kind of ceiling should be condemned, as it has been by some writers, as though it were unreal, or in any way a sham. It is nothing of the kind, and no attempt was made to make the wood look like stone. The boarding was frequently feather-edged, and grooved and tongued, and thus obviously of wood. (*Fig.* 780*f*.) It may be introduced in buildings not calculated to resist the thrust of a stone vault; and it may be carried far up into the roof and above the top of the walls, which in stone vaults is always, within a little, the limits of internal height attainable."

PARTITIONS.

2024. The framework of timber used for dividing the internal parts of a house into rooms is called a *partition* or *quartered partition*. It is commonly lathed and plastered; when the spaces between the timbers or quarters are bricked up, it is called a *bricknogged partition*. The weight of a square of common partition is rarely less than from 13 to 18 cwt.; hence it becomes necessary to take care that partitions should not be set upon the floor, without taking due precaution to relieve it of the weight, either by struts, braces, or the formation of a truss in it. When a partition occurs in an upper story, under a strongly trussed roof, it may be often advantageously suspended from the roof, and its weight thus taken off from the floor below. If it have a solid bearing throughout its length, it requires nothing but struts between the quarters; but these are not absolutely required. The scantlings of the timbers of a quarter partition should vary according to the extent of bearing. Where that does not exceed 20 feet, 4 by 3 inches will be sufficient; and where it is as much as 40 feet, the quarters should not be under 6 by 4 inches, that is, supposing it to bear only its own weight. When it has to bear more, the scantling must, of course, be increased accordingly.

2025. *Fig.* 678. represents a design for a trussed partition, with a doorway in the centre

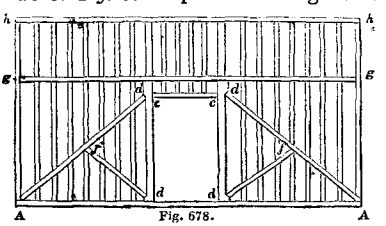

Fig. 678.

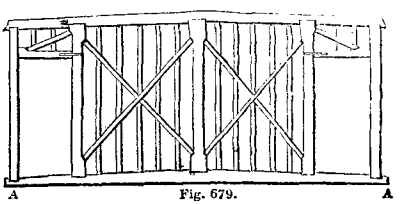

Fig. 679.

of it: 'in which *hh* is the head, and AA the sill; *dc*, *dc* the doorposts; *gg* the *intertie*, A*d*, A*d* the braces; *fd*, *fd* struts. *Fig.* 679. shows a method of trussing a partition in which the doors are at the sides. It is obvious that additional strength may also be gained, when wanted, by introducing a truss between the intertie and head of a partition. The angle of inclination of braces should be about 40° with the horizon.

CARRIAGE OF STAIRS.

2026. The framed timbers which support the steps of a staircase are called the *carriage*. They generally consist of two pieces inclined to the pitch of the stairs, called the *rough strings*. When geometrical stairs consist of two alternate flights with a half-pace between them, the carriage of the half-pace is constructed with a beam parallel to the risers of the

steps, whose joists are framed into the beam for the support of the flooring. This beam is called the *apron piece*, and that which sustains the rough strings at the upper end is called the *pitching piece*. The joists of the half-pace are sometimes turned into the pitching piece, and sometimes bridge over it; but the steps of both flights are always supported by string pieces, as before. The upper ends of the string pieces at the landing rest upon an horizontal piece of timber, called, as above, an apron piece. The scantlings of the strings, of course, vary with the length of the inclined part. The depth given to joists of similar length will be more than sufficient.

ROOFS.

2027. The first obvious consideration in constructing a roof is the slope to be given to it, which depends on the climate against which it is to serve as a protection, and on the materials to be employed in covering it. In hot countries, rain more rarely falls than in temperate ones; but when it comes, it descends very abundantly, which, added to the temperature of the air, makes it unnecessary to give a great slope to the roof, from which the water immediately runs, and the air dries it almost at the instant of the rain's cessation. In cold countries the rain is more searching, the air is more impregnated with moisture, and snow often lies for a long time on a roof; circumstances which require a greater proportional slope to be given to it. Again, roofs covered with lead, zinc, or copper, do not require so great a slope as those covered with tiles or slates. (See ROOFING, in Glossary.)

2028. Though among architects there does not appear to have been any fixed principle by which the slope should be determined, we find that in different climates suitable slopes have been adopted for similar materials. Thus in the southern parts of Europe we find the roofs very flat; whilst as we proceed into its northern parts the roof acquires a very considerable elevation. We shall here transfer to our pages the notice of this subject in the *Encyclopedie Methodique*, which we consider extremely important and interesting, inasmuch as it shows that necessity was the parent of beauty in the inclination of the roofs of the ancients; and in the times of the middle ages it had some influence even in the production and developement of the lancet arch.

2029. The researches and observations made respecting the roofs of a great many ancient and modern buildings, situate in different countries, satisfy us that the slopes of roofs which have lasted best are always proportioned to the temperature of the climate. Before entering into the consideration of any law for determining the slope of a roof, it will be proper to comprehend the meaning of the word climate as here introduced, which we shall use in the same way as it is understood by geographers. According to them, the climates of the globe are comprised under belts or bands, of unequal size, parallel to the equator. Of them there are twenty-four between the equator and the polar circle, each of half an hour; that is, the length of the longest day of a place situated at the beginning of the climate is always shorter by half an hour than that of the place situated at the extremity of the same climate, or at the beginning of the succeeding one, proceeding from the equator towards the polar circle. This difference in the length of the day, caused by the greater or less obliquity of the tropic with the horizon, is one reason of the different degrees of temperature of countries corresponding to the different climates. We are not, however, to assume that the temperature will be exactly the same for all places under the same climate, since there are many circumstances which tend to make a place more or less damp, in which cases the slope of the roof should rather have a relation to a more northern spot. In the roofs of the Continent covered with the hollow tile, as in the south of France for instance, less slope is required than with the Roman tiles (see the word TILE in Glossary), which are in sections alternately flat and circular; and these, again, require less slope than the common plain tile or slate. From the observations that have been made, we find that the slope of roofs covered with hollow tile, thus, of the south of France, should be after the rate of three degrees for every climate, beginning from the equator and proceeding northward, and that when the Roman tile is used, an addition of three degrees should be made to such inclination; an addition of six degrees, if covered with slates; and of eight degrees, if covered with plain tiles. According to this law, the table which will be presently subjoined has been constructed, and a comparison of it with ancient buildings gives a remarkable corroboration of its value. Thus, at Athens, situated about the middle of the sixth climate, the slope of a pediment would be about $16\frac{1}{2}^\circ$; and that of the Parthenon is actually about 16°; that of the temple of Erectheus, $15\frac{1}{2}^\circ$; of Theseus, 15°. In Rome, which is about one third of the way up the seventh climate, the Roman tile requires an inclination of 22°. The actual slope of the pediment of Septimius Severus is 23°; those of the temples of Concord and Mars Ultor, $23\frac{1}{2}^\circ$; of Fortuna Virilis and the Pantheon, 24°; and, of more modern date, the slope of the roof of St. Paolo fuori le murà was 23°.

2030. We shall now give the reader the table above mentioned. The argument at the head of each column will render its further explanation unnecessary.

City.	Country.	Climate.	Length of longest Day.		Covered with							
					Hollow Tiles.		Roman Tiles.		Slates.		Plain Tiles.

"There is no article," says Ware in his *Body of Architecture*, "in the whole compass of the architect's employment that is more important or more worthy of a distinct consideration than the roof. The great caution is," continues our author "that the roof be neither too massy nor too slight. Both extremes are to be avoided, for in architecture every extreme is to be shunned, but of the two the overweight of roof is more to be regarded than too much slightness. This part is intended not only to cover the building, but

to press upon the walls, and by that bearing to unite and hold all together. This it will not be massy enough to perform if too little timber be employed, so that the extreme is to be shunned. But in practice the great and common error is on the other side; and he will do the most acceptable service to his profession, who shall show how to retrench and execute the same roof with a smaller quantity of timber; he will by this take off an unnecessary load from the walls, and a large and useless expense to the owner."

2031. We shall now proceed to a popular view of the strains exerted by the timbers of roofs, referring the reader back to the section on BEAMS, PILLARS, &c., for a more extended and scientific view of them. Suppose (*fig.* 680.), in the simplest form of roof, the rafters (shown by dotted lines) AB, CB to pitch upon the walls A*a*, C*c*. Let the rafters be supposed to be connected together at B as by a hinge, as also similarly connected with the walls at A and C. Now if the effective weight of the walls be not sufficient to resist the thrusts of the rafters, as respects the height, thickness, and situation of the centre of gravity of such walls, taken as solid masses and moveable on the points X and Y, it is manifest the rafters by their own gravity will descend, and the walls will spread and be thrown out of an upright, as in *ab* and *cd*, and the rafters will take the places shown in the figure. It has already been shown (par. 1633) that the horizontal thrust of a pair of rafters thus meeting each other, is proportional to the length of a line drawn perpendicularly from the rafter's foot until it intersects a vertical line drawn from its apex. As the roof therefore becomes flatter, the length of the perpendicular increases. Hence, if AB and BC be the rafters, and their weights be represented by their lengths, the weight or power of thrust exerted by the rafter AB in the direction of its length will be represented by BO, and the horizontal thrust by AO; AO being perpendicular to AB. To secure, then, the walls in their perpendicularity, which the thrust of the rafters tends to derange, a system of framing becomes necessary. Thus, in *fig.* 681., a beam AC, which from the office it performs of tying or confining the feet of the rafters is called a *tie beam*, is introduced across the opening, and into this beam the rafters are framed. If the tie is introduced above the level of the walls, it is called a *collar beam*, as *ac*. It is manifest that these beams exert their power in the same way that a string would, that is, that the principal strain which they have to perform is in the direction of their length, and hence, that for such especial purpose, if they be prevented from *sagging* or bending, a small size or scantling will be sufficient, for we have already seen that the cohesive power of timber is very great in the direction of its length. To take care that the tie beam thus introduced should be strained only in the direction for which it is used, we are now led to another expedient. The beam by its own gravity, especially in a large opening, would have a tendency to sag or bend in the middle, and the more so if its scantling be simply proportioned to its office of a tie. To prevent this a fresh tie is introduced called a *king-post* DB (*fig.* 682.), by which the beam is tied or slung up to the apex of the principal rafters; and this combination of a pair of rafters, a tie beam and a king-post, is called a *truss*, and is the most important of the assemblages which the carpenter produces. When the rafters are of such length that they would be liable of themselves to sag down, supports *aa* are introduced at the points where such failures would occur, and these supports are called *struts*, because their office is to strut up the rafter, which they should do as nearly as the case will admit in a direction perpendicular to the slope of the rafters.

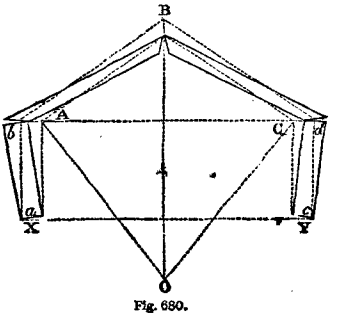

Fig. 680.

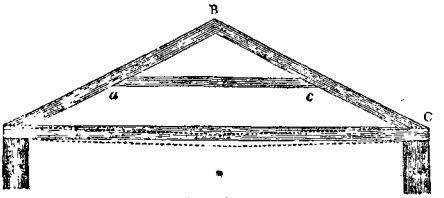

Fig. 681.

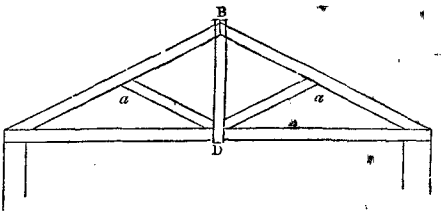

Fig. 682.

2032. It is clear that out of this last case a fresh system of trusses may arise as in *fig.* 683., for from those points procured by the struts against the rafters, new rods may

be slung for increasing the stiffness of the tie beam *ad infinitum* in theory, but not in practice, because the compressibility of the fibres of timber is considerable in lines perpendicular to their direction, and the contraction and expansion of metal places a limit to its use. This compression of timber deserves great attention on the part of the architect. We may lay down as a rule in respect to it that the more the weights or pressures act in the direction of the fibres, the less will be the compression.

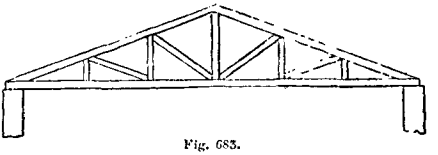

Fig. 683.

2033. To exemplify this, *fig.* 684. shows in No. 1. the principal rafters of a roof butting in an ordinary roof, against the shoulders AB, CD of the kingpost, whose fibres, being vertical, are compressed by the pressure against it, on each side of the rafters, whereby they approach each other, causing the whole figure of the roof to suffer a change. For by the action of compression and its consequence the kingpost must descend, and with it, consequently, the tie beam which is slung up to it. To remedy the inconvenience in roofs constructed of fir, the kingpost is often made of oak, which is less compressible, a practice which should be observed in all roofs of consequence. But cast iron kingposts are the best substitute where the expense can be justified. In No. 2. the end is accomplished much more economically by *housing* the rafters in the head of the kingpost at the angle in which the rafters meet, by which the fibres of the rafters butt against each other, bringing the compression nearer to that which takes place in a post according as the rafters are less inclined to each other, and the beam is then literally suspended from the vertical planes of the rafters at their junction.

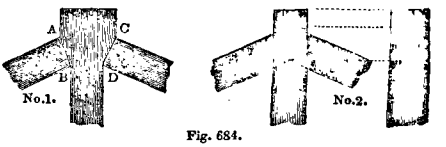

Fig. 684.

2034. When a roof (*fig.* 685.) is trussed by two upright suspending posts, which become necessary in increased spans, such posts, AB, CD, are called *queen-posts*, and the piece between them, BD, is called a *collar*, which acts as a *straining piece* to prevent the heads of the queen-posts moving out of their places towards each other. It will on mere inspection be seen that this roof has three points of support, B, E, and D; for by means of the struts AE, EC, a new suspending point is gained from E for sustaining the tie beam between the points A and C. It is also to be observed that the collar or straining piece BD performs in this assemblage an office exactly the reverse of that which it does in *fig.* 681.

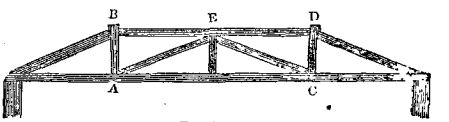

Fig. 685.

2035. The *Mansard* roof, so called from its inventor's name, and with us called a *Curb roof*, frequently used for the purpose of keeping down the height of a building, and at the same time of obtaining sleeping or other rooms in it, is shown in *figs.* 686 and 687. It may be considered as primarily consisting of four pieces of timber connected by hinges at the points ABCDE. If these be inverted, they will arrange themselves by their gravity in such a manner that when returned to their first position they remain in a state of equilibrium, which, however, in practice is but a tottering one, and requires additional expedients to prevent the whole assemblage thrusting out the walls; and, moreover, to prevent the upper rafters from acting by their thrust to displace the lower ones. To obtain these ends the first object is to introduce the tie AE; and, secondly, the tie BD. It is to be understood that means are to be used, when needed from their length, to prevent these beams from bending, similar to those already directed in the cases of simple trusses. *Fig.* 686 is an example selected from Krafft, (*Art. de la Charpente*, fol. 1805), having an arched ceiling to give additional height to

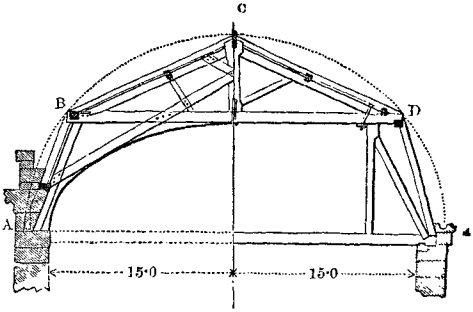

Fig. 686. Fig. 687.

some large or public room. This form of roof has been frequently adopted in the palaces of France and Germany. *Fig.* 687 is a king-post Mansard roof, affording a wide space over the tie beam available as an apartment. *Fig.* 698 is an example of the principles adopted for a much wider spanned roof.

2035*a*. We have thus far endeavoured to explain in the simplest way the conduct to be pursued for obtaining stability in the construction of a roof; but before we proceed to the scantlings of the timbers to be employed, the reader must be informed that the trusses to roofing, with whose nature he has now become acquainted, are placed only at certain intervals (which should not exceed 10 feet) apart, and are thus made to bear the *common rafters* and the weight of the covering, as well as to perform the office of suspending the tie beam by which the walls are kept together. Hence the rafters so framed in a truss are called principal rafters; and by the means of a *purline* A (*fig.* 688.), which lies horizontally throughout the roof's length on the principal rafters, they are made to bear all the superincumbent load. The purlines are in various ways made fast to the principal rafters, and upon it the common rafters are usually notched down. Their bearings are thus lessened, and less scantlings suffice for them. They are received at their feet on a piece of timber (B in the figure), which runs longitudinally along the sides of the building. This piece of timber is called a *pole plate*, from being the uppermost plate in a building; at their summits they abut against a *ridge piece* D. When a roof slopes each way, the space enclosed between the intersection of the slopes is called a hip (*fig.* 689.); and the longest rafters in it, which are those at the angles, are called *hip rafters*, and the shorter ones are named *jack rafters*, as A, A, A, &c.

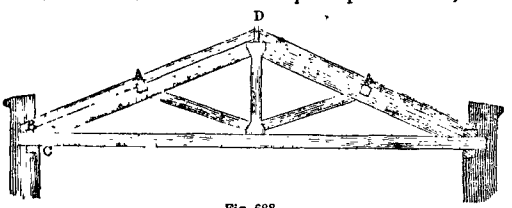

Fig. 688.

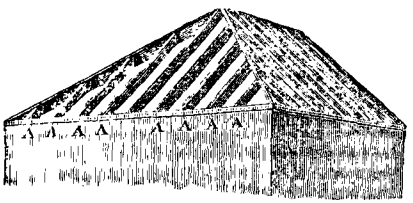

Fig. 689.

2036. We have, at the beginning of this section (2007.), observed, that the use made of bolts must be always in a direction as nearly as possible counter to the strain which the pieces exert; the method, therefore, of introducing them will, on due consideration, be sufficiently obvious.

Before proceeding to lay before the reader some few examples of roofs suitable to different spans, as well as of some of magnitude which have been executed, it may be as well to complete this portion of our labour, by giving some information on the scantlings of timber for roofing, in which a medium, founded on our own practice, is introduced between ignorant overloading, and fanciful theory.

2037. For roofs whose spans are between 20 and 30 feet, no more than a truss with a king-post and struts will be necessary, in which case the scantlings hereunder given will be sufficient.

For a span of 20 feet, the tie beam to be 9 in. by 4 in.; the king-post, 4 in. by 4 in., principal rafter, 4 in. by 4 in.; struts, 4 in. by 3 in.

For a span of 25 feet, the tie beam to be 10 in. by 5 in.; the king-posts, 5 in. by 5 in.; principal rafter, 5 in. by 4 in.; struts, 5 in. by 3 in.

For a span of 30 feet, the tie beam to be 11 in. by 6 in.; the king-post, 6 in. by 6 in., principal rafter, 6 in. by 4 in.; struts, 6 in. by 3 in.

2038. For roofs whose spans are between 30 and 45 feet, a truss with two queen-posts and struts will be required, and a straining piece between the queen-posts. Thus —

For a span of 35 feet, the tie beams to be 11 in. by 4 in.; queen-posts 4 in. by 4 in.; principals, 5 in. by 4 in.; straining piece, 7 in. by 4 in.; struts, 4 in. by 2 in.

For a span of 40 feet, the tie beams to be 12 in. by 5 in.; queen-posts, 5 in. by 5 in.; principals, 5 in. by 5 in.; straining piece, 7 in. by 5 in.; struts, 5 in. by 2½ in.

For a span of 45 feet, the tie beams to be 13 in. by 6 in.; queen-posts, 6 in. by 6 in.; principals, 6 in. by 5 in.; straining piece, 7 in. by 6 in.; struts, 5 in. by 3 in.

2039. For roofs whose spans are between 45 and 60 feet, two queen-posts are required, and a straining piece between them; struts from the larger to the smaller queen-posts, and struts again from the latter.

For a span of 50 feet, tie beams, 13 in. by 8 in.; queen-posts, 8 in. by 8 in.; small queens, 8 in. by 4 in.; principals, 8 in. by 6 in.; straining piece, 9 in. by 6 in.; struts, 5 in. by 3 in.

For a span of 55 feet, tie beams, 14 in. by 9 in.; queen-posts, 9 in. by 8 in.; small queens, 9 in. by 4 in.; principals, 8 in. by 7 in.; straining-piece, 10 in. by 6 in.; struts, $5\frac{1}{2}$ in. by 3 in.

For a span of 60 feet, tie beams, 15 in. by 10 in.; queen-posts, 10 in. by 8 in.; small queens, 10 in. by 4 in.; principals, 8 in. by 8 in.; straining piece, 11 in. by 6 in.; struts, 6 in. by 3 in.

2040. The scantlings of purlines are regulated principally by their bearing; and though we have subjoined scantlings for bearings of 12 feet, such should be avoided by not allowing the distances between the trusses to exceed 10 feet. Thus—

For a bearing of 6 feet,	the scantling of the purline should be	6 by 4.
8 feet,	—	7 by 5.
10 feet,	—	8 by 6.
12 feet,	—	9 by 7.

For common rafters the scantlings are as follow; 12 feet should be the maximum of the bearing.

For a bearing of 8 feet	the scantling of the rafter should be	4 by $2\frac{1}{2}$.
10 feet,	—	5 by $2\frac{1}{2}$.
12 feet,	—	6 by $2\frac{1}{2}$.

2040*a*. To determine the size of a rafter for a roof to support the covering of slate, the distance between the supports being 6 feet, and the weight of a superficial foot, including the stress of the wind, being 56 lbs.; the deflection not to exceed $\frac{1}{40}$th of an inch for each foot in length; the formula becomes:—56 lbs. × 6 feet = 336 lbs., and $\frac{336 \text{ lbs.} \times 40 \times 6^3}{E = 3072 \times 6} = 157{\cdot}5$ of which take $\frac{5}{8}$ths for uniform load = 98·44. If the breadth be made $2\frac{1}{2}$ inches, then $\frac{98{\cdot}44}{2{\cdot}5} = 39{\cdot}3$, and the cube root of 39·3 is 3·4 inches, the depth required. These are the rules given by Barlow (page 179.), who, in the several editions of his work on *Strength of Materials*, put the "reduced tabular value" for Riga fir, E = 96, and 32 times E became 3072; and for English oak E = 105. In the edition of 1851, this has been altered to E = 192, and 16 times E = 3072 also, for fir; or for oak E = 210. The reason of this change has been explained in Beams and Pillars, par 1630*m*.

2040*b*. Another element in the calculation for timbers above-named, is the weights of the different materials used in covering buildings; these are roughly stated to be as follows:—

A square of	pantiling	about	$7\frac{1}{2}$ cwts.,	also put at	650 lbs.	$\frac{2}{5}$
"	plain tiling	"	$14\frac{1}{2}$ "		1780 "	$\frac{2}{7}$
"	stone slating	"	— "		2380 "	$\frac{2}{7}$
"	slating, a mean	"	$6\frac{1}{2}$ "		— "	-
"	" common	"	— "		500 to 900 "	$\frac{1}{4}$
"	" large	"	— "		1120 "	$\frac{1}{3}$
"	lead	"	5 "		700 "	$\frac{1}{48}$
"	zinc, 15 ounce	"	1_8 "		— "	$\frac{1}{48}$
"	copper	"	— "		100 "	$\frac{1}{48}$
"	thatch	"	— "		— "	$\frac{1}{2}$

The last column shows what the height of the roof, in parts of the span, is usually made. As the timbers employed are of course less in dimension as the weight decreases, it follows that a much less quantity of timber is requisite where the metals can be employed. On *flats* it will be necessary to consider the weight of the number of persons who may be probably standing on it at a time. The force of the wind has been considered in par. 1592*a*. When the rise or pitch is $\frac{1}{6}$th of the span, the angle formed is 18°25″; $\frac{1}{4}$ is 26°35″; $\frac{1}{3}$ is 33°42″; $\frac{1}{2}$ is 45°; $\frac{2}{3}$ is 53°; $\frac{3}{4}$ is 56°20″; when equilateral, 60°; a whole pitch is 63°30″.

2041. By a study of the roofs which follow as examples, the architect will be led to other expedients and modifications of the forms submitted to his notice, as circumstances may call forth his ingenuity and talents. We have, we trust, already said enough to lead him on. Where economy must be consulted, the roof shown in *fig.* 690. may be used; it is only fit for a small building, and the span of such a one should not exceed 25 feet. The left end of the collar beam exhibits what is called the *carpenter's boast*, but it partakes somewhat of the rule joint; being worked out to a centre. But in roofs above 25 feet span it is not well to omit the king-post and tie beam, though, if particular strains are to be provided

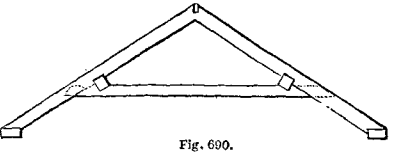

Fig. 690.

against, even in such small spans the struts should not be omitted, and the form shown in *fig.* 691. should be adopted, which will answer for spans at least up to 35 feet. In this and

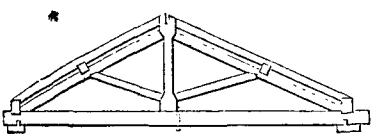

Fig. 691.

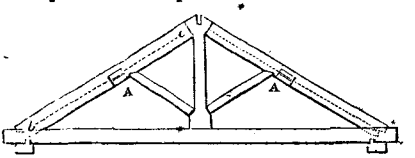

Fig. 692.

other cases of larger span, it is often desirable that the common rafters should not stand above the principals, and then the purlines are framed by mortices and tenons into the principals, as shown at A, *fig.* 692., wherein the line *bc* shows the underside of the common rafters notched on to the purlines. This is a usual practice in Gothic roofs.

2042. From 35 to 45 feet, the tie beam should be suspended from at least three points, or it will be unnecessarily heavy; and this suspension of the tie beam, so that it may be really a tie unsusceptible of alteration in form, is the true cause of this introduction of king and queen posts, as before explained. Indeed, as a general rule, it is well that the distance between such points of support for a tie beam should not exceed 13 to 15 feet, without expedients being used to prevent intermediate sagging. *Fig.* 693. is a queen-post roof of a span of 43 feet, over the railway workshops at Worcester, showing the introduction of skylights. The trusses are placed 15 feet apart. The principal rafters are 8 by 8; tie beam, 12 by 8; queen-post, 8 by 6; struts, $4\frac{1}{2}$ by $4\frac{1}{2}$; straining beam, 9 by 8; common rafters, $4\frac{1}{2}$ by 2; purlines, in two flitches each (trussed with stirrup pieces and iron ties), 9 by 3. The tie beams are carried on iron shoes. *Fig.* 694. is a queen-post truss for a span of 50 feet, which leaves a considerable space free in the middle. The tie beam will probably be scarfed, which will be best made between *a* and *b*. The straining sill *c*, strapped to the tie beam, will add materially to its strength.

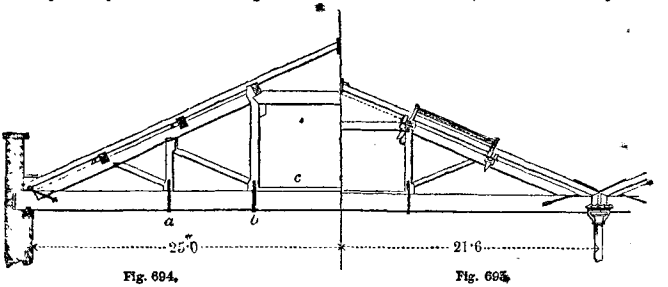

Fig. 694. Fig. 693.

2043. For spans above 60 feet we have not given scantlings of timber in the preceding tables; but such do not greatly increase beyond 60 feet with practicable spans, and enough has been already said to make the reader acquainted with that part of the subject. *Fig.* 695. is the truss of the parish church of Elgin, designed by A. Simpson, of Aberdeen. The trusses are placed 6 feet 6 inches from centre to centre. The tie beam is in two flitches, each 13 by $5\frac{1}{2}$; principal rafters, 11 inches deep at lower end, 8 inches at top, and 6 inches thick; collar beam, 7 by $5\frac{1}{2}$; king-post struts, 5 by $5\frac{1}{2}$; struts, 5 by $4\frac{1}{2}$; horizontal rafters, $4\frac{1}{2}$ by $2\frac{1}{2}$, placed 13 inches apart, and covered with inch grooved and tongued deal, and 7 lbs. lead. This is similar to the Italian system intimated in SPECIFICATIONS, par. 2285. The tie beams have cast iron shoes at each end, with abutments formed for the rafters, and secured with $\frac{7}{8}$ inch diameter bolts with nuts and washers. The wrought iron suspending rods are inch square, and have abutment pieces for the rafters and struts.

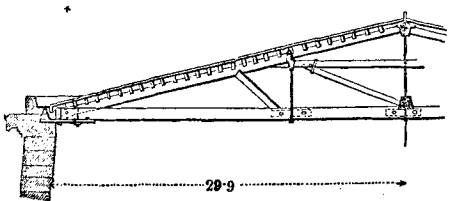

Fig. 695.

2043*a*. *Fig.* 695*a*. is the truss of a roof for a span of 45 ft., with cast iron shoes as abutments for the timbers acting as struts. The end of the tie beam has a cast iron shoe, which also takes the foot of the principal rafter. The sole plate of the shoe is prolonged inwards, to admit of its being secured by bolts to the tie beam. The head of the principal rafter *a*, and the end of the straining beam *a b*, are inserted into a cast iron socket, shown in detail in *fig.* A. The suspension rod passes through the solid part of the socket; it has a head at its upper end, and at its lower end it is screwed and secured by a nut. On the side of the socket is cast a rest, *c*, for the side of the purline. To avoid cutting the principal

rafters, the other purline at B is also carried in a cast iron rest bolted to the rafter. The centre suspending rod passes through a cast iron socket, which serves as an abutment to the main struts. Similar abutments are provided for the lower end of the struts. *Fig. 695b.*

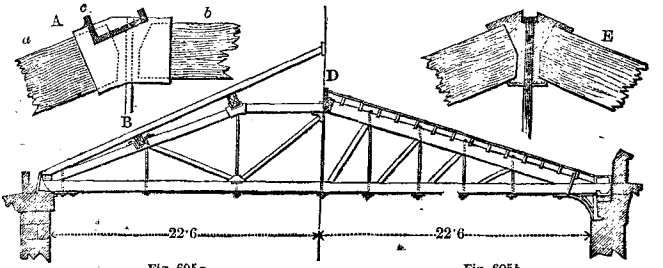

Fig. 695*a*. Fig. 695*b*.

for a span of 45 feet, has also wrought iron suspension rods. A roof of this description, 54 feet span and 212 feet long, is erected at the passengers shed of the Croydon railway station. The figure E is a section through a cast iron socket taking the heads of the principals, and through which passes a wrought iron king bolt, shown in position at D.

2044. In all the cases given, the roof is supposed to receive no support from any but the external walls, and the trusses to be in most cases not more than 10 feet apart.

2045. The reader who desires to become acquainted with other examples, is recommended to the works by Krafft, *Art de la Charpente*, and *Charpenterie*; Rondelet, *L'Art de Bâtir*, and its continuation by Blouet; Emy, *Art de la Charpenterie*; Tredgold, *Carpentry*; Newland, *Carpenter's and Joiner's Assistant*, to which work we are indebted for the above new examples; and *The Doctrines of Carpentry Explained—of a Roof*, by Lieut.-Col. Waddington, in the Papers of the Corps of Royal Engineers, 1849, x. 71–152.

2046. *Fig. 696.* represents a roof designed by J. Gibbs. From the centres of columns the

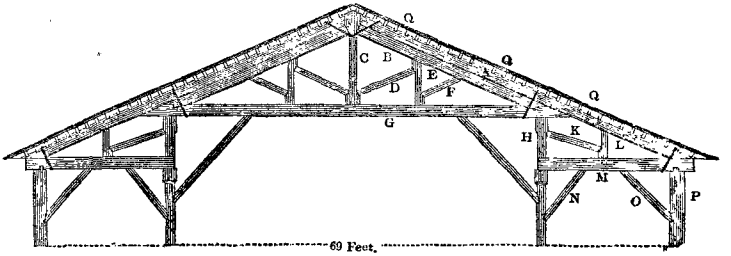

Fig. 696. ST. MARTIN'S-IN-THE-FIELDS, WESTMINSTER.

middle aisle is 39 ft. 11 in. The roof is well contrived and framed; but the timbers are stronger than they need have been. The scantlings are as follow:—A, principal rafter, 13 in. by 10 at bottom, and 11 in. by 10 at top; B, straining brace, 14 in. by 10 at bottom, and 11 in. by 10 at top; C, king-post, 9 in. by 9; D, strut, 7 in. by 7½; E, queen-post, 8 in. by 9½; F, strut, 7 in. by 7; G, tie-beam, 14 in. by 9½; H, post over the column, 14 in. by 9½; I, brace, 7 in. by 7; K, brace, 7 in. by 7; L, post, 8 in. by 9; M, hammer beam, 14 in. by 9½; N, brace, 8 in. by 8; P, post in the wall; QQQ, purline rafters, 4 in. by 6.

2047. *Fig. 697.* is the section of a roof by James Stuart, about 1785. The span is 51 ft., and as a variation from the general forms of roofs, it is worth the student's attention. The

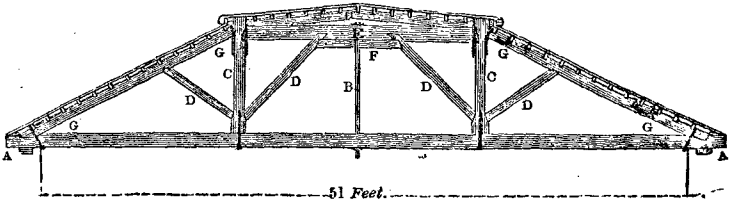

Fig. 697. GREENWICH HOSPITAL.

scantling of the timbers are subjoined. The distance between the trusses is about 7 ft. All the joints are well secured with iron straps. AA, tie-beam, whose whole length is 57 ft., 51 ft. clear between the walls, 14 in. by 12 in.; B, an iron king-post, 2 in. square; CC,

queen-posts, 9 in. by 12; DDDD, struts, 9 in. by 7; E, straining beam, 10 in. by 7; F, straining piece, 6 in. by 7; GG, GG, principal rafters, 10 in. by 7; *hhhh*, &c. purline rafters for boarding upon instead of rafters; H, a camber beam, supporting the platform.

2048. *Fig.* 698. exhibits the roof of the old Drury Lane Theatre, which was built in

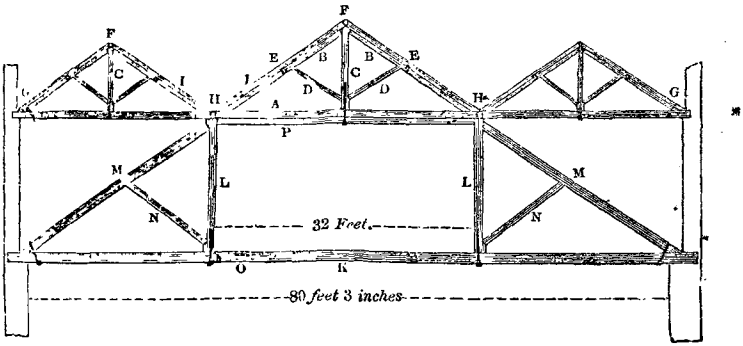

Fig. 698.

1793. It possesses great merit, from the simplicity of its composition and the accommodation afforded in the middle space for the carpenters and painters. By dividing the breadth of the building into three parts, the roof was kept low, and the scantlings much reduced in size. The span is 80 ft. 3½ in., the trusses were 15 ft. apart, and the whole length of the roof was 200 ft. It was destroyed by fire on the 24th of February, 1809. The scantlings of the timbers were as follow: — A, beams, 12 in. by 7; B, principal rafters, 7 in. thick; C, king-posts, 12 in. by 7; D, struts, 5 in. by 7; E, purlines, 9 in. by 5; F, ridge pieces, 1¼ in. thick; G, pole plates, 5 in. by 5; H, gutter plates framed into beams, 12 in. by 6, I, common rafters, 5 in. and 4 in. by 2½; K, beams, 15 in. by 12; L, posts, 15 in. by 12. M, principal braces, 14 in. by 12 and 12; N, struts, 8 in. by 12; O, oak trusses to the middle bearing of beams, 5½ in. by 4½; P, straining beams, 12 in. by 12.

2049. The last example we shall present is of the method in which the external dome of St. Paul's is framed (*fig.* 699.). The internal dome A*a* is of brickwork, two bricks thick, having, at every five feet, as it rises, a course consisting of bricks eighteen inches long, which serves to bind the whole thickness together. This dome was turned upon a centre, which rested upon the projection at its springing, without any support from below, and was afterwards left for the use of the painter. It was banded together with iron at the springing. Exterior to the brick dome (which has indeed, nothing immediately to do with the subject) is a cone of brickwork BB*b*, 1 foot 6 inches in thickness, plastered and painted, part whereof is seen from the pavement under the cupola through the opening *a*. On this cone BB*b* is supported the timber work which carries the external dome, whose hammer beams CC, DD, EE, FF are tied into the corbels G, H, I, K with iron cramps, which are well bedded into the corbels with lead, and bolted to the hammer beams. The stairs which lead to the Golden Gallery on the top of the dome are carried between the trusses of the roof. The dome is boarded from the base upwards, hence the ribs are fixed horizontally at near distances to each other. The scantling of the curve rib of the truss is 10 in. by 11½ at the bottom, and 6 in. by 6 at the top. The sides of the dome are segments of circles, whose centres are not marked in the figure; and which, if continued, would meet at top, and form a pointed arch. Above the dome rises a lantern of Portland stone, about 21 feet in diameter, and 64 feet high, standing on the cone. The whole of this construction is manifest from the figure, which exhibits the inner and outer domes with the cone between them. The combination is altogether an admirable example of the mathematical skill and judgment of Sir C. Wren.

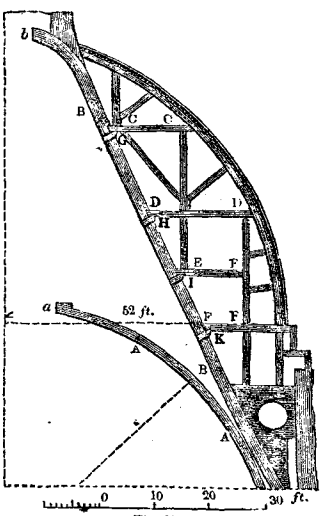

Fig. 699.

2050. The largest timber roof perhaps ever projected, was over a riding house at Moscow, in 1790, for Paul I. Emperor of Russia, the representation of which may be seen in Krafft, *Recueil de Charpente*. The span is 235 feet, and the slope with the horizon about 19°. The external dimensions of the building were 1920 feet long by 310 feet wide. It was lighted by a lantern at top, and had an interior gallery round the building for spectators. Cresy, in his *Civil Engineering*, states that this roof was never erected.

2051. We shall close this part of the section with a diagram (*fig.* 700.) of the roof of

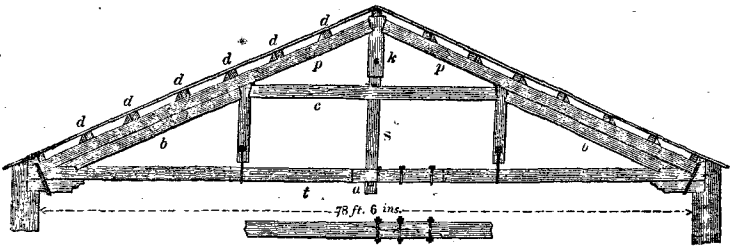

Fig. 700.

the basilica of S. Paolo fuori le mura, executed in the fifteenth century. The trusses are double, each consisting of two similar frames, nearly 15 inches apart, at intervals from each other of about 10 feet 6 inches. The principal rafters abut on a short-king post *k*. Between the trusses a piece of timber S is placed and sustained by a strong key of wood passing through it and the short king-posts. This piece sustains the beams by means of another strong key at *a*. The tie beams are in two lengths, and scarfed together, the scarf being held together by three iron straps. The scantlings of the timbers are as follow: beams *t*, 22½ in. full by nearly 15 in.; principal rafters *p*, 21¾ in. by nearly 15 in.; auxiliary rafters *b*, full 13¾ in. by full 13½ in.; straining beam *c*, near 15 in. by full 12¾ in.; purlines *d*, 8½ in. square and 5 ft. 7 in. apart; common rafters, full 5½ in. by 4½ in., and 8½ in. apart. The roof, which is constructed of fir, is nearly 78 ft. 6 in. span, and is covered with the Roman tile, the exact dimensions and form whereof will be found, under the head Tile, in the Glossary appended to this work. The roof is ingeniously and well contrived, and, with a different covering, would suit other climates. It was consumed by fire in the month of July, 1823. (275.)

Philibert Delorme, in his work entitled "*Nouvelles Inventions pour bien bâtir a petits Frais*," Paris, 1561, gives a mode of constructing domes without horizontal cross ties, when the springing of each rib is well secured at the foot. It is a very simple method, and of great use in domes, even of large diameter, the principle being that of making the several ribs in two or more thicknesses, which are cut to the curve in lengths not so great as to weaken the timber, and securing these well together by bolts or keys, and observing especially to *break* the joints of the several thicknesses. This method was adopted in the large Halle aux bleds at Paris, which was many years since destroyed by fire, and has been replaced by an iron-ribbed dome. The *fig.* 701. will explain the construction; and, if necessary, an iron hoop passed round at different heights will add much to the strength.

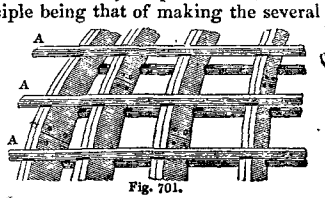

Fig. 701.

2052. The scantlings of the ribs, as given by Delorme, are as under: —

For domes of 24 feet diameter,	the ribs to be	8 in. deep, and 1 in. thick.
36 feet diameter,	—	10 in. deep, and 1⅓ in. thick.
60 feet diameter,	—	13 in. deep, and 2 in. thick.
90 feet diameter,	—	13 in. deep, and 2½ in. thick.
108 feet diameter,	—	13 in. deep, and 3 in. thick.

For small spans of about 24 to 30 ft., the inch plank is about 4 ft. long by about 8 in. wide. The feet of the ribs are tenoned into the wall plates; the shoulders of the tenons being about one inch. The ties A, placed about 2 feet distant, are 4 in by 1 in.; they are sometimes shown passing through the planks pinned with keys 1 in. thick and 1½ in. wide, and of a length nearly the width of the plank; this method tends materially to weaken the ribs; that shown in the cut is a better mode. The wall plates, 10 or 12 inches wide and 8 or 9 inches thick, have mortices 2 inches wide, 3 inches deep and 6 inches long, sunk at 2 feet apart, to receive the ends of the ribs. In a roof where the span was 64 feet, the scantling was increased to 13 inches wide and 1½ inches thick. The ties were alternately double and single, and were 3 inches by 1½; and each rib was double tenoned into the wall plate. This system, with many modifications, was extensively adopted in the

construction of the nave and side erections of the building for the Exhibition of 1862; and also for some of the passages, &c., of the Horticultural Society, where they still exist, and deserve examination. It is also adopted for temporary sheds of large spans.

2052*a*. This work by De Lorme deserves the study of every one that seeks to be an architect, though in these unfortunate days for the art the reward of study and reading is very doubtful.

2052*b*. Since the period of De Lorme, another system, arising out of it, has been extensively adopted for large buildings. Colonel Emy, having been called upon in 1819 to design a roof of 60 feet span, succeeded in composing one in which, while timbers of a greater length might be used, the necessary solidity, with the lightness and economy of the system of De Lorme, might be combined. This he carried out in 1825 and 1826. The workmanship is less than in De Lorme's roofs, as the wood is all in straight pieces, and is within the power of the ordinary carpenter. An arch is composed of a series of long and thin planks, laid flatways, the flexibility of which permits them to be easily and quickly bent without the aid of heat; and their rigidity, properly regulated, maintains the form given and destroys the thrust. *Fig.* 701*a*. is a portion of the base of one arc, which will illustrate the system. The details are best learnt from Emy's own work, as it would require much space to do justice to them. The vertical pieces A are $7\frac{3}{4}$ inches thick, and placed about 4 inches from the wall. The three first radial pieces B are prolonged beyond the uprights, and enter recesses in the wall to steady the frames. The plates C, breaking joint well with one another, compose the arc, and are $1\frac{3}{8}$ inch thick, $5\frac{1}{16}$ inches broad, and about 40 feet long, bolted together, the bolts being driven tightly into accurately made holes, and are further firmly tied together by iron straps; the bolts are $\frac{7}{10}$ inch diameter, and about 2 feet 6 in. apart; the principal rafters are $5\frac{1}{4}$ in. thick; the trusses are placed 9 feet 10 in. apart.

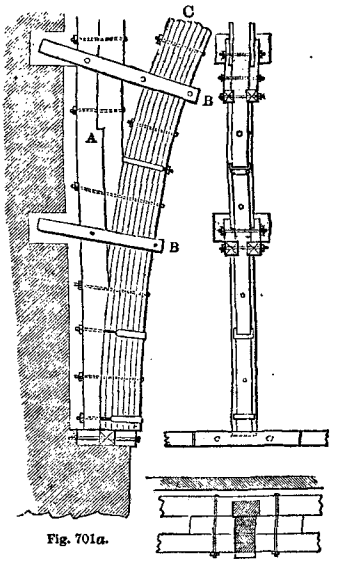

Fig. 701*a*.

2052*c*. Upon an experiment that was made by Emy to test the strength and thrust of this arch, he found it necessary to add a supplementary plate to a part of the extrados, and two plates to a part of the intrados. The following is the proportion of the number of plates and their width, which he adopted as a rule:—

		ft.	in.	
From the springing to radial (B) No. 1 - -	7 plates,	1	3	wide.
From radial No. 1 to the tie placed between radials Nos. 6 and 7 - - - - -	8 „	1	7	„
From this tie to radial No. 6 - - -	6 „	1	0	„
From radial No. 9 to the king-post - -	5 „	nearly 0	11	„

These supplementary plates were of oak, and of the same thickness as the others. These roofs are also given with sufficient detail in Newlands' work above-mentioned.

2052*d*. MEDIÆVAL ROOFS.—In the south of France the few Romanesque roofs did not differ from the common king-post roof, except in two points, viz., that the tie-beam and the king-post were stop-chamfered; and the strain of the purlines upon the principal rafter was counteracted by a nearly upright strut from the tie-beam. This system left the principal rafter with a false bearing, if the walls were not extremely thick in proportion to the width of the apartment which they enclosed. As a remedy, the late Romanesque builders tenoned the purline into the principals, and, moreover, laid it with its wider side to the rafters, in order that the backs of the common rafters should be flush with those of the principal rafters (*similarly to fig.* 692.). The next step was to put proper struts from the foot of the king-post. At the present day the purline is placed on edge for economy of material.

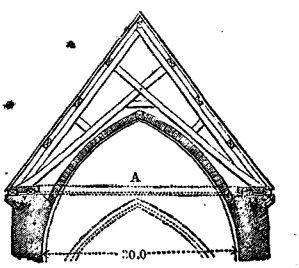

Fig. 701*b*.

2052*f*. In the north of France there was difficulty in roofing over the vaulting; either the main walls had to be carried as high as the ridge-rib, or else the frame of the roof had to be similar in principle to that shown in *fig.* 701*b*. Experience proved that the

latter scheme resulted in letting the principal rafters draw the tenons of the braces, and so destroy all idea of a tie connecting the two walls; hence the mediæval builders were obliged to raise the walls sufficiently high to allow the tie-beams to pass over the back of the ridge-rib, as would be the case at A. This was expensive, and, moreover, it was scarcely practicable where the walls were little thicker than was necessary for the backing to the formerets of the vaulting over the arches of windows. It is to these facts, rather than to any influence of climate, that may be attributed the adoption of the high-pitched roof, a system which required neither great width of footing nor large scantling of timber, for the purlines were discarded, and the weight was distributed among the rafters and trusses of each bay. The details of such a roof are simple. Two plates A (*fig.* 701*c.*) are placed with their widest sides on the wall, and are strutted between from the feet of the trusses to the centre of the bay. Upon these plates, tassels or short hammers B, are cocked down at intervals between the tie-beams, which are cocked down and dove-tailed, to take not only the feet of the common rafters, but also the nearly upright stud or ashlar rafter F, which serves to give a wider base to the principal and to the rafter. All these vertical pieces are double-tenoned and pinned into the other portions of the work.

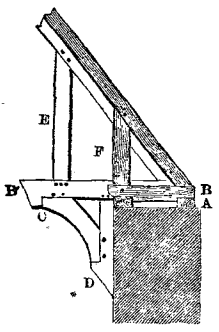

Fig. 701*c.*

2052*g*. The racking motion to which large roofs are liable, soon showed that this was not the manner in which to make them secure. The purlines had been discarded, but the need of their service remained; the necessity was obviated by erecting a sort of trussed partition under the ridge. If the king-post was *not* carried by the tie-beam, the whole roof depended upon the strength of the head of the king-post, into which the ridge was tenoned, and the manner in which it was connected with the ends of the principal rafters. It therefore appears to be more probable that the king-post was supposed to be carried by the tie-beam; indeed, examples occur of trussed partitions (*fig.* 701*d.*) to ridges, supported by king-posts A, which stand upon tie-beams that ride in queen-stirrups, B, where the stirrups are hung from the principal rafters at three-quarters of the height of the roof. Care has been given to this detail of the practice, because it seems to have been entirely mistaken by Viollet le Duc, *Dict.*: for example, the braces C, to the collars D, are supposed by him to exercise a favourable effect in preventing the flexure of the rafter outwards, whereas the fact would seem to be that the brace has to hold up the collar D and with it the stirrup B, and with them the tie-beam E, *for the collar is tenoned into the king-post and rafter.* That author defers dating the period of the perfection of mediæval carpentry (as well as of joinery) until the end of the 15th and the beginning of the 16th century.

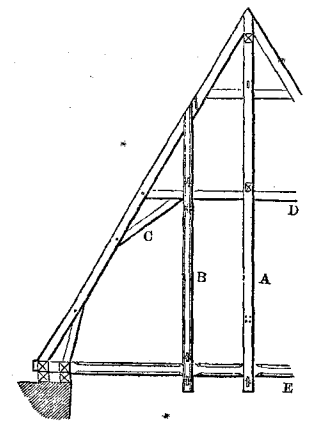

Fig. 701*d.* AT AUXERRE

2052*h*. The framing of cradle roofs, with king-posts carried upon (*not carrying*, as Viollet le Duc supposes) the tie-beams, became a practice that in France was general from the latter part of the 12th until the end of the 16th century, and which continued the same peculiarities of construction that are above indicated. The distinction between the stirrup and the post is less easy in the truss shown in *fig.* 701*e.*, but still it must be reckoned as a post; this example from the *préfecture*, formerly the episcopal palace, at Auxerre, covers a hall which is 30 feet wide; the trusses are placed 13 feet apart from centre to centre. The scantlings are as follows:—King-posts, 5 by 5, and principal rafters $5\frac{1}{2}$ by $4\frac{3}{4}$; the common rafters, 5 by $4\frac{3}{4}$, are shown in *fig.* 701*f.*, and are trussed in a different manner; they are placed nearly 2 feet apart. The roof appears to be boarded on the inside to the circular form.

2052*i*. Although Viollet le Duc is of opinion that the tie-beams to the fine cradle roof, 57 feet 3 inches span, constructed at the beginning of the 16th century, over the great hall of the *Palais de Justice*, at Rouen (*fig.* 247.), have been cut away, it may not be unfair to suggest that the work might have stood as well if, in its construction, it had resembled the older and fine roof of the château at Sully-sur-Loire, which he so well illustrates, but which want of space prevents our also doing. The student has, perhaps, no cause for regret, as its construction can scarcely be recommended for imitation in the present day. It is about 36 feet span.

2052*k*. The absence of a ridge-roll and the position of the ridge-piece in the majority

of mediæval roofs deserve notice. As soon as the purlines were discarded, it seems that builders relied upon the king-post to carry a ridge-piece upon which rested the ends of the rafters; these were halved and spiked together above it. Excepting in a few cases the ridge-piece was rather a purline at the top of the roof than an abutment. Much of the bolt and strap work applied in the visible frames of roofs is not always the most judicious as regards the conversion of construction into decoration. For example, if it were calculated that a tie-beam would sag, instead of increasing its scantling, or of trussing it, the mediæval carpenter would very probably hang it up to his truss, as in *figs.* 701*g.* and 701*h.* At a later period (say the 14th century) with some spikes. *Fig.* 701*k.* illustrates the method of forming the junction of post, beam, and strut in a roof; and *fig.* 701*l.* that of beams and posts in the timber framing of houses.

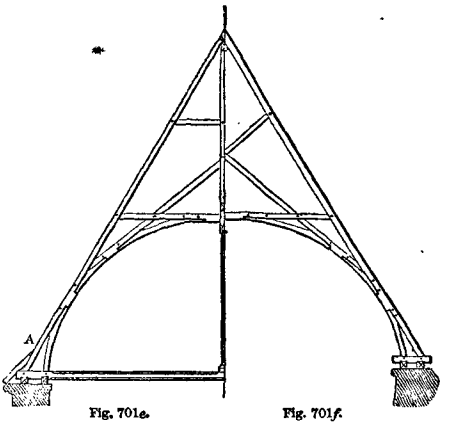

Fig. 701*e.* Fig. 701*f.*

2052*l.* It will be at once perceived, by *fig.* 701*c.*, that the *hammer-beam* BB′ takes the place of the tie-beam, the middle part of which may have been cut away. The tinted portion shows the foot of the rafters in a cradle roof; and the lighter portion the position and form of the hammer-beam, the outer end of which is tenoned and pinned on to the wall

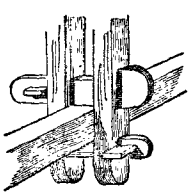

Fig. 701*g.*

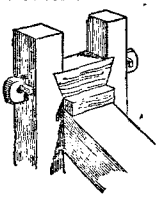

Fig. 701*h.*

Fig. 701*i.*

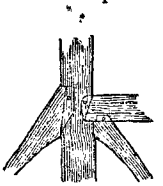

Fig. 701*k.*

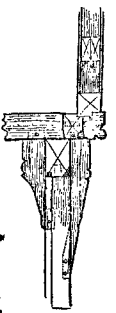

Fig. 701*l.*

plates A, and the inner end supported by a curved brace C, which starts from the bottom of the wall piece D, the whole being pinned together at the ends. Sometimes a corbel receives the foot of the wall piece and brace. Thus the whole length of the hammer beam may be said to have a solid bearing equal to supporting the roof rising above it, by the ashlar rafter or strut E, and at the same time forming a part of that structure. When the whole is put together securely, it has been considered almost impossible for hammer-beam roofs to spread, as from the stiffening action of the braces, it would require a very heavy force to push out the walls. But "the absence of that curved brace which distinguishes the Westminster example, makes these roofs much more likely to exert a thrust upon the walls, and, accordingly, it is notorious that in very many cases this has occurred. In the fine example at Croxton, the strain was so great as absolutely to break short off the perfectly sound heart of oak pins, nearly an inch in diameter, with which it was held together; and it is to be feared that many of the finest of these examples are similarly in a dangerous condition." So writes Mr. Street, in his *English Woodwork*, read at the Institute of British Architects in 1865, a paper which should not be neglected by the student. The principle of the construction of these roofs has perhaps not yet been satisfactorily elucidated.

2052*m.* The timber roofs in England may be divided into five classes:—I. Roofs with tie-beams; II. Roofs with trussed rafters, or single framed roofs; III. Roofs with braces with or without collars; IV. Roofs framed with hammer-beams; and V. Aisle roofs. The first are more general and better treated in France. The others are more peculiar to England, in which country elaborate examples of these forms are to be found, especially on the hammer-beam system.

2052*n. Pitch.*—These roofs are for the most part acutely pitched, though this was by no means their invariable characteristic. An angle of 90° was perhaps the ordinary elevation of Norman roofs, and in the early English period, though generally acutely pointed, roofs are nevertheless found of an equilateral pitch or angle of 60°, though this is of rare occurrence. In this and the succeeding style, examples are found of so low a pitch as to equal the flattest specimens of the perpendicular period. The roof, of the decorated

style, over the larger south aisle of St. Martin's Church, Leicester, has a span of 21 feet, with a rise of only 4 feet. (See *par.* 2040*b.*).

2052*o.* I. The *tie-beam* bears the whole weight of a low pitched roof. The roof over the south chapel of Kiddington Church, Oxfordshire, is of rather a steeper pitch than that at Leicester. The under side of the beam is well moulded, and is connected with the wall-pieces by moulded curved braces forming a very obtusely pointed arch; the purlines rest directly on the beam, and the ridge is supported on it by a post, and by short curved braces, the whole of the space above the tie-beam being filled up so as to give it the appearance of a solid triangular shaped beam. The naves of Raunds and of Higham Ferrers Churches, Northamptonshire, the latter of decorated date, and of Wimmington Church, Bedfordshire, present good and differing examples. The tie-beam is rarely left perfectly horizontal; the collar-beams and even the hammer-beams will be found to incline upwards. Tie-beams were sometimes employed quite independently of the other timbers, being simply laid across the building from wall to wall, notched down, and pinned to the wall plates. They were never entirely discarded, as they are to be met with in each of the four usually accepted divisions of the style. At Southfleet Church, Kent, the tie-beam is beautifully moulded; whereas, at Northfleet, it is left in almost its natural roughness, while the roof itself, which is one of the trussed rafter kind, is panelled, and has moulded ribs with carved bosses at the intersections.

2052*p.* An example of a strongly cambered tie-beam, with an ornamented king-post, is seen in Swardestone Church, Norfolk, and it is by no means uncommon in the counties of Kent and Sussex. The tie-beam of the roof over the aisle of North Walsham Church, Norfolk (*fig.* 701*m.*), passes through the nave wall, the end forming a corbel for the wall pieces of the nave roof. This roof also presents a practice which became almost universal in roofs of later date, viz., an intermediate truss between the tie-beams, in consequence of the extreme width between the main trusses, to support the ridge and purlines, by the adoption of double rafters on each side, strongly united and framed together, springing from a small hammer-beam over the apex of the arches. In roofs of high pitch, various endeavours were made to retain the arched shape in conjunction with the tie-beam. At Pulham Church, Norfolk, and Morton Church, Leicestershire, the beam divides the arch into two, with a bad result.

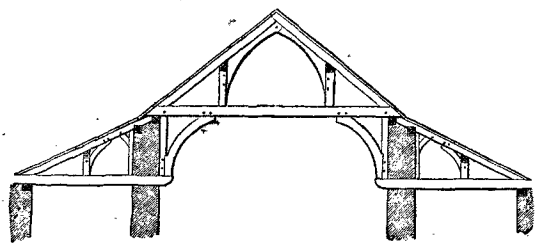

Fig. 701*m.* NORTH WALSHAM, NORFOLK.

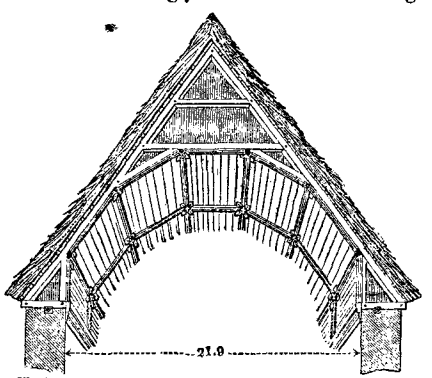

Fig. 701*n.* WIMBOTSHAM, NORFOLK.

2052*q.* II. *Single-framed roofs* sometimes have only diagonal braces connecting the rafters. These occur generally where the span is small, as over a porch. In wider spans, even without tie-beams, each pair of rafters was framed with a collar-beam, and was stiffened by braces crossing at times above the collar, and at others the braces being tenoned into its under side; when the latter was the case, a second collar was generally introduced above the first. Such roofs were very frequently boarded underneath, forming thus a polygonal barrel vault, and moulded ribs were applied, dividing the boarding into panels, with carved bosses at the intersections. The above details will be found combined in the examples of the decorated period from the nave of Wimbotsham Church, Norfolk (*fig.* 701*n*). The angle of the roof is 78°. The span is 21 feet 9 inches; the rafters and collars are 4½ inches by 4 inches. The former are placed 1 foot 9 inches apart between the centres. The nave roof of Reedham Church, Norfolk, 31 feet span, is framed on the same principle. The hall at Sully-sur-Loire is a fine example.

2052*r.* III. Roofs constructed with *braces* may be divided into two classes: I. Those with collar-beams and braces; and II. Those without collar-beams. An example of the former is seen in the roof of the nave at Pulham Church (*fig.* 701*o.*), which is formed at an angle of 105°, with a span of 20 feet 5 inches. Wall pieces A, are used, pinned into

the underside of the principal rafters, descending low down on the wall; the arched brace springs directly from this to the collar-beam, uniting them both with the principal. It is held that it would be impossible for this roof to spread until it had broken the curved braces. The various timbers are all effectively moulded. The principal rafters, 12 inches by 10 inches; common rafters, 6 inches by 3½ inches; collar-beam, 14 inches by 8½ inches; ridge piece, 8 inches by 8 inches; purline, 8 inches by 6½ inches; wall piece, 10 inches by 8½ inches. Width between centres of trusses, 6 feet 2 inches; and depth of cornice 3 feet 2 inches. Of class II. is the roof over the nave of Starston Church, Norfolk (*fig.* 701*p.*). The angle formed is 100°. At the apex of the roof is a strut B, about 9 inches square, which hangs down 2 feet; its four sides are morticed, two to receive the ends of the braces where they are pinned, thus preventing the possibility of its dropping; and the other two on the opposite sides, to receive the arched ridge braces, as shown at C. This arrangement tends to prevent the roof either spreading outwards, or rocking from east to west. The span is 21 feet 10 in. The principal rafters are 10 in. by 9 in.; common rafters, 6 in. by 4 in.; wall piece, 10 in. by 7½ in.; purline, 6½ in. by 5½ in.; and cornice, 11 in. by 10 in.

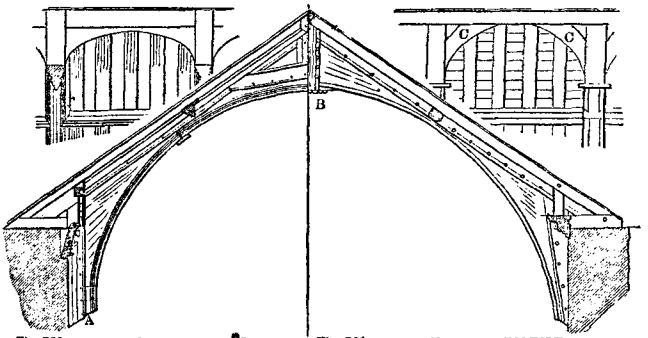

Fig. 701*o.* FULHAM, NORFOLK. Fig. 701*p.* STARSTON, NORFOLK.

2052*s.* IV. *Hammer-beam roofs* are always double-framed roofs, the rafters being supported by a skeleton framing of purlines and ridge, resting on, or framed into, the principal trusses. Among the many varieties of this description of roof may be noticed:—(1) Those with collar-beams and no struts, the collars, principals, and hammer-beams being united with curved braces; (2) Those in which the collar-beam is omitted, the curved braces being carried up almost to the ridge, and framed at the apex of the arch into a strut, which receives also the upper ends of the principals; (3) Those with no collars or struts, the whole of the truss being connected together and stiffened with curved braces only; in this instance the arched braces are formed of three pieces of timber, one on either side of the roof, tenoned into the hammer-beam and principal, and reaching up as far as the purline, the centre piece forming the apex of the arch, being tenoned into each principal, itself acting as a brace, and to a certain extent as a collar beam; and (4) Those having hammer-beams, collars, and struts, connected together with curved braces. (See *par.* 2052*l.*)

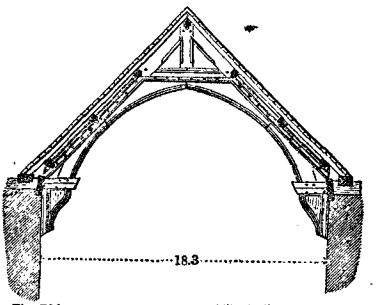

Fig. 701*q.* CAPEL ST. MARY, SUFFOLK.

2052*t.* An example of the first sort is the roof of Capel St. Mary's Church, Suffolk (*fig.* 701*q.*). The angle formed is 87°, and it is very seldom that a hammer-beam roof has a steeper pitch. The span is 18 feet 3 inches. The principal rafter is 10 inches by 8 inches; common rafter, 6 inches by 3 inches; hammer-beam, 10 inches by 8 inches; collar-beam, 10 inches by 8 inches; purlins, 6 inches by 5 inches; ridge piece, 6 inches by 6 inches. The trusses are 6 feet apart from centre to centre. The second sort is shown in *fig.* 701*r.*, the nave roof of Trunch Church, Norfolk. The intermediate trusses are the same, except that instead of the long wall-piece and brace, the wall-piece is stopped at the crown of the arch of the clearstory window, and a very depressed brace connects it with the hammer-beam. The spandrils are filled in with perforated tracery. The span is 19 feet. The principal rafter is 10 inches by 9 inches; common rafter, 6 inches by 4 inches; hammer-beam, 10 inches by 10 inches; purline, 8 inches by 5 inches; ridge piece, 10 inches by 10 inches. The trusses are 5 feet 6 inches apart. The third sort is shown in *fig.* 701*s.*, from the nave of Wymondham Church, Norfolk. The hammer-beams project rather more than a quarter the width of the nave, and are carved into figures; the intermediate trusses have also similar figures, but made subordinate to those of the main trusses. At the intersections of the purlines and ridge braces are large carved flowers standing out in bold relief. Of the

fourth sort, the most noted examples are those of Westminster Hall, 68 feet span (*fig.* 196.); Hampton Court, 40 feet span; Eltham Palace, 36 feet 3 inches; Beddington Hall;

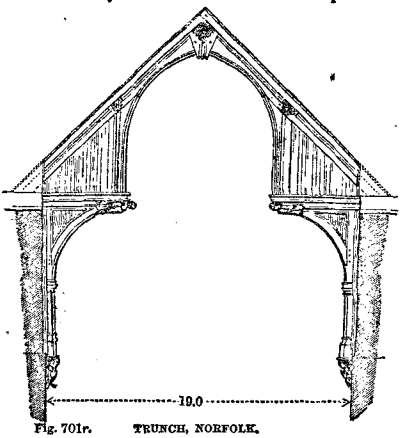

Fig. 701*r*. TRUNCH, NORFOLK.

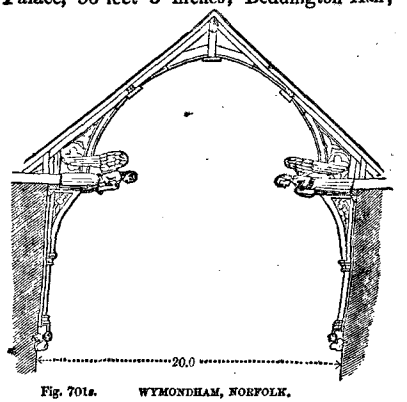

Fig. 701*s*. WYMONDHAM, NORFOLK.

South Wraxhall, 19 feet 9 inches; Croydon, 37 feet 9 inches, &c. It will be well to notice, what is not usually known, or shown, in the sections of the Westminster roof, that the main purlines over the strut, are upheld with the collar-beam by an intermediate rafter of great strength. Mr. S. Smirke has observed (*Archæologia*, xxvi. page 417–18), that "this roof is the common collar-beam roof, and of extremely simple construction; the whole pressure is carried by the straight lines of the principal rafter, and (curved) brace, above alluded to, directly into the solid wall, where it *ought* to be." The examples of lesser importance, as regards span, are not all of the same elegance as that of Westminster, which, at the same time that it is the largest and best, is also the earliest (1397) of the series. Some examples present double hammer-beams, forming a sort of corbelling over up to the ridge or to the collar-beam. *Fig.* 701*t*., from Knapton Church, Norfolk, is 32 feet span, and is a fair specimen of such roofs. The wall is 2 feet 10 inches in thickness. For all these examples, we are indebted to the excellent publication by Brandon, *Mediæval Roofs*, to which work we must refer the reader for details of decoration and painting, as the above figures are only here introduced to show the principles of construction displayed in such roofs.

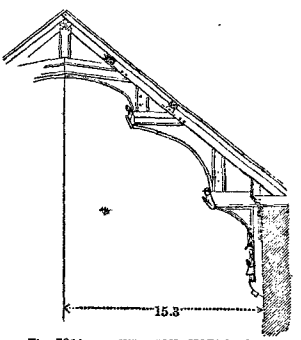

Fig. 701*t*. KNAPTON, NORFOLK.

2052*u*. In *fig.* 701*u*, we give the modern roof, of 31 feet 2 inches span, over the nave of Bickerstaffe Church, Yorkshire, designed by Sydney Smirke, R. A., as a good specimen of the adaptation of modern science to mediæval structures. The collar-beam is double, each 9 in. by 3 in., through which the king-post is tenoned and strapped. The purlines are 7 in. by 4 in.; the brace, 9 in. by 7 in.; and the corbels are 11 in. wide, being also tailed in 11 in.

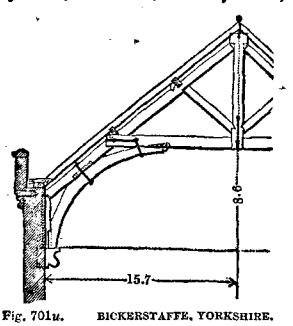

Fig. 701*u*. BICKERSTAFFE, YORKSHIRE.

2052*v*. V. *Aisle*, or *Lean-to*, *roofs*, may be described as usually consisting of strong timbers, answering the purpose of principal rafters, laid at each end on plates, the lower plate resting on the external wall, the upper one either supported on corbels projecting from the nave wall, or inserted therein. Wall-pieces are tenoned into the upper and lower extremities of the principals, and curved braces springing from the feet of these meet in the centre of the principal, forming a perfect arch, having the spandrils generally filled in with tracery. A purline is usually framed into the principal, and on this and the plates the common rafters are supported (see also *fig.* 701*o*.). In aisle roofs the whole of the timbers, even to the common rafters, were frequently found more richly moulded than those of the nave, possibly from being nearer the eye of the spectator.

2053. The following instructions relative to the lines necessary to be found in the framing of roofs are from Price's *British Carpenter*; and although published nearly 100 years, few subsequent works on this subject give more complete information. Let *abcd* (*fig.* 702.)

be a plan to be inclosed with a hipped roof, whose height or slope is Cb. Divide the plan lengthwise into two equal parts by the line *ef*, which produce indefinitely at both ends. Make *ag* equal *ea*, and *dk* equal to *df*; and through *k* and *g*, parallel to *ab* or *cd*, draw lines indefinitely *mo*, *lp*. With the distance dc or Cc, either of which is equal to the length of the common rafters, set off *qe*, as also from *k* to *p*, from *i* to *o*, and from *f* to *n*; from *k* to *m*, and from *g* to *l*. Make *ts* equal to Cb, and *ab* equal to *ta*, which points join; then either aC or *as* represents the length of the hip rafter, and joining the several lines *aqb*, *bpoc*, *cnd*, and *dmla*, they will be the *skirts* of the roof.

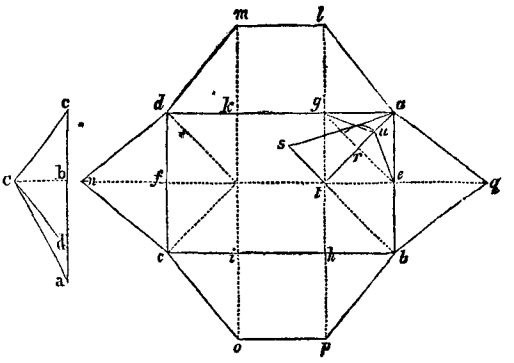

Fig. 702.

2054. To find the back of the hip. Join *ge*, and from *r* as a centre describe an arc touching the hip *as*, and cutting *at* in *u*. Then join *gu* and *ue*, and *gue* is the back of the hip rafter required.

2055. *Fig.* 703. represents, in *abcd*, the plan of a building whose sides are bevel to each other. Having drawn the central line *ef* indefinitely, bisect the angle *rag* by the line *ae*, meeting *ef* in *e*. From *e* make *eg* equal to *re*, and *rg* perpendicular to *ea*; then, if e a be made equal to *ea*, ra or *aq*, it will be the length of the hip rafter from the angle *a*. Through *e* and *f*, perpendicular to the sides *db*, *ca*, draw the lines *np*, *mq* indefinitely; and from *u*, as a centre with the radius *aq*, describe an arc of a circle, cutting *mq* in *q*, and *er* (perpendicular to *ba*) produced in *l*. By the same kind of operation *oc* will be found, as also the other parts of the skirts of the roof. The lines *nt*, *tfv*, and *vp* are introduced merely to show the trouble that occurs when the beams are laid bevel. The angle of the back of the hip rafter, *rwg*, is found as before, by means of *u* as a centre, and an arc of a circle touching *aq*. The backs of the other hips may be found in the same manner.

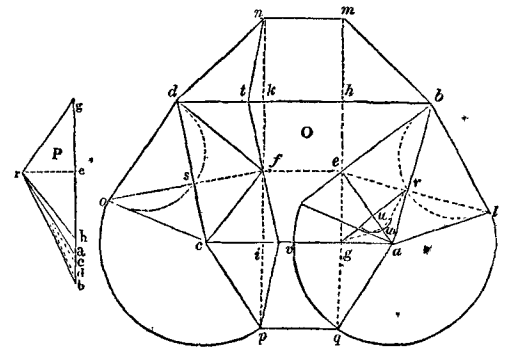

Fig. 703.

2056. *Fig.* 704., from Price's *Carpentry*, is the plan of a house with the method of placing the timbers for the roof with the upper part of the elevation above, which, after a perusal of the preceding pages, cannot fail of being understood. The plan F is to be prepared for a roof, either with hips and vallies, or with hips only. The open spaces at G and H are over the staircases: in case they cannot be lighted from the sides, they may be left to be finished at discretion. The chimney flues are shown at IKLMNO. Then, having laid down the places of the openings, place the timbers so as to lie on the piers, and as far as possible from the flues; and let them be so connected together as to embrace every part of the plan, and not liable to be separated by the weight and thrust of the roof. P is a trussed timber partition, to discharge the weight of the roof over a salon below.

2057. Q is the upper part of the front, and R a pediment, over the small break, whose height gives that of the blank pedestal or parapet S. Suppose T to represent one half of the roof coming to a point or ridge, so as to span the whole at once, "which," as Price truly observes, "was the good old way, as we are shown by Serlio, Palladio," &c., or suppose the roof to be as the other side U shows it, so as to have a flat or sky-light over the lobby F, its balustrade being W; or we may suppose X to represent the roof as spanning the whole at three times. If X be used, the valley and hip should be framed as at Y; if as T, the principal rafters must be framed as at Z, in order to bring part of the weight of the roof and covering on the partition walls. The remainder needs not further explanation

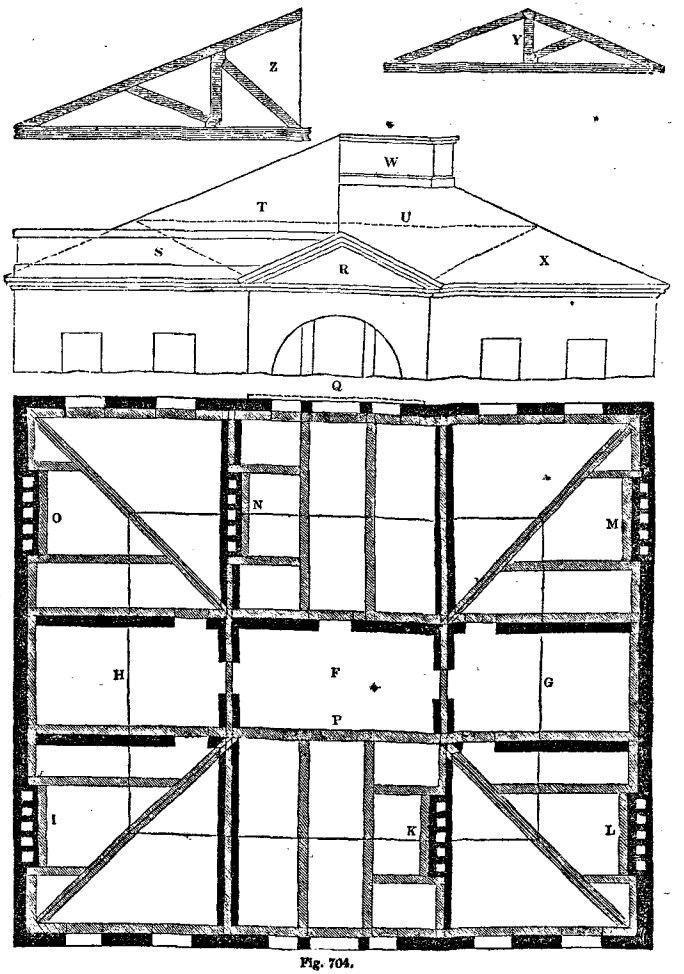

Fig. 704.

RIBS FOR GROINS, ETC.

2058. We shall now proceed to the method of forming the ribs for groined arches niches, &c. The method of finding the shape of these is the same, whether for sustaining plastering or supporting the boarding of centres for brick or stone work, except that, for plaster, the inner edge of the rib is cut to the form, and, in centering, the outer edge. Groins, as we have already seen, may be of equal or unequal height, and in either case the angle rib may be straight or curved; and these conditions produce the varieties we are about to consider.

2059. *To describe the parts of a groin where the arches are circular and of unequal height, commonly called* Welsh Groins. We here suppose the groin to be right-angled. Let AB (*fig.* 705.) be the width of the greater arch. Draw BD at right angles to AB, and in the straight line BD make CD equal to the width of the lesser arch. Draw DF and CE perpendicular to BD and EF parallel to BD. On AB describe the semicircle B*ghi*A, and on EF describe the semicircle E*qro*F. Produce AB to *p*, and FE to *m*, cutting A*p* in *y*. Through the centre *x* of the semi-

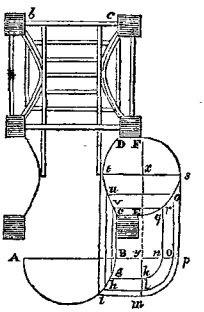

Fig. 705

circle EqrsF draw *ts* perpendicular to BD, cutting the circumference of the semicircle in *s*. Draw *sp* parallel to BD. From the centre *y*, with the distance *yp*, describe the quadrant *pm*. Draw *mi* parallel to AB, cutting the semicircle described upon AB in the point *i*. In the arc B*i* take any number of intermediate points *g*, *h*, and through the points *ghi* draw *it*, *hu*, *gv*, parallel to BC. Also through the points *ghi* draw *gk*, *hl*, *im* parallel to AB, cutting FE produced in *k* and *l*. From the centre *y* describe the arcs *kn*, *lo*, cutting AB produced in *mo*. Draw *nq*, *or*, parallel to BD, cutting the lesser semicircular arc in the points *q*, *r*. Through the points *q*, *r*, *s* draw *qv*, *ru*, *st* parallel to AB; then through the points *tuv* draw the curve *tuvc*, which will be the plan of the intersection of the two cylinders. The other end of the figure exhibits the construction of the framing of carpentry, and the method in which the ribs are disposed.

2060. To describe the sides of a groin when the arches are of equal height and designed to meet in the plane of the diagonals. Let *af* and *al* (*fig.* 706.) be the axes of the two vaults, meeting each other in *a*, perpendicular to *af*. Draw AB cutting *af* in *w*, and perpendicular to *al*, draw BG cutting *al* in *b*. Make *w*A and *w*B each equal to half the width of the greatest vault, and make *b*B and *b*G each equal to half the width of the lesser vault. Draw AH and BE parallel to *af*, and draw BH and DF parallel to *al*, forming the parallelogram DEHF. Draw the diagonals HD, FE. On the base AB describe the curve B*cdef*A, according to the given height *wf* of the required form, which must serve to regulate the form of the other ribs. Through any points *cde* in the arc B*cdef*A draw the straight lines *cq*, *dr*, *es* cutting the diagonal HD at *q*, *r*, *s*. Draw *qh*, *ri*, *sk* parallel to *al* cutting the chord BG at the points *x*, *y*, *z*, *b*. Make *xh*, *yi*, *zk*, *bl* each respectively equal to *tc*, *ud*, *ve*, *wf*, and through the points G*hikl* to B, draw the curve G*hikl*B. Draw *qm*, *rn*, *so*, *ap* perpendicular to HD. Make *qm*, *rn*, *so*, *ap* respectively equal to *tc*, *ud*, *ve*, *wf*, and through the points D, *m*, *n*, *o*, *p*, H draw a curve, which will be the angle rib of the groin to stand over HD; and if the groined vault be right-angled, all the diagonals will be equal, and consequently all the diagonal ribs may be made by a single mould.

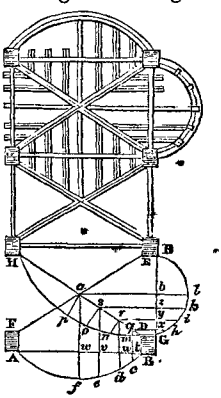

Fig. 706.

2061. The upper part of the above figure shows the method of placing the ribs in the construction of a groined ceiling for plaster. Every pair of opposite piers is spanned by a principal rib to fix the joists of the ceiling to.

2062. The preceding method is not always adopted, and another is sometimes employed in which the diagonal ribs are filled in with short ribs of the same curvature (see *fig.* 707.) as those of the arches over the piers.

2063. The manner of finding the section of an aperture of a given height cutting a given arch at right angles of a greater height than the aperture is represented in *fig.* 708.

2064. When the angle ribs for a square dome are to be found, the process is the same as for a groin formed by equal arches crossing each other at right angles, the joints for the laths being inserted as in *fig.* 707.; but the general construction for the angle ribs of a polygonal dome of any number of sides is the same as to determine the angle rib for a cove, which will afterwards be given.

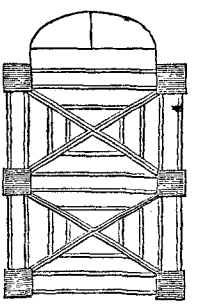

Fig. 707.

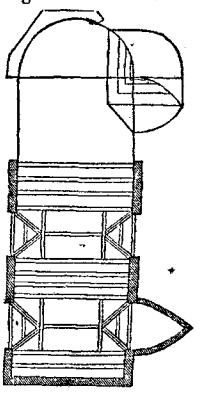

Fig. 708.

2065. When a circular-headed window is above the level of a plane gallery ceiling, in a church for example, the cylindrical form of the window is continued till it intersects the plane of the ceiling. To find the form of the *curb* or pieces of wood employed for completing the arris, let *dp* (*fig.* 709.) be the breadth of the window in the plane of the ceiling. Bisect *dp* in *h*, and draw *h*4 perpendicular to *dp*. Make *h*4 equal to the distance the curb extends from the wall. Produce 4*h* to B. Make

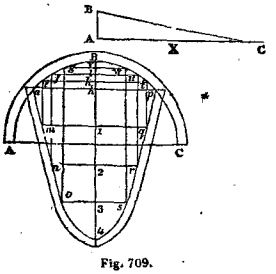

Fig. 709.

hB equal to the height of the window above the ceiling, and through the three points d, B, p describe the semicircle ABC for the head of the window. Divide hB into any number of equal parts, as 4 at the points k, l, v; and $h4$ into the same number of equal parts at the points 1, 2, 3. Through the points klv draw the lines et, fu, gw parallel to dp, and through the points 1, 2, 3 draw the lines mg, nr. os. Make $1m$, $2n$, $3o$ respectively equal to ke, lf, vg; as also $1q$, $2r$, $3s$ equal to kt, lu, vw; that is, equal to ke, lf, vg. Then through the points $dmno4$, and also through $pqrs4$, draw a curve which will form the curb required. In the section X of the figure, AC shows the ceiling line, whereof the length is equal to $h4$, and AB is the perpendicular height of the window; hence BC is the slope.

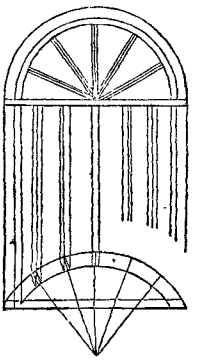

Fig. 710.

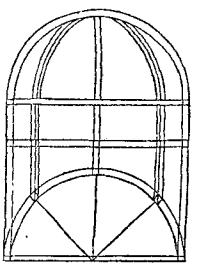

Fig. 711.

2066. The construction of a niche, which is a portion of a spherical surface, and stands on a plan formed by the segment of a circle, is simple enough; for the ribs of a niche are all of the same curvature as the plan, and fixed (*fig.* 710.) in planes passing through an axis corresponding to the centre of the sphere and perpendicular to the plane of the wall. If the plan of the niche be a semicircle (*fig.* 711.) the ribs may be disposed in vertical planes.

2067. In the construction of a niche where the ribs are disposed in planes perpendicular to the horizon or plan, and perpendicular to the face of the wall, if the niches be spherical all their ribs are sections of the sphere, and are portions of the circumferences of different circles. If we complete the whole circle of the plan (*fig.* 712.), and produce the plan of any rib to the opposite side of the circumference, we shall have the diameter of the circle for that rib, and, consequently, the radius to describe it.

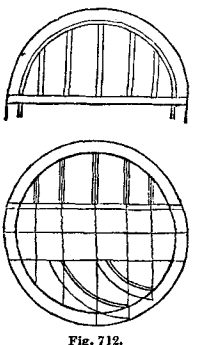

Fig. 712.

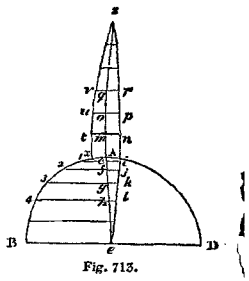

Fig. 713.

2068. *Of forming the boards to cover domes, groins, &c.* The principles of determining the developement of the surface of any regular solid have already been given in considerable detail. In this place we have to apply them practically to carpentry. The boards may be applied either in the form of gores or in portions of conic surfaces; the latter is generally the more economical method.

2069. *To describe a gore that shall be the form of a board for a dome circular on the plan.* Draw the plan of the dome ABD (*fig.* 713.), and its diameter BD and Ae a radius perpendicular thereto. If the sections of the dome about to be described be semicircular, then the curve of the vertical section will coincide with that of the plan. Let us suppose the quadrant AB to be half of the vertical section, which may be conceived to be raised on the line Ae as its base, so as to be in a vertical plane, then the arc AB will come into the surface of the dome. Make Ai equal to half the width of a board and join ei. Divide the arc AB into any number of equal parts, and through the points of division draw the lines $1i$, $2j$, $3k$, $4l$, cutting Ae in the points $efgh$ and ei in the points $ijkl$. Produce the line eA to s, and apply the arcs A1, 12, 23, 34 to Am, mo, oq in the straight line As. Through the points $mnoq$ draw the straight lines tn, up, vr, and make mn, op, qr, as also mt, ou, qv, respectively equal to ei, fj, gk; then through the points $inpr$ to s, and also through the points $xtuv$ to s, draw two curves from the points x and i so as to meet each other in s; and the curves thus drawn will include one of the gores of the dome, which will be a mould for drawing the boards for covering the surface.

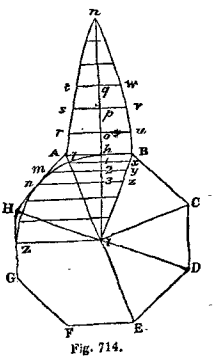

Fig. 714.

2070. In polygonal domes the curves of the gore will bound the ends of the boards; as, for example, in the octagonal dome

(*fig.* 714.), the plan being ABCDEFGH. Let *i* be the centre of the circle in which the octagon may be inscribed. Draw the half diagonal *i*A, *i*B, *i*C perpendicular to any side AB of the plan. Draw the straight line *ih*, cutting AB in *h*. Let *hlm*Z be the outline of one of the ribs of the dome, which is here supposed to be the quadrant of a circle. Divide the arc *h*Z into any number of equal parts from *h* at the points *lmn*, and through these points draw *lx*, *my*, *nz*, cutting B*i* at the points *xyz*, and *ih* at the points 1, 2, 3. Extend the arcs *hl*, *lm*, *mn*, on the line *hn*, from *h* to *o*, from *c* to *p*, from *p* to *q*, and through the points *opq* draw the straight lines *ru*, *sv*, *tw* perpendicular to *hn*. Make *ou*, *pv*, *qw*, as also *or*, *ps*, *qt*, respectively equal to 1*x*, 2*y*, 3*z*; then through the points A*rst* draw a curve, and through the points *uvw* draw another curve, meeting the former one in the point *n*. Thus will be formed the gore or covering of one side of the octagonal dome.

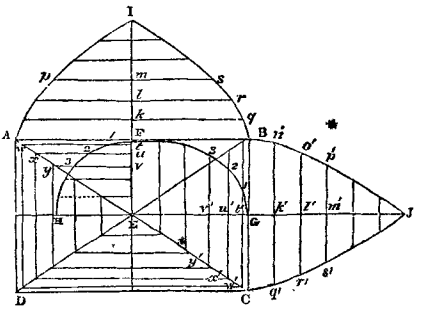

Fig. 715.

2071. When the plan of the base is a rectangle, as *fig.* 715., draw the plan ABCD and the diagonals AC and BD, cutting each other in E. Through E draw EI perpendicular to AB cutting AB in F, and through E draw EJ perpendicular to BC, cutting BC in G. Let the height of the dome be equal to half its breadth, and the section over the straight line EF a quadrant of a circle; then from the centre E describe the arc FH, its base being EF, and with the straight line EG as half the major axis of an ellipsis, and EF the minor axis, describe the quadrant GF of an ellipsis. Produce EF to I, and EG to J. Divide the arc of a quadrant FH from F into any number of equal parts, and extend the parts on the line FI to *klm*, through which draw the lines *kq*, *lr*, *ms*, &c. perpendicular to FI. Through the points 1, 2, 3, &c. draw *wt*, *xu*, *yv*, &c., cutting AE at *w*, *x*, *y*, and FE at *t*, *u*, *v*. Make *k'n'*, *l'o'*, *m'p'*, also *kq*, *lr*, *ms*, respectively equal to *tw*, *ux*, *vy*, and through the points *n'o'p'* draw a curve, also through the points *qrs* draw another curve meeting the former in I; then these two curves with the line AB will form the gore or boundary of the building of two sides of the dome. Also in the elliptical arc GF, take any number of points 1, 2, 3, and draw the lines 1*w'*, 2*x'*, 3*y'*, parallel to BC, cutting EC in the points *w'x'y'*, and GE in the points *t'*, *u'*, *v'*. Extend the arcs G1, 12, 23 from G*k'*, *k'l'*, *l'm'*, upon the straight line GJ, and through the points *k'l'm'* draw the lines *n'q'*, *o'r'*, *p's'*. Make *k'n'*, *l'o'*, *m'p'*, also *k'q'*, *l'r'*, *m's'* respectively equal to *t'w'*, *u'x'*, *v'y'*, and through the points B*n'o'p'* draw the curve BJ, and through the points C*q'r's'* draw the curve CJ; then BJC will be the gore required, to which the boards for the other two sides of the dome must be formed.

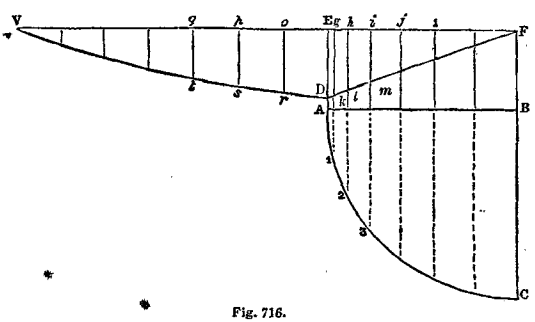

Fig. 716.

2072. A general method of describing the board or half gore of any polygonal or circular dome is shown in *fig.* 716. Let DE be half either of the breadth of a board or of one of the sides of a polygon, EF the perpendicular drawn from the centre. Draw the straight line AB parallel to EF, and draw EA and FB perpendicular to EF; then upon the base AB describe the rib AC of the vertical section of the dome. Divide the curve AC into the equidistant arcs A1, 12, 23, and through the points of division draw the lines 1*g*, 2*h*, 3*i* perpendicular to AB cutting EF at *ghi* and DF at *klm*. Produce FE to V and extend the arcs A1, 12, 23 upon the straight line EV from E successively to the points *opq*. Through the points *opq* draw the lines *or*, *ps*, *qt* parallel to ED. Make *or*, *ps*, *qt* respectively equal to *gk*, *hl*, *im*; then through the points *r s t* draw a curve, and DEV will be the half arc or half mould of the boarding.

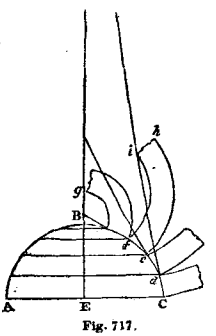

Fig. 717.

2073. *To cover a hemispherical dome by boards moulded to portions of conic surfaces.* Draw a vertical section of the dome ABC (*fig.* 717.) and divide the circumference into equal arcs *Cd, de, ef.* Through the centre E draw EB perpendicular to AC. Draw the chords *Cd, de, ef,* and produce all these chords till they meet the line EB, which they will produced in a convenient space; but those chords that are next to the bottom AC will require a distance too remote from AC; and for the present confining our attention to those chords which, when produced, would meet the line EB at a convenient distance from AC, let *ef* meet the axis EB produced in *g*, and from the point *g* as a centre with the distances *ge* and *gf* describe the arcs *eh* and *fi*. Then *efih* is the form of the board, so that its breadth is everywhere comprehended between the two concentric circles *eh* and *fi*, and when the boards are bent their edges fall on horizontal planes.

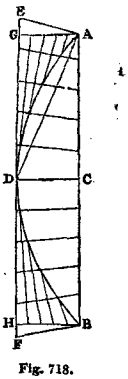

Fig. 718.

2074. We will here shortly repeat a method which has previously been given of describing an arc of a circle independent of its centre, as connected with this part of the subject, and useful in cutting out the boards of a dome where the centre is inaccessible or too distant for convenience. Let AB (*fig.* 718.) be the chord of the arc and CD its height in the middle. In this case AB will be bisected at C by the perpendicular CD. Draw the half chord AD, and perpendicular thereto draw AE, and through the point D draw EF parallel to AB; also draw AG and BH perpendicular to the chord AB cutting EF in the points G and H. Divide AC and ED each into the same number of equal parts, and draw lines through the corresponding points of division; these lines will converge, and if produced with the lines EA and FB, would all meet in one point. Divide AG into the same number of equal parts as the lines AC, ED, and from the points of division draw lines to the point D to intersect the former. A curve drawn through the points of intersection will form the arc of a circle. The other part DB is found in the same manner; and this is a convenient method, because any portion of a circle may be described within the width of a board.

2075. To find the relation between the height and the chord of the arc. Let *abc*, &c. (*fig.* 719.) be the middle points of the boards in the arc, and from *a* draw a line parallel to the base to meet the opposite curve; also from these points draw lines to the opposite extremity of the base; then each parallel is the base, as *fa*, and the distances *eg* intersected between it, and the point where the oblique line from its extremity cuts the middle vertical is the height of the segment.

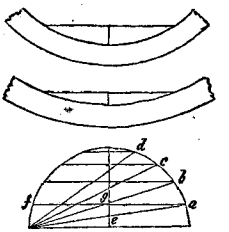

Fig. 719.

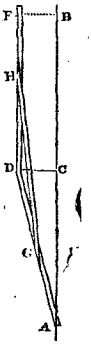

Fig. 720.

2076. It is, however, more convenient to describe the curvature of the board by a continued motion, which may be done as follows. Let AB (*fig.* 720.) be the chord of the arc. Bisect AB at C by the perpendicular CD, and make CD equal to the height of the segment. Draw DE parallel to AB, and make DE a little larger than AD; then form an instrument ADE with laths or slips of wood, and make it fast by a cross slip of wood GH. By moving the whole instrument, so that the two edges DA and DE may slide on two pins A and D, the angular point D of the instrument will describe the segment of a circle, and if the pin be taken out of A and put in the point B, the other portion DB of the segment ADB will be described in the same manner.

2077. The covering of an elliptical dome is formed by considering each part a portion of the surface of a cone. ABC (*fig.* 721.) is a vertical section through the greater axis of the base; the other vertical section through the axis at right angles being a semicircle; the joints of the boards therefore fall in the circumference of vertical circles.

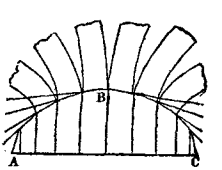

Fig. 721.

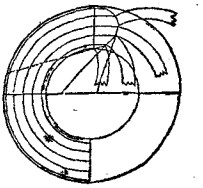

Fig. 722.

2078. In the same manner the covering of an annular vault whose section is semicircular is found, being on the same principles as now shown for a horizontal dome, which will be evident from an inspection of *fig.* 722.

BRACKETING.

2079. The pieces of wood which sustain the laths of cornices, coves, and the like, are called *brackets*, and they take in form the general outlines as nearly as possible of the forms to which they are to be finished.

2080. *A cornice bracket of any form being given, to make another similar one, or one that shall have the same proportions in all its parts.* Let ABCDEF (*fig.* 723.) be the given bracket. Draw lines from the angular points CDE, and let *Ab* be the projection of the required bracket. The lines AC, AD, AE, being drawn, draw *bc* parallel to the edge BC, cutting AC in *c*; draw *cd* parallel to CD, cutting AD in *d*. Draw *de* parallel to DE, cutting AE in *e*, and draw *ef* parallel to EF, cutting AF in *f*. Then *Abcdef* is the bracket required.

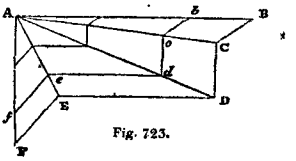

Fig. 723.

2081. *To form an angle bracket to support the plastering of a moulded cornice.* Let *fig.* 724. X be the plan of the bracket. Draw the straight line AE equal to the projection *ab* of the bracket on the plan X, and A*a* perpendicular to AE, to which make it equal. Join E*a*, and on AE describe the given form AFGHIKLE of the bracket which stands perpendicular to the line of concourse of the wall and the ceiling. From the angular points FGHIKL, draw the lines F*a*, G*b*, Ic, Hc, K*d*, L*d*, cutting AE in the points B CD, and *a*E in the points *a*, *b*, *c*, *d*. Draw *af*, *bg*, *ci*, *dk*, perpendicular to *a*E. Make *af*, *bg*, *ch*, *ci*, *dk*, *dl*, each respectively equal to AF, BG, CH, CI, DL, DK. Join *fg*, *gh*, *hi*, *ik*, *kl*, *l*E. Then *afghikl*E is the angle bracket required.

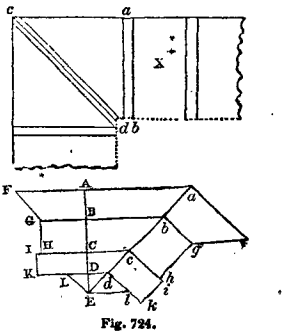

Fig. 724.

2082. An angle bracket for a cove (*fig.* 725.) may be described in exactly the same manner.

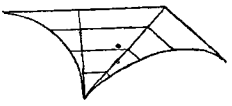

Fig. 725.

2083. When cove brackets have different projections, the method of describing the angle one is shown in *fig.* 726. Let AB, BC be the wall lines. Draw any line GD perpendicular to AB and HF perpendicular to BC. Make GD equal to the projection of the bracket from the wall represented by the line AB, and make HF equal to the projection of the bracket from the wall represented by BC. Then, as one of the brackets must be given, we shall suppose the bracket GAD described upon GD. Draw DE parallel to AB, and FE parallel to BC, and join BE. In the curve AD take any number of points Q, S, and draw QP, SR cutting GD in P, R and BE in *p*, *r*. From the points *p*, *r* draw the lines *pq*, *rs* parallel to BC, cutting HF in the points *p*, *r*. Draw *pq*, *rs* perpendicular to BE. Make *pq*, *rs* also *pq*, *rs* respectively equal to PQ, RS, &c. Ba and HC equal to GA, then through the points *aqs*, &c. draw a curve which forms the bracket for the angle. Also through the points C, *q*, *s* draw another curve, and this will form the cove bracket.

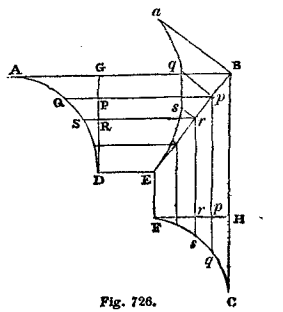

Fig. 726.

2084. The angle bracket of a cornice or cove may be formed by the method shown in X and Y (*fig.* 727.), whether the angle of the room or apartment be acute or obtuse, external or internal. Let ABC be the angle. Bisect it by the line BE. Draw GF perpendicular to BC, and make GF equal to the projection of the bracket, GC equal to its height, and FC the curve of the given bracket or rib. In the curve FC, take any number of points PQ, and parallel to BC draw the lines P*r*, Q*s*, cutting BE in the points *r*, *s*, and GF in the points R, S. Draw *rp*, *sq* perpendicular to BE, and make the ordinates *rp*, *sq* respectively equal to RP, SQ, and through all the points *pq*, draw a curve, which will be the bracket as required.

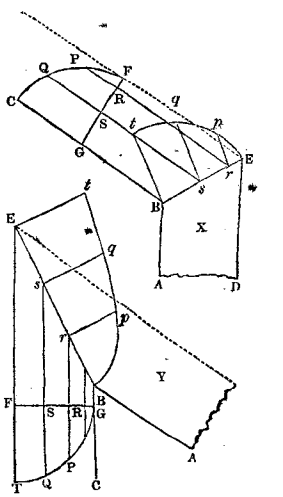

Fig 727.

2085. When the angle is a right angle, it may be drawn as at *fig.* 728., which is an ornamental bracket for the string of a stair, and traced in the same manner as that on a right-angled triangle.

2086. In coved ceilings, the coves meeting at an angle are of different breadths, and the plan of the angle is a curve to construct the brackets. Let ABC (*fig.* 729.) represent the angle formed by the walls of the room, and let B*defg* be the plan of the bracket in the angle of a curvilinear form. Draw HM, and thereon describe the bracket HOPQ intended for that side, and in the curve HOQ take any number of points NOP, and draw the lines NR, OS, PT perpendicular to AB, cutting it in the points R, S, T. Let MQ be the height of the bracket, and draw QA perpendicular to BA, and through the points NOPQ draw the straight lines N*d*, O*e*, P*f*, cutting HM at I KLM. Draw *hm* perpendicular to BC. Make *hr*, *hs*, *ht*, *ha* respectively equal to HR, HS, HT, HA, and draw *rn*, *so*, *tp*, *aq* perpendicular to BC; also from the points *defg* draw the lines *du*, *eo*, *fp*, *gq*, and through the points *hnopq* draw a curve, which will form the other bracket required.

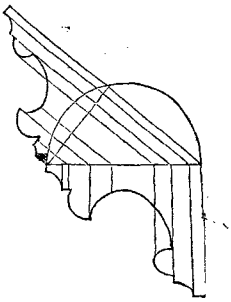

Fig. 728.

2087. Whether brackets occur in external or internal angles, the method of describing them is the same, and when the brackets from the two adjacent walls have the same projection, one of them must be given to find the angle bracket. When the brackets from these walls have unequal but given projections, then the form of one of the brackets must be given in form to find the angle bracket.

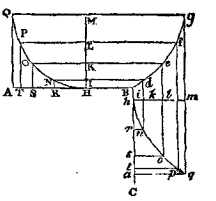

Fig. 729.

2088. *To form a bracket for a moulded cornice.* On the drawing of such cornice, draw straight lines, so as to leave sufficient thickness for the lath and plaster, which should in no case be less than three-fourths of an inch. Thus the general form of the bracketing will be obtained.

DOMES.

2089. We have, in a foregone page, mentioned a method of constructing domes with ribs in thicknesses. We here present to the reader two designs for dome-framing, wherein there is a cavity of framed work between the inner and outer domes; with moderate spans, however, simple framing is all that is required. *Fig.* 730. A is a design for a domical roof. B exhibits the method of framing the curb for it to stand upon, the section of the curb being shown upon *fig.* A. The design here given is nearly the same as that used for the dome of the Pantheon in Oxford Street, which was destroyed by fire. C is another design for a domical roof, which is narrow at the bottom part of the framing, for the purpose of gaining room within the dome.

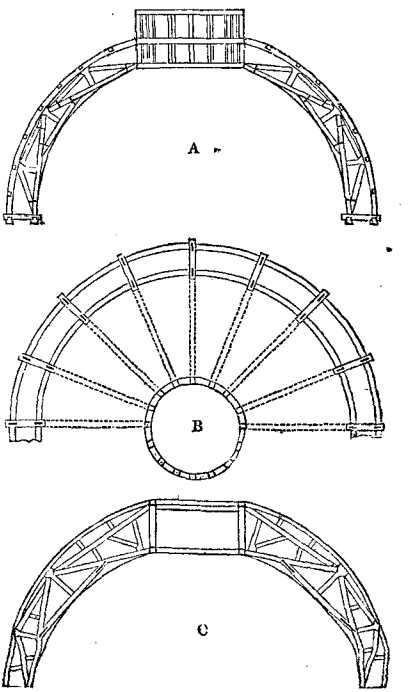

Fig. 730.

PENDENTIVES.

2090. If a hemisphere, or other portion of a sphere, be intersected (*fig.* 731.) by

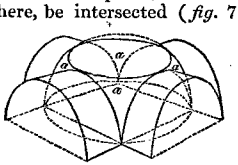

Fig. 731.

cylindrical or cylindroidal arches, vaults, *aa* are formed, which are called *pendentives*. The termination of these at top will be a circle, whereon may be placed a dome, or an upright drum story, which, if necessary, may be terminated by a dome.

The reader will immediately perceive that many varieties may be formed. Our object here is merely to show how the carpenter is to proceed in making his *cradling*, as it is called, when pendentives are to be formed in wood.

2091. *To cove the ceiling of a square room with conical pendentives.* Let ABC (*fig.* 732.) be half the plan of the room, and DFE the half plan of the curb, at whose top the ribs are all fixed. The hyperbolical arches *agb*, *bhc* on each of the four sides are of equal height. The straight ribs *bf*, *ik*, *lm*, &c. are shown on the plan by FB, IK, LM, &c. The method of finding the hyperbolical curves *agb*, *bhc* will be explained in the following figure.

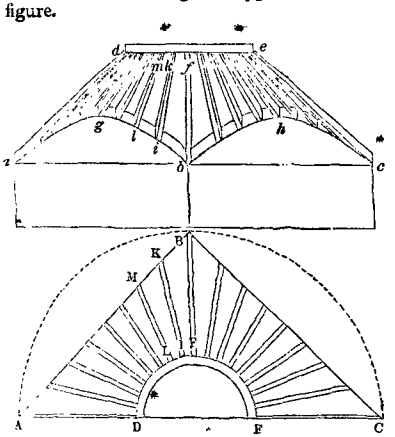

Fig. 732.

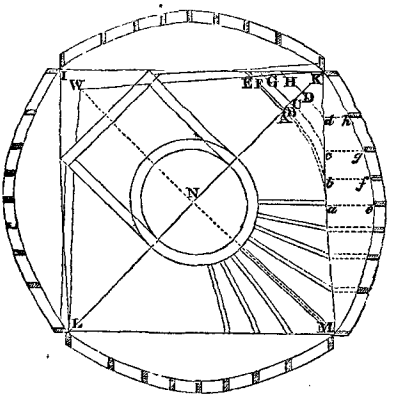

Fig. 733.

2092. *To find the springing lines of the preceding pendentives, the section in one of the vertical diagonal planes being given.* Bisect the diagonal LK (*fig.* 733.) at the point N by the perpendicular NW, which make equal to the height of the cone, and draw the sides LW and KW. Bisect the side MK of the square at *a*, and on N, with the radius N*a*, describe an arc *a*A, cutting the diagonal LK at A. Then take any points B, C, D, between A and K, and with the several radii NB, NC, ND, describe the arcs B*b*, C*c*, and D*d*, cutting KM at the points *d*, *c*, and *b*. From the points A, B, C, and D, draw AE, BF, CG, and DH perpendicular to the diagonal KL, cutting the side WK of the section of the cone at E, F, G, H. At the points *abcd* erect perpendiculars *ae*, *bf*, *cg*, and *dh* to the side ML, making each equal to their corresponding distances AE, BF, CG, and DH, which will be one half of the curve for that side from which the other may be traced. The dark parts show the feet of the ribs.

2093. *Fig.* 734. shows the method of coving a square room with spherical pendentives, which a few words will sufficiently describe. CD, DE are two sides of the plan; AFB is half the plan of the curb. In the elevation above is shown the method of fixing the ribs (which, in projection, are portions of ellipses) on two sides of the plan. *ab* is the elevation of the curb AFB; *cfd* and *dge* are ribs on each side of the plan supporting the vertical ribs that form the spherical surface, which vertical ribs support the curb *afb*. On *afb* may, if necessary, be placed a lantern or skylight; or, if light be not wanted, a flat ceiling or a dome may be placed. This pendentive is to be finished with plaster; hence the ribs must not be farther apart than about 12 inches.

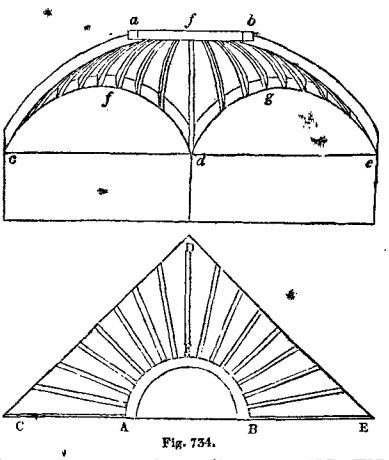

Fig. 734.

2094. For finding (*fig.* 735.) the intersection of the ribs of a spandrel dome, whose section is the segment of a circle, and whose plan is a square ABCD. Let DEFB be the section on the plane of the diagonal. First plan one quarter of the ribs, as at UC, TN, SL, RI, and QG, this last being parallel to DC or AB, the sides of the square; on V, with the radii VG, VI, VL, VN, and VC, describe the arcs G*Pg*, I*ti*, L*ul*, N*vn*, &c. cut-

ting the base DB of the angular rib in *g*, *i*, *l*, and *n*. Draw *gh*, *ik*, *lm*, and *no*, each perpendicular to DB, cutting the diagonal rib at *h*, *k*, *m*, and *o*. Then making the distances GH, IK, LM, and NO equal to the corresponding distances *gh*, *ik*, *lm*, and *no*, through the points H, K, M, O draw a curve which will be the under edge of that for the bottom of the ribs QG, RI, SL, TN, and UC, shown complete on each side of the square plan. If each of the circular segments on each side of the square plan be turned up at right angles to the plan ABCD, the ribs will then stand in their true position.

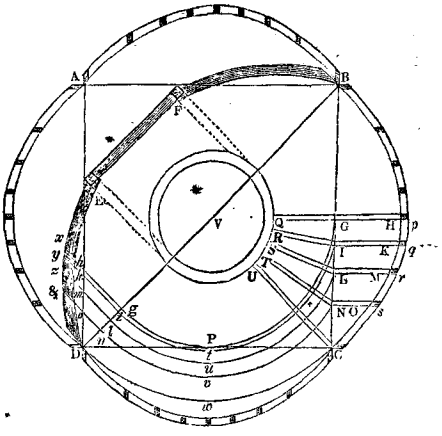

Fig. 735.

BRIDGES.

2095. We shall in this work confine ourselves to the simplest forms of timber bridges, which, as well as those of stone, will be found fully treated of in the *Encyclopædia of Engineering*, by Mr. Cresy, which forms one of the series. As they mostly depend on the principle of the truss, where the span is large, and this combination of timbers we have already explained; so in stone bridges the principle of construction of the arch is the chief matter for consideration, and to that a large portion of this work has been devoted; hence, on the part of the architect, we do not resign his pretension to employment in such works, for which, indeed, as respects design, his general education fits him better than that of the engineer.

2096. The bridge over the Brenta, near Bassano, by Palladio, is an example of a wooden bridge (*fig.* 736.), which is not only elegant as a composition, but one which is economical

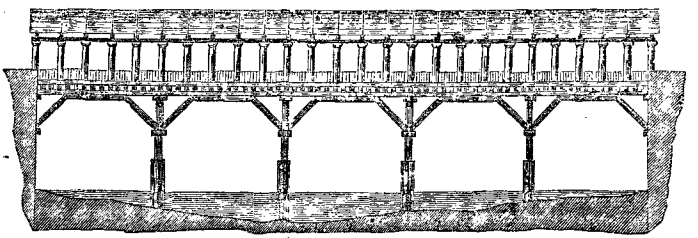

Fig. 736.

and might be employed with advantage where it is desirable that the piers should occupy a small space, and the river is not subject to great floods. The same great architect, in his celebrated *Treatise on Architecture*, has given several designs for timber bridges, the principles of whose construction have only been carried out further in many modern instances. He was the earliest to adopt a species of construction by which numerous piers were rendered unnecessary, and thus to avoid the consequences of the shock of heavy bodies against the piers in the time of floods. Of this sort was the bridge he threw over the rapid torrent of the Cismone (*fig.* 737.) whose span was 108 feet.

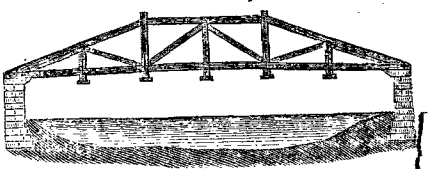

Fig. 737.

2097. Palladio has given a design for a timber bridge (*fig.* 738.) which is remarkable as having been the earliest that has come to our knowledge, wherein the arrangement is in what may be called framed voussoirs, like the arch stones of a bridge, a principle in later days carried out to a great extent, and with success, in iron as well as timber bridges.

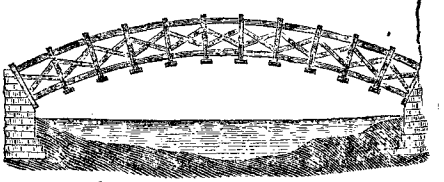

Fig. 738.

2098. We shall conclude our section on practical carpentry with a method of constructing timber bridges proposed by Price in his *Treatise on Carpentry*, and one not dissimilar in principle to the method of Philibert de Lorme, before mentioned. The bridge (*fig.* 739.) is supposed to consist of two principal ribs *ik*. The width of the place is spanned at once by an arch rising one sixth part of its extent. Its curve is divided into five parts, "which," says Price, "I purpose to be of good seasoned English oak plank, of 3 inches thick and 12 broad. Their joint or meeting tends to the centre of the arch. Within this rib is another, cut out of plank as before, of 3 inches thick and 9 broad, in such sort as to break the joints of the other. In each of these ribs are made four mortices, of 4 inches broad and 3 high, and in the middle of the said 9-inch plank. These mortices are best set out with a templet, on which the said mortices have been truly divided and adjusted. Lastly, put each principal rib up in its place, driving loose keys into some of the mortices to hold the said two thicknesses together; while other help is ready to drive in the joists, which should have a shoulder inward, and a mortice in them outward; through which keys being drove keep the whole together. On these joists lay your planks, gravel, &c.; so is your bridge compleat, and suitable to a river, &c. of 36 feet wide."

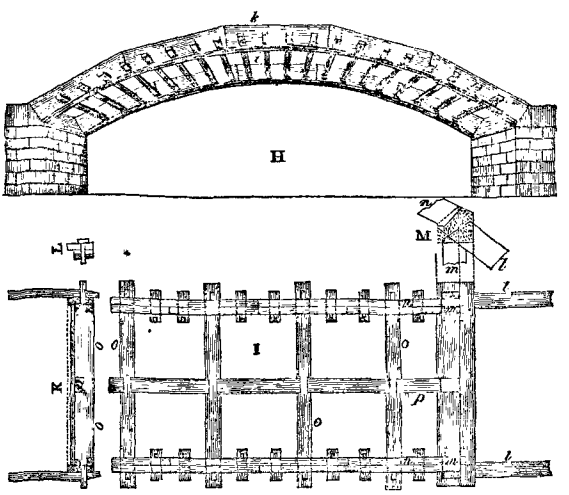

Fig. 739.

2099. "In case the river, &c. be 40 or 50 feet wide, the stuff should be larger and more particularly framed, as is shown in part of the plan enlarged, as I. These planks ought to be 4 inches thick and 16 wide; and the inner ones, that break the joints, 4 inches thick and 12 broad; in each of these are six mortices, four of which are 4 inches wide and 2 high; through these are drove keys which keep the ribs the better together; the other two mortices are 6 inches wide and 4 high; into these are framed the joists of 6 inches by 12; the tenons of these joists are morticed to receive the posts, which serve as keys, as shown in the section K, and the small keys as in L; all which inspection will explain. That of M is a method whereby to make a good butment in case the ground be not solid, and is by driving two piles perpendicularly and two sloping, the heads of both being cut off so as to be embraced by the sill or resting plate, which will appear by the pricked lines drawn from the plan I and the letters of reference." Price concludes: "All that I conceive necessary to be said further is, that the whole being performed without iron, it is therefore capable of being painted on every part, by which means the timber may be preserved; for though in some respects iron is indispensably necessary, yet, if in such cases where things are or may be often moved, the iron will rust and scale, so as that the parts will become loose in process of time, which, as I said before, if made of sound timber, will always keep tight and firm together. It may not be amiss to observe, that whereas some may imagine this arch of timber is liable to give way, when a weight comes on any particular part, and rise where there is no weight, such objectors may be satisfied that no part can yield or give way till the said six keys are broke short off at once, which no weight can possibly do."

SECT. V.

JOINERY.

2100. Joinery is that part of the science of architecture which consists in framing or *joining* together wood for the external and internal finishings of houses, such as the linings of walls and rough timbers, the putting together of doors, windows, stairs, and the like.

It requires, therefore, more accurate and nicer workmanship than carpentry, being of a decorative nature and near the eye. Hence the surfaces must be smooth and nicely wrought, and the joints must be made with great precision. The smoothing of the wood is called *planing*, and the wood used is called *stuff*, which consists of rectangular prisms roughly brought into shape by the saw, such prisms being called battens, boards, and planks, according to their breadth and thickness.

2101. We shall give but a succinct account of the joiner's tools; an acquaintance with their forms and uses being sooner learnt by mere inspection over a joiner's bench than by the most elaborate description.

TOOLS.

2102. The first is the *bench*, whose medium height is about 2 feet 8 inches, its length about 10 or 12 feet, and its width about 2 feet 6 inches. One side is provided with a vertical board, called the *side board*, pierced with holes ranged at different heights in diagonal directions, which admit of pins for holding up the object to be planed, which is supported at the other end of it by a *screw* and *screw check*, together called the *bench screw*, acting like a *vice*. The *planes* used by the joiner are the *jack plane*, which is used for taking off the roughest and most prominent parts of the stuff, and reducing it nearly to its intended form. Its *stock*, that is, the wooden part, is about 17 inches long, 8 inches high, and $3\frac{1}{2}$ inches broad. The *trying plane*, whose use is nearly the same as that last described, but used after it, the operation being performed with it by taking the shaving the whole length of the stuff, which is called *trying up*, whereas with the jack plane the workman stops at every arm's length. The *long plane*, which is used when a piece of stuff is to be tried up very straight. It is longer and broader than the trying plane, its length being 26 inches, its breadth $3\frac{5}{8}$ inches, and depth $3\frac{1}{8}$ inches. The *jointer*, which is still longer, being 2 feet 6 inches long, and is principally used for obtaining very straight edges, an operation commonly called *shooting*. With this the shaving is taken the whole length in finishing the joint or edge. The *smoothing plane*, which, as its name imports, is the last employed for giving the utmost degree of smoothness to the surface of the wood, and is chiefly used for cleaning off finished work. It is only $7\frac{1}{2}$ inches long, 3 inches broad, and $2\frac{3}{4}$ inches in depth. The foregoing are technically called *bench planes*.

2103. The *compass plane* which in size and shape is similar to the smoothing plane, except that its under surface or *sole* is convex, its use being to form a concave cylindrical surface. Compass planes are therefore of various sizes as occasion may require. The *forkstaff plane* resembles the smoothing plane in size and shape, except that the sole is part of a concave cylindric surface, whose axis is parallel to the length of the plane. The form is obviously connected with its application, and, like the last named, it is of course of various sizes. The *straight block* is employed for shooting short joints and mitres, instead of the jointer, which would be unwieldy: its length is 12 inches, its breadth $3\frac{1}{8}$ inches, and depth $2\frac{3}{4}$ inches.

2104. There is a species of planes called *rebate* planes, the first whereof is simply called the *rebate plane*, being, as its name imports, chiefly used for making rebates, which are receding planes formed for the reception of some other board or body, so that its edge may coincide with that side of the rebate next to the edge of the rebated piece. The length of the rebate plane is about $9\frac{1}{2}$ inches, its depth about $3\frac{1}{2}$ inches, and its thickness varies according to the width of the rebate to be made, say from $1\frac{3}{4}$ to $\frac{1}{2}$ inch. Rebate planes vary from bench planes in having no *tote* or handle rising out of the stock, and from their having no orifice for the discharge of the shavings, which are discharged on one side or other according to the use of the plane. Of the sinking rebating planes there are two sorts, the *moving fillister* and the *sash fillister*, whereof, referring the reader to the tool itself, a sight of which he can have no difficulty in procuring, the first is for sinking the edge of the stuff next to the workman, and the other for sinking the opposite edge, whence it is manifest that these planes have their cutting edges on the under side. Without enumerating many other sorts which are in use, we shall mention merely the *plough*, a plane used for sinking a cavity in a surface not close to the edge of it, so as to leave an excavation or hollow, consisting of three straight surfaces forming two internal right angles with each other, and the two vertical sides two external right angles with the upper surface of the stuff. The channel thus cut is called a *groove*, and the operation is called *grooving* or *plowing*. This species will vary according to the width from the edge; but it is generally about $7\frac{3}{8}$ inches long, $3\frac{5}{8}$ inches deep.

2105. *Moulding planes* are for forming mouldings, which, of course, will vary according to the designs of the architect. They are generally about $9\frac{3}{8}$ inches long, and $3\frac{5}{8}$ inches deep. When mouldings are very complex, they are generally wrought by hand; but when a plane is formed for them they are said to be *stuck*, and the operation is called *sticking*.

2106. The *bead plane* is used very frequently in joinery, its use being for sticking mouldings whose section is semicircular; when the bead is stuck on the edge of a piece of stuff to form a semi-cylindric surface to the whole thickness, the edge is said to be

beaded or rounded. When a bead is stuck so that it does not on the section merely fall in with its square returns, but leaves a space , thus, between the junctions at the sides, it is said to be *quirked*. The beads or planes vary from very small sizes up to the $\frac{3}{4}$ inch and $\frac{7}{8}$ bead. They may however be larger, and are sometimes stuck double and triple. The *snipebill plane* is one for forming the *quirk*, whereof we have spoken; but we do not think a detailed description of it necessary, more than we do of those which are made for striking *hollows* and *rounds*.

2107. The *stock and bit* is the next tool to be mentioned. Its use is for boring wood, and the iron, which varies as the size of the bore required, is made in a curve on its edge of contrary flexure so as to discharge the wood taken out. It fits into what is called the stock, which has a double curved arm working on spindles, the end opposite to the bit being pressed by the body, whose weight against the whole instrument is the power whereby the operation is performed. The bit is also called a *pin*, or *gouge bit*. It is an important tool, and much used. (See AUGER in *Glossary*.)

2108. *Countersinks* are bits for widening the upper part of a hole in wood or iron for the head of a screw or pin, and are formed with a conical head. *Rimers* are bits for widening holes, and are of pyramidal form whose vertical angle is about $3\frac{1}{2}$ degrees. The hole is first pierced by means of a drill or punch, and the rimer then cuts or scrapes off the interior surface of the hole, as it sinks downwards, by pressing on the head of the stock. According to the metal on which they are to be used they are differently formed.

2109. The *taper shell bit* is conical both within and without. Its horizontal section is a crescent, the cutting edge being the meeting of the interior and exterior conic surfaces. Its use is for widening holes in wood. Besides the above bits, there are some which are provided with a screw-driver for sinking small screws into wood with more rapidity than the unassisted hand will accomplish.

2110. The *brad awl*, the smallest boring tool, is so well known, that it would be waste of space to do more than mention it, the commonest of instruments in the science of construction.

2111. The variety of *chisels* is great. They are well known to be edge tools for cutting wood by pressure on it, or by percussion with a mallet on its handle. The *firmer chisel* is a tool used by the carpenter as well as the joiner for cutting away superfluous wood by thin chips. Those are best which are made of cast steel. If much superfluous wood is to be cut away, a strong chisel, with an iron back and steel face, is first used with the aid of the mallet, and then a slighter one with a very fine edge. The first is the *firmer* first mentioned, and the last is called a *paring chisel*, in the use whereof the force employed is from the shoulder or hand.

2112. The *mortice chisel*, whose use is for cutting out rectangular prismatic cavities in stuff is made of considerable strength. The cavity it so cuts out is called a *mortice*, and the piece which fits into it a *tenon*, whence the name of the tool. This chisel is one acted on only by the percussion of the mallet.

2113. The *gouge* is used for cutting concave forms in stuff. It is, in fact, a chisel whose iron is convex.

2114. The *drawing knife* is an oblique-ended chisel, or old knife, for drawing in the ends of tenons by making a deep incision with the sharp edge, guided by that of the tongue of a square, for which purpose a small part is cut out in the form of a triangular prism. The use of this excavation is to enter the saw and keep it close to the shoulder, and thus make the end of the rail quite smooth, for by this means the saw will not get out of its course.

2115. There are many species of the *saw*, which is a thin plate of steel, whose edge is indented with teeth for cutting by reciprocally changing the direction of its motion. The varieties are—the *ripping saw*, which is used for dividing or splitting wood in the direction of the fibres; its teeth are large, the measure being usually to the number of eight in 8 inches, such teeth standing perpendicularly to the line which ranges with the points: the length of the *plate* or *blade* of this saw is about 28 inches. The *half ripper* is used also for dividing wood in the direction of the fibres: the plate of this saw is as long as of that last described, but it has only three teeth in an inch. The *hand saw*, whose plate is 26 inches long, contains fifteen teeth in 4 inches; it is used for cross cutting, as in the direction of the fibres; for which purposes the teeth recline more than in the two former saws. The *panel saw* has about six teeth in an inch, the length of its plate being the same as the last; but in this and the hand saw thinner than in the ripping saw: it is used for cutting very thin wood, either with or across the fibres. The *tenon saw* is most used for cutting wood transverse to the fibres, as the shoulders of tenons. The plate of a tenon saw is from 14 to 19 inches long, having eight to ten teeth in an inch. This saw not being intended to cut through the whole breadth of the wood, and the plate being too thin to make a straight kerf, or to keep it from buckling, it has a thick piece of iron fixed on the edge opposite to the teeth, called the back. From the opening for the fingers through the

handle of this and the foregoing saws being enclosed all round, it is called a double handle. The *sash saw* is used for forming the tenons of sashes; its plate is 11 inches in length, having about thirteen teeth to the inch. It is sometimes backed with iron, but more frequently with brass. The *dovetail saw* is used for cutting the dovetails of drawers and the like; its plate is backed with brass, it contains fifteen teeth in about one inch, and is about 9 inches long. The handles of this and the last saw are only single. The *compass saw*, for cutting wood into curved surfaces, is narrow, thicker on the cutting edge as the teeth have no set, and is without a back; the plate, near the handle, is about an inch broad, and about a quarter of an inch at the other extremity, having about five teeth to the inch; the handle is single. The *keyhole*, or *turning saw*, in its plate resembles the compass saw, but the handle is long, and perforated from end to end for inserting the plate at any distance within the handle; there is a *pad* in the lower part of the handle, through which is inserted a screw for fastening the plate therein. As its name implies, it is used for turning out quick curves, as keyholes, and is therefore frequently called a keyhole saw.

2116. The teeth of all saws, except turning and keyhole saws, are bent alternately on the contrary sides of the plate, so that all the teeth on the same side are alike bent throughout the length of the plate, for the purposes of clearing the sides of the cut made in the wood by it. The saw is a tool of great importance in every case where wood is to be divided, for by its means it can be divided into slips or scantlings with no more waste than a small slice of the wood, whose breadth is equal to the depth of the piece to be cut through, and the thickness of it equal to no more than the distance of the teeth between their extreme points on the alternate sides of the saw measured on a line perpendicular to them; whereas, by any other means, such as the axe for instance, large pieces of timber could only be reduced in size by cutting away the superfluous stuff, which would be no less a waste of labour than of the material used; and even then it would have to be reduced to a plane surface.

2117. Joiners use the *hatchet*, which is a small axe, for cutting away the superfluous wood from the edge of a piece of stuff when the part to be cut away is too small to be sawed.

2118. The *square* consists of two rectangular prismatic pieces of wood, or one of wood, and the other, which is the thinnest, of metal, fixed together, each at one of their extremities, so as to form a right angle both internally and externally; the interior right angle is therefore called the inner square, and the exterior one the outer square. Squares are, for different applications, made of different dimensions. Some are employed in trying up wood, and some for setting out work; the former is called a trying square, and the latter a setting out square. To prove a square it is only necessary to reverse the blade after having drawn a line on the surface to which it is applied: if the line of the blade on reversal do not coincide with that first drawn, the square is incorrect.

2119. The bevel consists, like the square, of a blade and handle; but the tongue is moveable on a joint, so that it may be set to any angle. When it is required to try up many pieces of stuff to a particular angle, an immoveable bevel ought to be made for the purpose; for unless very great care be taken in laying down the moveable bevel, it will be likely to shift.

2120. The *gauge* is an instrument used for drawing or marking a line on a piece of stuff to a width parallel to the edge. It consists generally of a square piece with a mortice in it, through which runs a sliding bar at right angles, called the stem, furnished with a sharp point or tooth at one extremity, projecting a little from the surface; so that when the side of the gauge next to the end which has the point is applied upon the vertical surface of the wood, with the toothed side of the stem upon the horizontal surface, and pushed and drawn alternately by the workman from and towards him, the tooth makes an incision from the surface into the wood at a parallel distance from the upper edge of the vertical side on the right hand. This line marks precisely the intersection of the plane which divides the superfluous stuff from that which is to be used. When it is required to cut a mortice in a piece of wood, the gauge has two teeth in it, and is called a *mortice gauge*, one tooth being stationary at the end of the stem, and the other moveable in a mortice between the fixed tooth and the head; so that the distances of the teeth from each other, and of each from the head, may be set at pleasure, as the thickness of the tenon may require.

2121. The *side hook* is a rectangular prismatic piece of wood, with a projecting knob at the ends of its opposite sides. The use of the side hook is to hold a board fast, its fibres being in the direction of the length of the bench, while the workman is cutting across the fibres with a saw or grooving plane, or in *traversing* the wood, which is planing it in a direction perpendicular to the fibres.

2122. The *mitre box* consists of three boards, two, called the sides, being fixed at right angles to a third, called the bottom. The bottom and top of the sides are all parallel; the sides of equal height, and cut with a saw in two directions of straight surfaces at right angles to each other and to the bottom, forming an angle of 45 degrees with the sides. The mitre box is used for cutting a piece of tried up stuff to an angle of 45 degrees with two

of its surfaces; or at least to one of the arrisses, and perpendicular to the other two sides, or at least to one of them, obliquely to the fibres.

2123. The *straight edge* is a slip of wood made perfectly straight on the edge, in order to make other edges straight, or to plane the face of a board straight. It is made of different lengths, according to the required magnitude of the work. Its use is obvious, as its application will show whether there is a coincidence between the straight edge and the surface to which it is applied. When joiners wish to ascertain whether the whole surface of a piece of wood lies in the same plane, they use two slips, each straightened on one edge, with the opposite edge parallel, and both pieces of the same breadth between the parallel edges; whence each piece has two straight edges or two parallel planes. To find, therefore, whether a board is twisted, one of the slips is placed across one end and the other across the other end of the board, with one of the straight edges of each upon the surface. The joiner then looks in a longitudinal direction over the upper edges of the two slips, until his eye and the said two edges are in one plane; or otherwise the intersection of the plane passing through the eye and the upper edge of the nearest slip will intersect the upper edge of the farthest slip. If it happen as in the former case, the ends of the wood under the slips are in the same plane; but should it happen as in the latter, they are not. In the last case, the surface is said to *wind;* and when the surface is so reduced as for every two lines to be in one plane, it is said to be *out of winding,* which is the same as to say it is a perfect plane. From the use of these slips, they are denominated *winding sticks.*

2124. The *mitre square,* an instrument so called because it bisects the right angle or mitres the square, is an immoveable bevel, for the purpose of striking an angle of 45 degrees with one side or edge of a piece of stuff upon the adjoining side or edge of the said piece of stuff. It consists of a broad thin board, let or tongued into a piece on the edge called the fence or handle, which projects equally on each side of the blade, whereof one of the edges is made to contain an angle of 45 degrees with the nearest edge of the handle, or of that in which the blade is inserted. The inside of the handle is called the guide. The handle may be about an inch thick, 2 inches broad; the blade about $\frac{3}{16}$ to $\frac{1}{4}$ of an inch thick, and about 7 or eight inches broad. The *arris* of a piece of stuff is the edge formed by two planes.

MACHINERY.

2124*a*. In many of the operations of the joiner, where numerous copies of the same thing have to be produced, accuracy is ensured by introducing the principle of the *guide,* either to direct the tool over the work, or the work over the tool. The *mitre box, shoot blocks,* and the various kinds of *fences* and *stops,* are examples. The principle of the *guide* is also applied to simple sawing and planing, and to grooving, tonguing, morticing, tenoning, and shaping. The *circular saw* was introduced about the end of the last century into England, and attempts to construct a *planing machine* were made about 1776 and 1791 (G. L. Molesworth, *On the Conversion of Wood by Machinery,* read at the Institute of Civil Engineers, November 17, 1857). When Sir S. Bentham was in Russia previous to 1790, he had made considerable progress in contriving machinery for shaping wood, such as all the parts of a highly finished sash window; another for preparing all the parts of a wheel, so that the joiner or wheelwright in that case had only to put the several pieces together. In 1802 Bramah patented machinery for producing straight, parallel, and curvilinear surfaces on wood. In 1807 Brunel's famous block machinery was set in motion in Portsmouth dockyard. Thomson's machinery for sawing, gauging, grooving, and tonguing floor boards was in operation in 1826; and, in 1827, Muir of Glasgow patented a machine for working floor boards, which has since served as a model for others. This machine has approached perfection in that of MacDowall of Johnstone. A rack circular saw bench, for round or square timber, quickly converts a log or balk into square timber.

2124*b*. For the ordinary workshop, where the trade is limited and much varied, the simpler American machines are more suitable. The *saw bench* occupies little space and can be applied in plain and bevel sawing, and ripping, mitring, tenoning, rebating, &c. It is only 3 feet 2 inches long, 2 feet 2 inches wide, and 3 feet 6½ inches high; the saw is 8 inches in diameter and makes 15½ revolutions for each turn of the handle. A crank may be acted on by a treadle when the stuff is thin, but in ordinary cases the machine requires two operators. We cannot satisfactorily describe the details, without illustrations, of the many operations which this handy bench aids in performing with accuracy and dispatch. In Furness's patent wood working machine for planing, moulding, morticing, sawing, squaring, tenoning, boring, rebating, and grooving, the stuff is operated upon by cutters, held by horizontal arms fixed to a vertical shaft, in which it resembles the Bramah's machine of 1802, but it is much simpler and less expensive. Worssam's "general joiner" for the same purposes will, it is said, with a 2 horse-power, do the work of at least fifteen skilled joiners. Perin's patent French *band saw blades* are made from $\frac{1}{16}$th of an inch to 8 inches in width and up to 50 feet in length.

2124*c*. In machines with revolving cutters the general opinion is, that the greater the speed of the cutting tool the better will be the quality of the work. The practical limit,

however, appears to be between 2,500 and 3,500 revolutions per minute. A higher velocity heats the bearings, destroys the balance, and causes injurious vibrations. To produce a good result the travel of the work should be very slow relatively to the travel of the cutters. In some of the planing machines the cutters revolve with a velocity of 7,000 feet per minute, while the work advances at the rate of only 30 feet, but as a general rule the work travels about $\frac{1}{20}$th of an inch for each stroke of the cutters. To withstand this high velocity the framing of the machine requires to be perfectly constructed; the bearings made of a hard alloy, and precautions taken for obviating the wear of them. Newlands' work gives illustrations and detailed descriptions of some of the machinery.

2124*d*. Mention must be made, though space prevents a description, of Jordan's patent wood and stone carving machine invented about 1843, and worked by *Pratt in 1845 to 1850* on a large scale. It roughed out the material according to the design, leaving but little labour to be received from the hands of the carver. The invention has been *again taken up*. Moulded work was also for some time obtained by burning away the wood by applying red hot iron moulds to it. This system has quite exploded.

2125. In joiner's work executed during the 13th, 14th, and 15th centuries, the wood has neither warped, split, nor shrunk in the tenons and at other joints. This excellence is ascribed to the practice of seasoning the wood for at least six years after it was sawn; by first leaving it in damp places or even in water, and then stacking it on open piles under cover, when it was often turned and sometimes smoked; after such treatment the wood, when worked, has a tendency to acquire in the course of time the appearance of Florentine bronze.

2125*a*. As very old timber is likely to show shakes and to be worm-eaten, the mediæval joiners felled oak from two to three hundred years old; i.e., timber which, at a yard from the ground, measured from 66 or 72 to 120 or 126 inches in girt without the albumen, and commenced its conversion by marking it with one diameter crossing another at right angles. The cuts on these lines having been made, the quarters were sawn in various ways, regard being had, as much as possible, to the texture of the wood. An unseasoned log of oak splits as shown at A, *fig.* 739*a*. because the inner concentric circles are harder and more compact than the outer ones; therefore the latter, being the most extensive in surface as well as the most porous, contain a greater quantity of moisture, and shrink more than the inner ones in drying, thus causing splits or shakes leading to the centre. If timber be converted without regard to this result of dryness, the stuff will not only split, but will be so affected by changes of weather as to twist. If the cuts be made in lines converging, or even tending to the centre, the stuff may shrink in width but will neither split nor warp. Although oak is formed like other exogenous trees by a succession of layers, these are united and solidified in this particular wood by the medullary rays which form a sort of natural dowel.

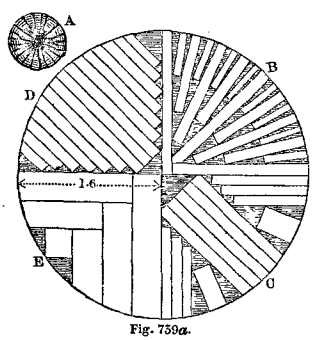

Fig. 739*a*.

2125*b*. The best method of converting oak for the use of the joiner is shown at B, *fig.* 739*a*., in which there is no waste, as the triangular portions form feather-edged laths for tiling and other purposes. The next best method is that at C; that at D is inferior; but the most economical method, where thickness is required, as for planks or for moulded work, is that marked E. The resemblance to a watered silk, which is sometimes called the feather, or flower, or curl, or pattern, of wainscot, is due to the medullary rays, which show most when the saw follows the chink-grain as in B; in C and D the silky appearance does not exist, as most of the rays are cut across; very slight examination will show which course has been followed, especially in the case of the quarter-grain stuff produced by the method E. It is probable that the cross-cuts will follow the line of a layer, called the felt-grain, in the plan marked B, which is that adopted in Holland on timber furnished in great part from Champagne (whence, simply, the superiority of Dutch wainscot), and in all cases of split oak for lathing and for park paling. (Viollet-le-Duc).

2125*c*. The wood principally used for joinery is of three sorts, pine, and white and yellow deal; the two first for panelling, and the last for framing. Of late years much American wood has been used, both for panels and frames. It works easily, is soft, free from knots, but more liable to warp than white deal. But joinery is not of course limited to the use of a particular sort of wood. When the exporter cuts a log, the first thing done is to get one good deal or more for the London market; the residue is then converted to supply other markets. Many deals 3 inches thick are sent to France, perhaps as large a proportion as those of 2 inch and $1\frac{1}{4}$ inch, but they are not of so good a description as those sent to London. France is the great mart for all deals that will not suit the London

market. The following are the modes which have been and are at present practised to obtain deals for both markets. In 739*b*. (the mode practised until the French market improved), are obtained an English deal, A, 9 in. by 3 in, and two battens, B, 7 in. by 2½ in., making 62 feet superficial. In 739*c*., the old mode of cutting, gave two English deals, C, 9 in. by 2½ in., and two English battens, D, 7 in. by 2½ in., making 80 feet superficial. In 739*d*., the present mode of cutting, gives two English deals, E, 9 in. by 3 in., and two French deals, F, 9 in. by 1¼ in., making 76½ feet superficial. This communication has been obligingly furnished by Mr. T. A. Britton, as obtained at the Docks.

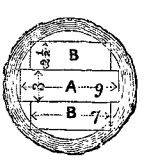

Fig. 739*b*.

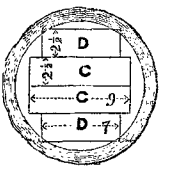

Fig. 739*c*.

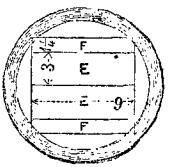

Fig. 739*d*.

2125*d*. *Glue* is a material extensively used in joinery; see GLOSSARY, and Addendum.

MOULDINGS.

2126. When the edge of a piece of wood is reduced to a cylindrical form, it is said to be *rounded*, which is the simplest kind of moulded work. (*Fig.* 740.) When a portion of the arris is made semicylindrical, so that the surface of the cylindrical part is flush both with the face and the edge of the wood, with a groove or sinking made in the face only, the cylindrical part is called a bead, and the sinking a quirk; the whole combination (*fig.* 741.) being called a *quirked bead*.

2127. If a quirk is also formed on the other or returning face, so as to make the rounded part at the angle three fourths of a cylinder, the moulding (see *fig.* 742.) is called a *bead and double quirk*.

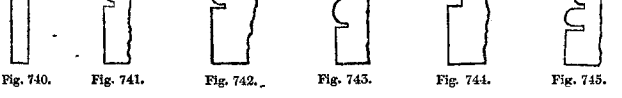

Fig. 740. Fig. 741. Fig. 742. Fig. 743. Fig. 744. Fig. 745.

2128. If two semicylindrical mouldings both rise from a plane parallel to the face, and one comes close to the edge of the piece and the other has a quirk on the further side, and its surface flush with the face of the wood, as in *fig.* 743., the combination is called a *double bead* or *double bead and quirk*, wherein the bead next to the edge of the stuff is much smaller than the other.

2129. Mouldings are usually separated from one another, and often terminated by two narrow planes at right angles (*fig.* 744.) to each other: these are called *fillets*, and show two sides of a rectangular prism. The different pieces of the combination of mouldings are called *members*. A semicylindrical moulding, rising from a plane parallel to the face, and terminated on the edge by a fillet (*fig.* 745.), is called a *torus*. In the figure there are two semicylindrical mouldings, whence that is called a *double torus*. The reader must observe that the distinction between torus mouldings and beads in joinery is, that the outer edge of the former always terminates with a fillet, whether the torus be single or double; whereas a bead never has a fillet on the outer edge. A repetition of equal semicylindrical mouldings, springing from a plane or cylindrical surface, is called *reeds*. In joinery, the ⌒, *cima recta*, and ⌓, *cima reversa*, are called respectively the *ogee* and *ogee reverse*. The ovolo ⌓, so named from its egg-like form, and the *quarter round*, the fourth part of a cylindrical surface, are the remaining of the principal mouldings used in joinery. When the margin of any framing terminates on the edges next to the panel, with one or more mouldings, which both advance before and retire from the face of the framing to the panelling, the mouldings thus introduced are called *bolection mouldings*. (See *fig.* 759.) Mediæval mouldings will be treated in the chapter PRACTICE OF ARCHITECTURE.

DOORS.

2130. We shall now more particularly address ourselves to the subject of doors and their mouldings. The most inferior sort of door used in building is the *common ledged door*, in which five or six or seven vertical boards are held together usually by three horizontal pieces called ledges, to which the vertical ones are nailed. Sometimes there is an outer framing, consisting of the top rail and the two outside stiles, but still having ledges as

before; these are called *framed and ledged doors*. A door, properly made, is formed by framing and fitting pieces of stuff together of the same thickness; those which are horizontal (*fig.* 746.) AAAA being called *rails*, and those which are vertical BBBB being called *stiles*. These form a skeleton into which *panels*, usually of a less thickness, are fitted. And this, indeed, is the general practice in all systems of framed joinery. In doors, the upper rails are called *top rails*; the next in descending, *frieze rails*; the next, which are usually wider than the two first, are called the *lock* or *middle rails*; and the lowest, from their situation, are called *bottom rails*. The stiles on the flanks are called *outside stiles*, and those in the middle are called *middle stiles*. The panels are also named from their situations on the door; thus CC, being the uppermost, are called *frieze panels*; the next DD are called *middle panels*, and EE *bottom panels*. The rails and stiles are wedged together, being previously morticed and tenoned into each other. The student should, however, to obtain a clear comprehension of the method adopted, see a door put together at the bench. The varieties and forms of doors are dependent upon the will of the architect, from whom the design of the whole emanates; it will be, therefore, here sufficient to mention the three sorts, viz. the *common door*, just described; the *jib door*, which is made with the same finishings and appearance as the room in which it is placed, so as not to have the appearance of a door; and, lastly, *folding doors*, which open from the centre of the doorway, and are used for making a wider communication between two apartments than a common door will permit, or, in other words, to lay two rooms into one.

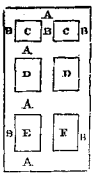

Fig. 746

2131. Though the panelling of framed work is generally sunk within the face of the framing, it is for outside work sometimes made flush. In the best flush work, the panels are surrounded with a bead formed on the edge of the framing, and the work is called *bead and flush*. In the commoner kind of flush framing, the bead is run only on the two edges of the panel in the direction of the fibres, and is called *bead and butt*.

2132. The different denominations of framed doors, according to their mouldings and panels and framed work in general, are as follows. The figures by which they are represented are sections of doors through one of the stiles, wherein only a small part of the panel is shown, or they may be equally considered as vertical sections, through the top rail and part of the panel below it.

2133. *Fig.* 747. represents the commonest door. It is without mouldings, and the panel is a straight surface on both sides. It is technically described, first mentioning the number

Fig. 747.

Fig. 748.

Fig. 749.

Fig. 750.

Fig. 751.

of panels intended in it, as a *door square and flat panel on both sides*. We shall not, in the following, repeat the observation as to the number of panels, that being always supposed as mentioned, but it will be found carried out under Specifications.

2134. *Fig.* 748. represents the rail and panel of a door, with a quirked ovolo and a fillet on one side, but having no mouldings on the other. The panel flat on both sides, it is described as a *door with quirked ovolo, fillet and flat with square back*.

2135. *Fig.* 749. only differs from the last in having a bead instead of a fillet, and is described as *quirked ovolo, bead and flat panel with square back*.

2136. *Fig.* 750., with an additional fillet on the framing, is described as *quirked ovolo, bead fillet and flat panel with square back*. The back, in the foregoing and following cases, is described as square, because of its having no mouldings on the framing, and of the panel being a straight surface on one side of the door.

2137. In *fig.* 751. the framing is formed with a quirked ogee, and a quirked bead on one side and square on the other, the surface of the panel being straight on both sides, and the door is described as *quirked ogee, quirked bead and flat panel with square back*.

2138. *Fig.* 752. only differs from the last in the bead being raised above the lower part of the ogee and a fillet. It is described as *quirked ogee, cocked bead and flat panel with square back*.

2139. *Fig.* 753. is described as a door with *cove, cocked bead, flat panel and square back.*

Fig. 752.

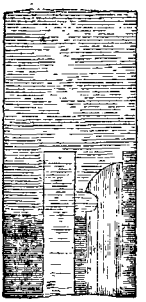

Fig. 753.

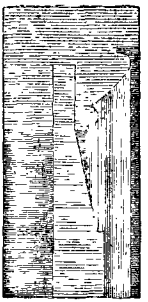

Fig. 754.

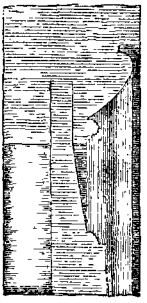

Fig. 755.

2140. *Fig.* 754. is a combination, by which much strength is imparted to the door, and it is therefore much used for external doors. It is, however, often in the interior of houses, and is described, *quirked ovolo, bead fillet and raised panel on front and square back.* It is from the raising of the panel that the additional strength is acquired.

2141. *Fig.* 755. resembles the last in general appearance, the difference being in the ovolo on the raised panel. It is described, *quirked ovolo, bead and raised panel, with ovolo on the raised panel and square back.* When an external door has raised panels, they are always placed towards the exterior.

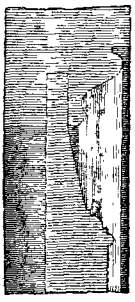

Fig. 756

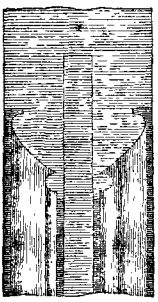

Fig. 757.

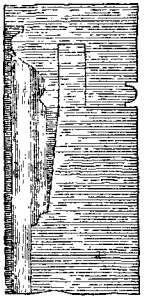

Fig. 758.

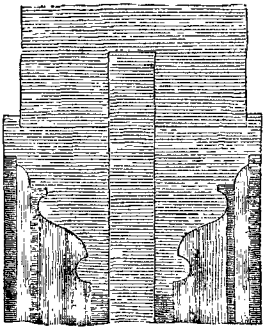

Fig. 759.

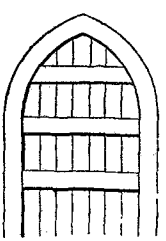
2142. In *fig.* 756. there are more mouldings than in the last on the raised panel. It is described, *quirked ogee, raised panel with ovolo and fillet on the rising and astragal on the flat of panel in front and square back.*

2143. *Fig.* 757. is described, *quirked ovolo, bead fillet and flat panel on both sides.* This description of doors is used where a handsome appearance is to be equally preserved on both sides of the door, as between rooms, or between halls or principal passages and rooms.

2144. *Fig.* 758. is a combination used, as all bead butt and bead flush work is, where strength is required. The form here given is described, *bead and flush front and quirked ogee, raised panel with ovolo on the rising, grooved on flat panel on back.*

2145. The series of mouldings are, as we have before mentioned, called *bolection* mouldings (*fig.* 759.), and are laid in after the door is framed square and put together. They project beyond the framing on each side. When bradded on through the sides of the quirks, the heads of the brads will be entirely concealed; but it is to be observed that, in driving the brads, they must not be directed towards the panels, but into the solid of the framing. The form of these bolection mouldings is of course varied according to the pleasure of the architect.



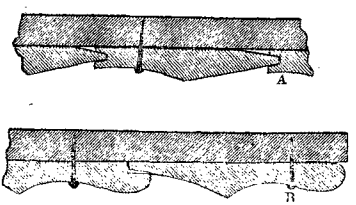


Fig. 759*a*.

2145*a*. *Mediæval Doors*, of a simple sort, were formed of planks placed upright, grooved or feather-tongued at the edges, and generally secured

together by plain band-hinges, or more or less ornamented, or with scroll work. These planks are further nailed to a skeleton framing. *Fig. 759a.* gives a sketch of the back of the door at Bidborough Church, Kent, with its planking at A; and B is a section of the same at Staplehurst Church, Kent; the place for the nails is only indicated. These examples were supplied to the *Dictionary of Architecture* by Professor Lewis. Larger doors were made up of frames and rails, strutted or braced, on the same principle as the modern ledged doors and coach-house gates. Viollet le Duc's *Dictionnaire* has many examples of this mode of framing, all the timbers being stop-chamfered, and the planks bolted through the braces.

2145*b*. The head of a door enriched with panelling; the door, with the planks carved with panelling, running ornament, and niches with figures; an early English door, with two foliated band hinges; of the same period with three hinges; of the decorated period, the panelled and enriched headed door at Holbeach Church, Lincolnshire, of which the construction (a framing of square panels, AA) is shown in *fig. 759b.*, rising from a plain plank 14½ inches high; with other examples, are all given in Brandon, *Analysis*, etc. together with one of the perpendicular period, wherein the face has panelled planks, and square panel framing at back.

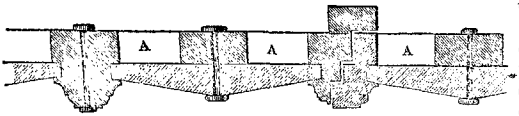

Fig. 759*b*.

2145*c*. The framework is sometimes placed externally and ornamented, as in *fig. 759c.*, from the west door of the Church of San Pietro; and *fig. 759d.*, from a door in a courtyard opposite that of Sta. Maria Antica, both at Verona. The sizes are 9½ inches and 12 inches respectively, from centre to centre of panels. These cuts are taken from the plates of the *Dictionary*. The very elaborate moulded and carved door from the Norman portion (12th century) of the Palazzo Reale, at Palermo, is given in the illustrations of the *Dictionary of Architecture*, from careful measurements by the late J. M. Lockyer. In the doors of cedar or deal, but covered with paint, at the chapels of St. Martin and St. Giles at Notre Dame le Puy (cir. 1043–53.), the subjects, inscriptions, and borders are all obtained simply by sinking the ground 3-16ths of an inch. Gates of the same description are said to exist in the churches of Chamalières and Lavoûte-Chilhac in the same district. The wood doors, having iron plates beaten up into a pattern secured with large brass nails, at Huesca Cathedral, date about 1400-1405, the era of the erection of the west entrance. (*Street.*)

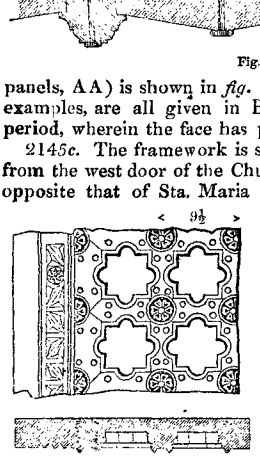

Fig. 759*c*.

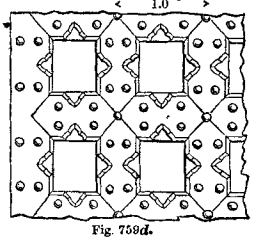

Fig. 759*d*.

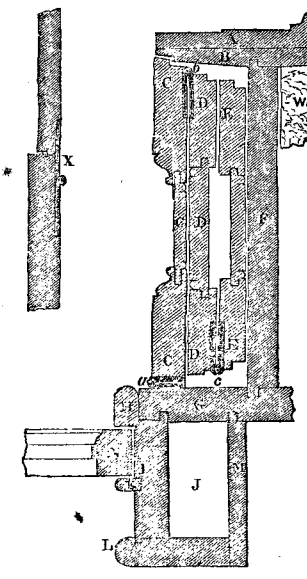

Fig. 760.

SHUTTERS.

2146. *Shutters*, which are the doors of window openings, are framed upon the same principles as doors themselves; but their backs are very often flush. In the better sort of buildings they are folded into recesses called *boxings*, whereof we shall give a figure below as an example of the ordinary method; but as the extent and different forms of windows vary, the ingenuity of the architect will be often required to contrive his shutters within a very small space. Into minutiæ we cannot enter in a work of this nature; however, in all their shapes, they are dependent on the leading principles given.

2147. *Fig. 760.* is a plan of the shutters, architrave, sash-frame, and part of the sash of common shutters. The cavity which forms the *boxing* into which the sashes fold is formed by the ground B (upon which the architrave A is nailed), the *back lining* F of the boxing, and the *inside lining* G of the sash-frame, whereof H is the *inside bead*. L is the *outside lining* of the sash-frame, M the *back lining* of it, and K the *parting bead*, so called from parting the upper and

lower sash. The vacant space J, between the pulley piece I and M, is a cavity which contains the weights for balancing the sashes; N shows the plan of one of them. The shutters, when stretched out in their different folds, are supposed to cover one half of the window, another series being supposed to be placed on the other side of it. The *front shutter* CCC is hung by hinges at *a* to the inside lining G of the sash-frame. The inner shutters DDD and EE are called the *back flaps*, the former of which is hinged on to the front shutter at *b*, and the latter is hinged on to DDD at *c*. It will be immediately seen that these three will thus altogether turn upon the hinges at *a*, and cover, in one straight line, from both sides, the whole of the light of the window. When the boxes are scanty, the hinge, called a *back flap hinge*, may be placed as shown in X attached to the figure.

2148. In ordinary cases, this example will sufficiently exhibit the method to be adopted. When it is not applicable, the architect must apply himself to the work *pro re natâ*, in which, with very little attention, he will not find insurmountable difficulty.

2148*a*. The *boxings* of a window are further described in the GLOSSARY and Addendum. Besides the *lifting shutters* commonly used in houses of a lower rate, which in their construction is simply a repetition of the sash-frame, we must notice briefly the many *revolving shutters* for inside and outside purposes, whether of iron, steel, or wood, laths. The latter were first made at Ipswich, some twenty years since, and were wound up and down by a winch and upright rod working a toothed wheel. They were soon afterwards made of iron, also worked by machinery. Within the last few years, their great convenience has led to many improvements, and the greater use of wood; instead of machinery, counterbalance weights were introduced. Later, they were "constructed of laths of wood rebated together, having numerous mortices, through which pass a series of tempered steel bands, causing the shutter to be *self-coiling*." Iron laths were also used. Lately, they "are made of steel, in one sheet, without either chains, links or rivets, or pins; the steel being corrugated transversely gives them the appearance of laths, and enables them to be coiled into a small space." We avail ourselves of some illustrations issued by Clark and Co., showing the adaptability of this shutter to various places, as windows, shops, doors, fireplaces, &c. *Fig.* 760*a*. shows the head and foot of an ordinary house window. At A, it is fitted with the shutter inside, and to pull down. At B, it is fitted also inside, and to lift up, the coil being placed in a boxing forming a step on the floor. When the position of the joists admit of so doing, the coil may be placed *in* the flooring, as at C; and occasionally it may be more convenient to place it even *under* the ceiling, at D. *Fig.* 760*b*. is the plan of a window frame, showing the groove, *a*, for the shutter, which is 1 inch deep by $\frac{7}{8}$ths wide.

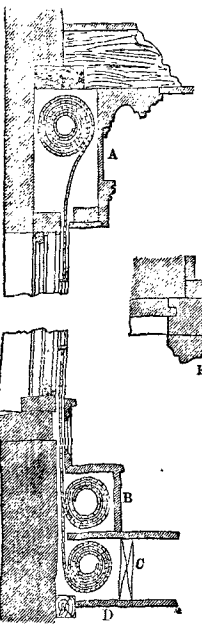

Fig. 760*a*.

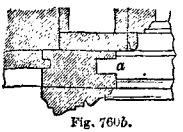

Fig. 760*b*.

2148*b*. A great improvement in securing the common shop shutters without a shutter-bar is one of the early inventions introduced by Jennings; these *shutter shoes* are so much advertised with illustrations that further notice of them herein is needless.

HINGEING.

2149. A very essential consideration in the neatness and beauty of joiners' work, is the formation of the joints on which are placed the hinges of doors and shutters. They ought to be so continued as to preserve the uniformity of the door or shutter on both sides, and as much as possible to be close enough to exclude a rush of air between the edges of the bodies to be hinged together, which, in this cold climate, is essential. In these joints, both angles of one of the bodies is usually beaded, to conceal the open space, which would otherwise be seen; and for preserving the appearance of the work, the hinges are made of such a curvature towards the eye, as to seem, when painted, a part of the bead itself on that side where the knuckle is placed, so that when hung the whole may appear to be one bead.

2150. The section of a door style, and part of the *hanging style* at the joint, are represented in A and B (*fig.* 761.), wherein the centre of the bead on each side is in the line of the straight part of the joint from the opposite side. In this figure, C is the centre of the bead, AG part of the joint in a line with its edge. Joining AC, draw AB perpendicular thereto. The other part BH is perpendicular to EF, which

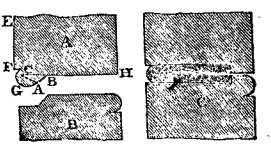

Fig. 761.

is the face of the door or hanging style. This is a joint suitable for many purposes, and may be made with common hinges. If crooked, it will assist in excluding the current of air, a point of no mean importance.

2151. In *fig.* 762. A and B exhibit a plane joint, beaded similarly on both sides. In this case, the plane of the joint is a tangent to the cylindrical surfaces of the two beads; and as the margin on each side is alike, no check to the rush of cold air is afforded. The hinge, moreover, is such that it cannot be made in the usual manner, but must be formed as at C.

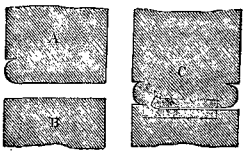

Fig. 762.

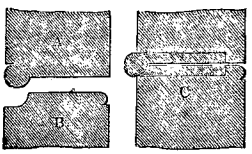

Fig. 763.

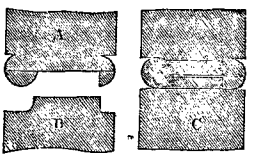

Fig. 764.

2152. *Fig.* 763. A and B represent a hinging wherein the plane of the joint from one side is directed to the axis of the bead on the other. The principle in it is the same as that in *fig.* 761., and it may therefore be hinged with common hinges, as shown in C, in which the two parts are conjoined. The methods shown in this and *fig.* 761. are useful in cases wherein a part of the margin is concealed on one side of the door.

2153. *Fig.* 764. A and B exhibit the beads of similar size on each side, and exactly opposite to each other, the joint being broken by indenting a part terminated by a plane directed to the axis of the two opposite beads. The hinges are required merely of the common form, the arrangement is strong, and the apartment rendered comfortable by their use. In C the parts are shown as hinged together.

2154. In *fig.* 765. the beads are on both sides, but not on the same piece, as in the last figure. The appearance is uniform, but the bead, which projects the whole of its thickness, is weakened. The junction is seen in the representation at C.

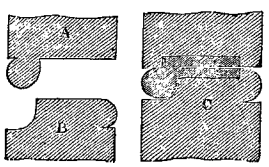

Fig. 765.

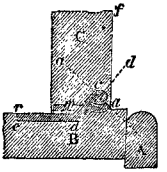

Fig. 766.

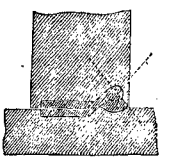

Fig. 767.

2155. *Fig.* 766. is a method that has been adopted for concealing the hinges of shutters. A is the inner bead of the sash-frame, B the inside lining, C the style of the shutter. For the form of the joint, let *af* be the face of the shutter, perpendicular to *ar* the face of the inside lining. Let the angle *f a r* be bisected by the straight line *aa*, and in the centre take *c*. Draw *dd* perpendicular to *aa*, cutting it in *c*, which is the centre of the hinge. From *c*, as a centre, describe the arc *am*, which must be hollowed out from the inside lining of the sash through the height of the shutter. In order to make room for the opening and shutting of the hinge, the internal right angle of the shutter must be cut out of its edge to the breadth of the hinges. The *toils* of the hinge are here for the purpose of strengthening them, represented of different lengths.

2156. In *fig.* 767. the hinges, which are for a door, are concealed, as the door allows it in the thickness of the wood, the ends of the hinges being of equal lengths.

2157. *Fig.* 768. shows the common method of hingeing shutters, a mode wherein the whole thickness of the hinge is let into the thickness of the shutter, the inside lining being assumed as too thin to afford sufficient hold for the screws employed to fasten them.

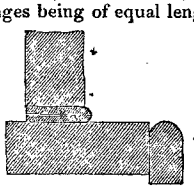

Fig. 768.

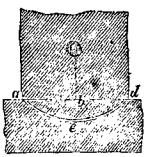

Fig. 769.

2158. *Fig.* 769. exhibits the hanging of a door with the centres concealed. Let *ad* be the side of the jamb in contact with the edge of the door; bisect it in *b*, and draw *bc* perpendicular to *ad*, make *bc* equal to *ba* or *bd*, and join *ac* and *cd*; from *c*, as a centre, describe the arc *aed*, which will show the portion to be hollowed out of the jamb. The centres are fixed to the upper and under parts of the door, and the former is to be so constructed as to allow its being taken out of the socket to unhang the door when required.

2159. Shutters are usually hung in the way represented in *fig.* 770., wherein the centre

of the knuckle of the hinge is exactly opposite to the perpendicular part of the rebate. The dotted lines exhibit the flap when folded back.

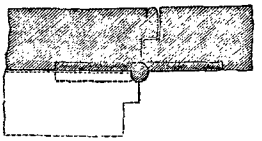

Fig. 770.

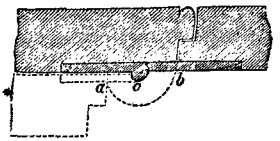

Fig 771.

2160. When the axis of the knuckle cannot be disposed so as to fall opposite to the joint, the hinge is to be placed as shown in *fig.* 771. Thus, *ab* being the distance of the edge of the flap from that of the shutter, bisect it in *c*, which will be the point opposite whereto the centre of the hinge is to be placed. This arrangement is necessary, both when the shutters are not square at the ends, and when the boxing is restricted in space; the principle being to place the centre of the knuckle of the hinge at half the distance of the edge of the flap from the rebate on the edge of the shutter. In *fig.* 772. the two parts are shown hinged together.

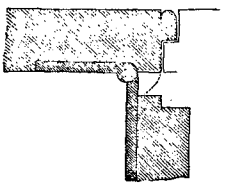

Fig. 772.

2161. When a door has attached to it any projection, and, when open, it is requisite to bring it parallel to its place when shut, the knuckle of the hinge (*fig.* 773.) must project at least as far as the projection in question. An inspection of the diagram, wherein the dotted lines show the situation of the door when folded back, will sufficiently convey the mode of conducting this expedient.

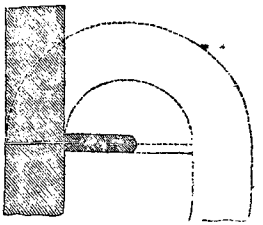

Fig. 773.

2162. *Fig.* 774. is the representation of what is called a *rule joint*, which is used when the piece to be hung is not required to open to more than a right angle. In this case, the centre of the hinge is necessarily in the centre of the arc. In *fig.* 775. the expedient shows the method turned to a right angle.

2163. The various methods of hingeing to suit every possible case would occupy a very large space, were we to enter into them; and even after exhausting all the cases that we may have imagined, others would arise to which no example given might be applicable; we therefore leave this portion of the subject of joinery, under an impression that the principles have been sufficiently developed to enable the student to pursue from them the application to any case that he may be called upon to put in practice.

Fig. 774.

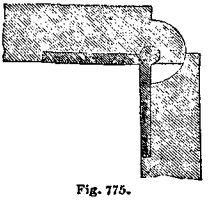

Fig. 775.

SASH-FRAMES AND SASHES.

2164. In *fig.* 760. the connection between the shutters and sash-frame has been fully explained; we may now, therefore, proceed to the detail of a common sash-frame with its sashes, supposing them to be hung so as to be balanced by weights, suspended by sash-lines running over pulleys, capable of balancing those of the sashes themselves. On the case of *French sashes*, which open like doors, we do not think it necessary to dilate. *They* are, in fact, nothing more than glazed doors; and the principal object for attainment in their construction, is to prevent the rain from penetrating into the apartments they serve, as well where they meet in the middle as at their sills, which is a subject requiring much care and attention.

2165. In *fig.* 776. is shown the construction of a sash-frame, and the method of putting together the several parts, wherein R is the elevation of the frame, of which ABCD is the outer edge. The thinner lines at EF, GH, FG, are grooves whose distances from the edges of the sash-frame LM and KI are equal to the depth of the boxing, together with three-eighths of an inch more that is allowed for margin between the face of the shutter, when, in the boxing, and the edges ML and KI of the sash-frame next to the bead. S is a horizontal section of the sides, whereon is shown also the plan of the sill. T is a vertical section of the sill and top, in which is shown the elevation of the pully style *m* and *n*, and the pullies let into the pully piece. U is the horizontal section of the sides, showing also a plan of the head of the sash-frame. V the elevation of the outer side of the sash-frame; the outside lining being removed for the purpose of showing the work within the sash-frame. In this *fg* is the *parting strip* fastened by a pin; *ed* one of the weights connected to the sash by means of a line going over the pulley *c*, the other end being fixed to the edge of the sash.

The weight *de* is made equal to one half the weight of the sash. W is the head of the sash-frame before put together, and X shows the edge of W. Y is the edge of the bottom, exhibiting the manner of putting the styles in it, and Z is the plan of Y. *Fig.* 777., Nos. 1. and 2., are sections of the sills of sash-frames, with sections of the under rail of the sash, showing the best method of constructing them, in order to prevent rain from driving under the sash-rail. In each of these, A is the section of the bottom rail, B a section of the bead tongued into the sill, C a section of the sill. *Fig.* 778. exhibits sections of the meeting rails of the upper and lower sashes, with side elevations of the upright bars; C is the rebate for the glass, D a square, E and F an astragal and hollow moulding, G a fillet. The smaller letters mark the same parts of the under sash. *Fig.* 779. is the section of an upright bar with the plans of two horizontal bars, showing the *franking* or manner in which they are put together to keep the upright bars as strong as possible. The thickness of the tenon in

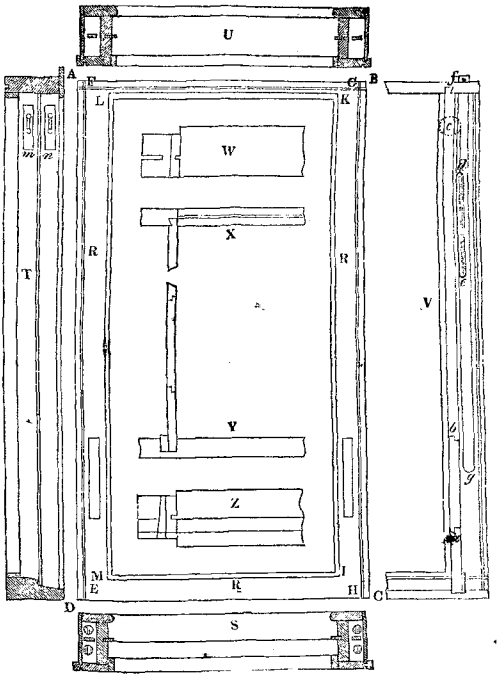

Fig. 776.

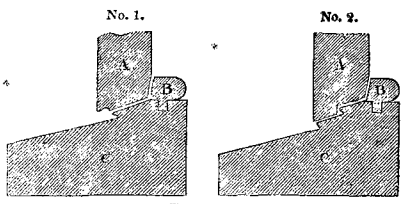

Fig. 777.

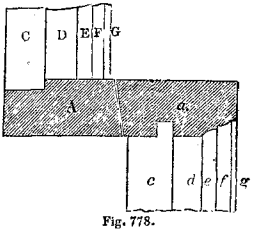

Fig. 778.

general is about one sixteenth of an inch to the edge of the hollow of the astragal, and close to the rebate on the other side. *hh* is a dowel to keep the horizontal bars still firmer together. In this diagram the letters refer to the same parts as in the preceding figure; and it is also to be observed, that no rebate is made for the glass on the inside meeting rail, a groove being made to answer that purpose. *Fig.* 780. exhibits four sections of sash bars. But their forms, as in the case of mouldings, generally depends on the taste of the architect.

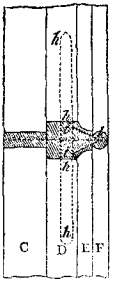

Fig. 779.

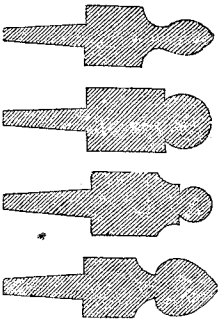

Fig. 780.

2165*a*. Several patents have been taken out, of late years, for hanging sashes so that they may be removed from the frames for cleaning or repairing without taking down the inside beads, an operation which always results in at least damaging them in a few years. They are not always satisfactory. Gurman's *sash pocket and fittings*, and Gribbons' *sash mountings*, were introduced about 1858. Other inventions have been made for hanging them so that the upper and lower sashes shall open with the same action. William M'Adam's "Imperishable material applied to sash and other pulleys, economical sash weights, and improved methods of hanging windows," comprises

a material for pulleys of vitrified stoneware, proof against the action of the weather. For window weights he substitutes a cheap material manufactured out of various kinds of refuse; and suggests an improvement in the mode of hanging windows whereby one weight can be made to answer the same purposes as two applied in the usual way. For sash lines see the GLOSSARY, Addendum.

2165*b*. The *French casement window*, or *sash door* as it is called when it opens down to the ground, is a feature commonly introduced even into English town houses. Its most ordinary form for small apertures is that of two leaves opening inwards or outwards, meeting in the centre of the opening; one leaf being secured to the frame by a bolt at top and bottom, and the other, when closed, is fastened to the first by a handle, fixed on the second leaf, and turning over a staple fixed on the first. When the casement is high, this second leaf may require a bolt also at top and bottom to prevent the wind bending it (when inwards), and so admitting cold air and wet. When placed towards an exposed quarter,

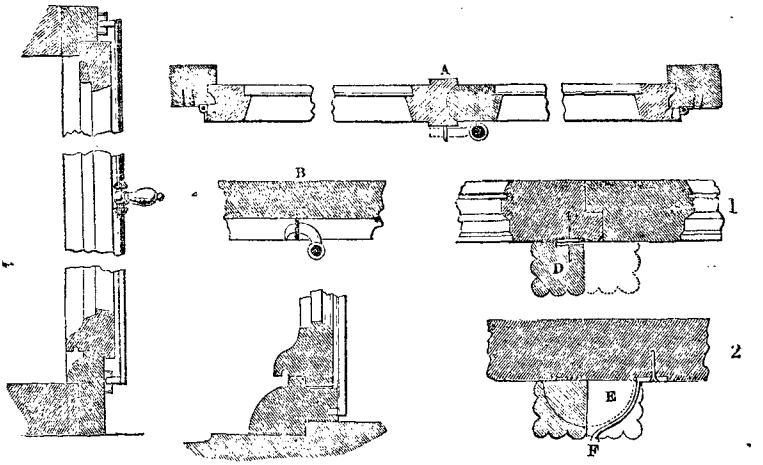

Fig. 780*a*. Fig. 780*b*. Fig. 780*c*.

and subject to driving rains, it becomes necessary to take extra precautions to prevent the wet being blown through the joints at the bottom and the sides. To effect this object, the stiles, rails, and frames are beaded and sunk in various manners; some are shown in *figs.* 780*a*. and 780*b*., sills and bottom rails. For the latter, a *water bar* is now much used.

2165*c*. The next improvement is perhaps that of affixing to the leaf which is first opened an upright bar, which turns, and on being closed, fits against the other leaf, and by a hook at top and bottom effectually fastens both leaves. A similar method is shown in *fig.* 780*c*., adopted at Pisa, as given in the *Papers* of the Royal Engineers, x. 187. The upright square reeded bar D, is moved to or from the sash, as the window is required to be opened or shut; the top and bottom of the bar being rounded, as shown at E, so as to slide into two segmental plates F, secured

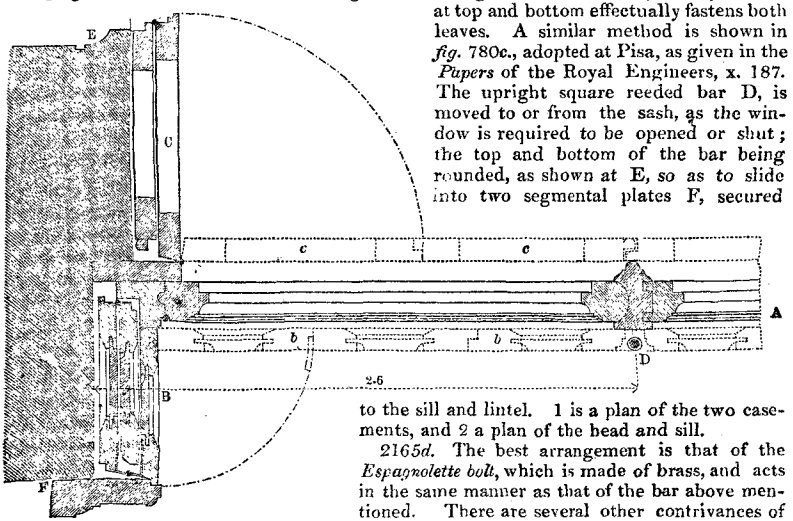

Fig. 780*a*.

to the sill and lintel. 1 is a plan of the two casements, and 2 a plan of the head and sill.

2165*d*. The best arrangement is that of the *Espagnolette bolt*, which is made of brass, and acts in the same manner as that of the bar above mentioned. There are several other contrivances of a similar kind to effect the object, but the above

are those in most general use. There is also a late invention for forming the bolt into a plate, and setting it in a groove in the *edge* of the meeting stile, a corresponding groove being formed in the other stile to receive its half of the plate when moved forward by the handle in closing the casement. This, at the same time, forms a weather bar. (See *par.* 2259.)

2165*e*. The *fig.* 780*a*. is a section of an ordinary arrangement in France for a casement. A is the plan, taken across the middle of the height, near the handle; and B the plan of the hooks at top and bottom of the rod, working into a staple fixed in the head and in the sill, with the movement of the rod by its handle. The round and hollow joint in the middle of the casement necessitates the two leaves being closed together and pressed into the frame when shutting the leaves, thus securing all the joints from admitting air or water.

2165*f*. *Fig.* 780*d*. is a plan of the elaborate but usual French casement, as lately put up to the stone-fronted houses in the Rue de la Victoire, at Paris. It is given by Daly, in the *Revue Generale de l'Architecture* of 1858. A shows the casements when shut; B the shutters closed in the boxings; and *b b* the shutters when opened out. C the *persiennes* or outside blinds shut against the stone reveals; the ordinary mode is for them to shut on the face of the wall, which spoils the architecture of the façade; *c c* the same when closed; D the espagnolette bolt; E the outside architrave; and F the inside architrave.

GROUNDS.

2166. *Grounds* are formed of pieces of wood forming skeleton frames, and attached to walls, around windows, doors, or other openings, for the facility of fixing architraves or other mouldings upon them. For doorways the front and back grounds were connected by a third, specified as *dovetailed backing*. They are disused in common work, the grounds being the wrought woodwork carrying the mouldings, forming a single or double faced architrave, and having the jamb space filled by a single or a double rebated and beaded jamb lining. The grounds served as screeds for the plastering, for which purpose the edge was chamfered, rebated, or grooved. Grounds or *narrow grounds* were those to which the bases and surbases of rooms were fastened; slips of wood now receive the skirtings of rooms. All these appliances were secured to wood, bricks, which themselves have given way to plugs or wedges. In all cases the grounds ought to be fixed vertical on the face and edge, and the workman should take especial care to fix them firm and solid in every part; for, without accuracy and firmness, the inside work cannot be well finished, as it is to be recollected that in plastered rooms the plaster is worked to them.

2167. In fixing window grounds, the sash-frame must be first carefully placed so as to stand perfectly vertical; and then the face of the ground must stand quite parallel to the face of the sash-frame, and project about three quarters of an inch from the face of the naked brickwork, so as to leave a sufficient space for the thickness of the plaster. The edge of the ground should be in the same plane with the edge of the sash-frame, or, as the workmen term it, "out of winding." The edge of the architrave, when finished, in ordinary cases, will stand about three-eighths of an inch within the inner edge of the sash-frame, so that a perpendicular line down to the middle of the grounds would stand exactly opposite to a perpendicular line down to the middle of the sash-frame.

FLOORS OR FLOOR BOARDS.

2168. In the laying of floors, the first care to be taken is that they be perfectly level, which, owing to the nature of the materials whereof they are constructed, is a difficult task. The chief sorts of floors may be divided into those which are *folded*, that is, when the boards are laid in divisions, whose side vertical joints are not continuous, but in bays of three, four, five, or more boards in a bay or fold; and those which are *straight joint*, in which the side joints of the boards are continuous throughout their direction.

As soon as the windows are fixed, the floors of a building may be laid. The boards are to be placed on their best face, and put to season till the sap is quite exhausted, when they may be planed smooth, and their edges shot and squared. The opposite edges are brought to a breadth by drawing a line on the face parallel to the other edge with a flooring guage, after which the common guage is used to bring them to a thickness, and they are rebated down on the back to the lines drawn by the guage.

2169. The next operation is, to try the joints, which, if not level, must be brought so, either by *furring up* if they be hollow, or by adzing down if they are convex, the former being more generally the case.

2170. The boards used for flooring are battens, or deals of greater breadth, whose qualities are of three sorts. The best is that free from knots, shakes, sapwood, or cross-grained stuff, selected so as to match well with one another. The second best is free of shakes and sapwood, and in it only small sound knots are permitted. The third, or most common sort, are such as are left after taking away the best and second best.

2171. The joints of flooring-boards are either quite square, ploughed and tongued, rebated, or dowelled; and in fixing them they are nailed on one or both edges, when the joints are plain and square without dowels. When they are dowelled, they may be nailed on one or both sides; but in the best dowelled work the outer edge only is nailed, by driving the brad through the edge of the board obliquely, without piercing its surface, which, when the work is cleaned off, appears without blemish.

2172. In laying the floor-boards, they are sometimes laid one after the other, or one is first laid, then the fourth, at an interval of something less than the united breadth of the second and third together. The two intermediate boards are then laid in their places with one edge on the edge of the first board and the other upon that of the fourth board, the two middle edges resting against each other, rising to a ridge at the joint. In order to force these boards into their places, two or three workmen jump upon the ridge till they have brought the under sides of the boards close to the joints; they are then fixed in their places with brads. This method is that first mentioned under this head, and in it the boards are said to be folded. We have here mentioned only two boards, but four boards are most commonly folded at a time, and the mode is always resorted to when a suspicion exists that the boards are not sufficiently seasoned, or they are known not to be so. The headings of these folds are either square, splayed, or ploughed and tongued. If a heading occurs in the length of the floor, it should be invariably made to fall over a joist, and one heading should not meet another.

2173. In dowelled floors, the dowels should be placed over the middle of the interjoist rather than over the joists, so that the edge of one board may be prevented from passing that of the other. When the boards are only bradded upon one edge, the brads are concealed by driving them in a slanting direction through the outer edge of every successive board, without piercing the upper surface. In adzing the under sides of floor-boards over each joist, great care should be taken to chip away the stuff straight, and also to avoid taking away more of the stuff than is necessary, in which case the soundness of the floor will not be compromised.

2173*a*. The practice of joining the edges of *boards* by means of rebates, or of tongued grooves, does not appear to have existed before the 15th century. Previously to that period, the use of ledges dovetailed to the whole or part of their depth into chases, of dovetailed wooden cramps, or of wood or iron pins or dowels, was general. In the cathedral at Messina the boarding under the tiling is in two thicknesses that cross each other; and, in the cradle roofs, it was usual to groove and tongue the wainscoting, and also to cover those joints with moulded fillets, as shown in the examples in *fig.* 780*e*. The thickness of this wainscoting, which was oak split, not sawn, was only three-eighths of an inch (barely more or less), and it was frequently put together in the manner shown in *fig.* 780*f*.

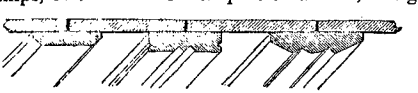

Fig. 780*e*.

Fig. 780*f*.

2173*b*. *Parquetry*, &c. Floors of principal rooms of the better class of houses are now being finished with parquetry. It is composed of different pieces of some four or five coloured and hard woods, arranged in regular geometrical figures, for the whole of a room, corridor, or gallery; or applied as borders round carpets, to treads and risers of stairs and landings; and even as dadoes, panellings, friezes, &c. Parquetry is kept clean by sweeping and periodical waxing. It is made *solid*, one inch thick, grooved, tongued, and keyed at the back and corners. When the woods are applied only as a veneer, they are liable to warp and separate by heat. "Wood tapestry (Howard's patent) for covering walls, ceilings, and other surfaces with real wood at a less cost than painting and graining," is a late invention. "Ornamental pyrographic woodwork," for panels and in cabinet work, being a process for burning-in ornament upon wood, is now in operation.

2173*c*. *Marquetry*, or the inlaying of coloured woods, became very general at the latter end of the 16th century. Oak was inlaid with ebony ornaments in the panels and stiles of wainscoting; and the framing of doors, windows, and shutters, was sometimes made of dark coloured woods, the panels being of light colours, inlaid with ornaments, profiles of heads, &c. This process is applied greatly to furniture, where it is imitated by paint. A new method has been introduced, of applying a printed pattern to the prepared wood, as in the Tunbridge ware, and then varnishing it as usual.

FRAMING.

2174. In *fig.* 781. are shown several methods for framing angles in dadoes, skirtings, troughs, and other objects, whereof A exhibits the method of mitring a dado on exterior angles in an apartment. In fixing this together, brads may be driven from each side. B is a method of framing used for troughs or other rectangular wooden vessels. C is a method of putting a dado or skirting together at any interior angle of a room. This mode

is also employed for water-trunks, or troughs. In D is shown the manner of fixing and finishing two pieces of framing together, with a bead at their meeting, by which the joint is concealed. It is used only in common finishings. In those of a better sort the angle is kept entire, and only a three-eighth bead used at the joint. It is of great importance in all joiner's work to preserve the sharpness of the angles of the work, and many prefer to employ the method shown in F, without any bead at the joint. In this the joint is made as close as possible, and is well glued together. If additional strength be required, blockings may be glued in the interior angle, which will make it quite firm. The method, by a simple mitre at E, is not so good as at A, because it has no abutment.

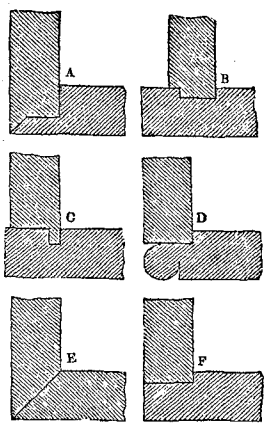

Fig. 781.

2175. When it is required to glue up large work, those edges which are to receive the glue should be well warmed at a fire, and then, while warm, and the glue as hot as possible, they should be united, inasmuch as glue never holds well when it is chilled or cold.

2175*a*. In studying mediæval *framing*, much attention should be given to the modes in which the junction of pieces was effected; there are two which are chiefly important. The first is a characteristic in the work of the carpenter as well as of the joiner, viz., the shoulder, either solid or applied (*figs.* 701*k*. and 701*l*.). In the first case, it is not economical of material, which was a great point of consideration; and therefore it is rarely seen except on short pieces, such as the posts of doorways: but as an applied means of strength it is almost as common in good work as a corbel in masonry. The second is the use of the mortice and tenon with trenails; and the extreme care which was given to this part of the work is scarcely to be expected in these days of speed and cheapness. It may be predicted that no truly mediæval work will now be ever reproduced except in the fancy-work of the cabinet-maker and the smith.

2175*b*. Another peculiarity is the use of stops to all chamfers and mouldings at points of junction of framing: it is not until the last phase of pointed art, that the stop of the moulding of a stile is worked in the rail, or that the corner of a panel is rounded: it is only in the dawn of the renaissance that the *four-panel quirk ogee front and square back* can be portion of a specification for a door; for a mitre-joint is eminently not a feature of mediæval joinery. The juxtaposition, even accidentally, of two stop-chamfered edges, suggests a means of enriching work, whether in open or close panels. The avoidance of work against the grain, and of large hollows, is also mentioned as a characteristic of joiner's work in pointed art; but this disappears in the course of the 15th century. The mediæval joiner, depending sometimes upon halving his work together, more frequently thought time less valuable than material, and did not repent a profusion of morticing and tenoning, to which he added the trouble of fastening with wooden trenails or iron pins. As large an amount of rebating and of grooving, however, was done in framing by the joiner as could be expected by those who were accustomed to the back-jointed and the grooved work of the mason.

2175*c*. Perhaps the most defective part of the joinery of the middle ages is that which consisted in planting one thickness upon another. The contrivances in glueing and dovetailing were not of themselves sufficient; and recourse was obliged to be had to nails. The absence of screws and nails, except where nail heads could be made decoration, is another characteristic of mediæval joinery. It was not until the beginning of the 14th century that the transition from planted work to panel work can be said to have appeared in any strength. At the end of that century, an architect might have specified a door as *nine-panelled, beaded three edges, chamfered bottom, and raised panel both sides*; but his beads would have been stuck in the solid, and not applied: during the whole of the 14th century planted work was commonly introduced, as in screens, closets, and shutters, where perhaps a sham buttress serves to conceal the wide joint made by the work in consequence of the inaccurate finish of the hingeing. A curious method, which must have been laborious before the introduction of the plane, of attaching the planted work, consisted in running in the ground a chase wide enough to take the whole breadth of the planted stuff, and then to run a couple of grooves in that chase; of course the back of the planted stuff had to be worked to match, with two tongues to enter the grooves.

2175*d*. The size of the materials was restricted. Three inch stuff for the thickness of rails and stiles, with a not much wider face; inch and a half stuff for mouldings to be planted; panels not more than eight inches wide, and three-quarters of an inch thick; may be quoted as usual dimensions for joiner's work. The observance of this restriction constitutes an essential characteristic of mediæval work.

STAIRS.

2176. *Stairs* and their *handrails* are among the most important objects of the joiner's skill. The choice of situation, sufficiency of light, and easy ascent, are matters for the exercise of the architect's best talent.

2177. There are some leading principles which are common to all staircases, of whatsoever materials they may be constructed. Thus it is a maxim that a broad step should be of less height than one which is narrower; and the reason is sufficiently obvious, because in striding, what a man loses in breadth he can more easily apply in raising himself by his feet. Now, as in common practice it is found that the convenient rise of a step 12 inches in width is $5\frac{1}{2}$ inches, it may be assumed as some guide for the regulation of other dimensions. Thus $12 \times 5\frac{1}{2} = 66$, which would be a constant numerator for the proportion. Suppose, for instance, a step 10 inches in breadth, then $\frac{66}{10} = 6\frac{3}{5}$ inches would be the height; and this agrees very nearly with the common practice. The breadth of steps in the commonest staircase may be taken at 10 inches at a medium. In the best staircases the breadth of the step should not be less than 12 inches, neither should it be more than 18 inches. (See 2814.)

2178. Having adjusted the proportions of the steps, our next consideration is to ascertain the number of risers which will be necessary to carry us from one floor to another. Suppose, for example, the height from the top of one floor to that of the next be 15 feet = 180 inches; here, if the steps are each of 6 inches rise, we have $\frac{180}{6} = 30$, which is the number of risers necessary to ascend from floor to floor. If the height divided by the rise of each step should not give an exact number of risers, it is better to add one rather than diminish the number. Thus, suppose the distance from floor to floor to be 13 feet 2 inches = 158 inches, then $\frac{158}{7} = 22\frac{4}{7}$. Here it would be better to take 23 risers, for the steps must be equal in height.

2178*a*. An easy mode of proportioning steps and risers may be obtained by the annexed method. Set down two sets of numbers, each in arithmetical progression; the first set showing the width of the steps, ascending by inches, the other showing the height of the riser, descending by half inches. It will readily be seen that each of these steps and risers are such as may suitably pair together. (Newland, *Carpenter's and Joiner's Assistant*, 1860, p. 197.) It is seldom, however, that the proportion of the step and riser is exactly a matter of choice—the space allotted to the stairs usually determines this proportion; but the above will be found a useful standard. In first-class buildings the number of steps is considered in the plan, which it is the business of the architect to arrange in accordance with the style of the edifice.

Treads. inches.	Risers. inches.
5	9
6	$8\frac{1}{2}$
7	8
8	$7\frac{1}{2}$
9	7
10	$6\frac{1}{2}$
11	6
12	$5\frac{1}{2}$
13	5
14	$4\frac{1}{2}$

2179. The width of the better sorts of staircases should not be less than 4 feet, to allow of two persons freely passing each other; but the want of space in town houses often obliges the architect to submit to less in what is called the *going* of the stair.

2180. The parts of every step in a staircase are one parallel to the horizon, which is called the *tread* of the step, terminated on the edge by a moulded or rounded *nosing*, and the other perpendicular to the horizon, which is called the *riser* of the step.

2180*a*. A curious instance of economy of material is given in *fig.* 781*a*., which shows the mode of getting six steps out of round timber 30 inches in diameter, being a saving of about ten per cent. upon the attempt to cut up square timber. Such solid steps were housed into the carriage; A showing the under side of it in relation to the step B. In straight flights the system of carrying solid newels from bottom to top of the staircase is one which has since been repeated successfully in iron construction. The ingenuity of the mediæval joiner in this subject is seen best treated in Viollet le Duc's dictionary. (See *par.* 2185.)

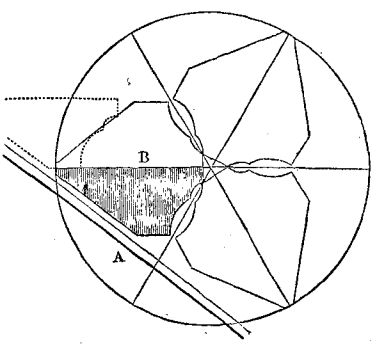

Fig. 781*a*.

2181. Stairs have many varieties of structure, dependent on the character, situation, and destination of the building. We shall now, therefore, describe the method of carrying up *dog-legged*, *bracket*, and *geometrical stairs*.

2182. A DOG-LEGGED STAIRCASE is one which has no opening or well-hole, and in which the rail and balusters of the progressive and returning flights fall in the same vertical planes. The steps in it are fixed to strings, newel, and carriages, the ends of the steps of the inferior kind terminating only upon the side of the string without any housing. Y and Z in *fig.* 782, are the plan and elevation of a staircase of this kind; AB is the lower newel whereof the part BC is turned. On the plan, *a* is the seat of this newel. DE and FG in Y are the lower and upper string boards framed into newels, KL is a joist framed into the trimmer I. The lines on the plan represent the faces of the steps in the elevation without the nosings. MO and FQ are called the upper and lower ramps, the method of drawing

which is as follows: — In the upper ramp, for example, produce the top of the rail HM to P; draw MN vertical, and produce the straight part ON of the pitch of the rail to meet it in N, making NO equal to NM. Draw OP at a right angle to ON. From P, as a centre, describe the arc MO, and then the other contrary curve, which will complete the ramp required. The *story rod* RS is in the fixing of all staircases a necessary instrument; for in fixing the steps and other work by a common measuring rule, bit by bit, the chances are that an excess or defect will occur, to make the staircase faulty; which cannot be the case if the story rod is applied to every riser, and such riser be regulated thereby.

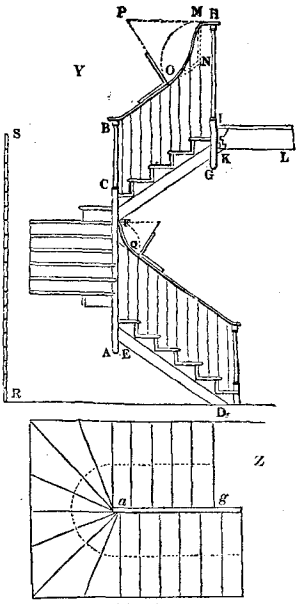

Fig. 782.

2183. A Bracket Staircase is one which has an opening or well, with strings and newels, and is supported by landings and carriages. The *brackets* are mitred to the end of each riser, and fixed to the string board, which is usually moulded like an architrave. In this sort of staircase the same methods are to be observed in respect of dimensions and laying off the plan and section as in a dog-legged staircase. Nothing is to be done without the story rod just described, which must be constantly applied in making and setting up the stairs. The method of forming the ramps and knees has been touched upon in the preceding article, and the few particulars we intend to give respecting scrolls and handrailing will be reserved for a subsequent page. In bracket stairs the internal angle of the steps is open to the end, and not closed by the string, as in common dog-legged stairs; the neatness also of the workmanship is as much attended to as in geometrical stairs. The balusters should be nicely dovetailed into the ends of the steps by twos, and the face of each front baluster is to be in a plane with the front face of the riser, and all the balusters being equally divided, the face of the middle one must of course stand in the middle of the face of the riser of the preceding step. The treads and risers are previously all glued up and blocked together, and when put in their places the under side of the step is nailed or screwed into the under edge of the riser, and then rough bracketed to the strings, as in a dog-legged staircase, in which the pitching pieces and rough strings are similar.

2184. A Geometrical Staircase is one whose opening is down its centre, or, as it is called, an open newel, in which each step is supported by one end being fixed in the wall or partition, the other end of every step in the ascent having an auxiliary support from that immediately below it, beginning from the lowest one, which, of course, rests on the floor. The steps of a geometrical staircase should, when fixed, have a light and clean appearance, and, for strength's sake, the treads and risers, when placed in position, should not be less than $1\frac{1}{8}$ inch thick, supposing the going of the stair or length of the step to be 4 feet. For every 6 inches in length of the step an eighth of an inch should be added. The risers should be dovetailed into the cover, and in putting up the steps, the treads are screwed up from below to the under edges of the risers. The holes for sinking the heads of the screws ought to be bored with a centre bit and fitted closely in with wood well matched, so that the screws may be entirely concealed, and appear as a uniform surface without blemish. Brackets are mitred to the risers and the nosings are continued round; but this practice induces an apparent defect, from the brackets, instead of giving support, being themselves unsupported, and actually depending on the steps, being indeed of no other use than merely tying together the risers and treads of the internal angles of the steps; and from the internal angles being hollow, except at the ends, which terminate by the wall at one extremity, and by the bracket at the other, there is an appearance of incomplete finish. The cavetto or hollow is carried all round the front of the slip, returned at the end, and again at the end of the bracket, thence along the inside of it, and then along the internal angle at the back of the riser.

2185. The ancient mode, however, was the best, in which the wooden was an imitation of the method of constructing geometrical stairs in stone, which will be found under Masonry, in the previous Section III.; that is to say, the making of the steps themselves solid, and in section of the form of a bracket throughout their length. This is a more expensive method, but it is a solid and good one, and is still practised on the Continent, especially in France. (See also par. 2180*a*.)

2186. In *fig.* 783. X is the plan and Y the elevation, or rather section, of a geometrical staircase. AB in X is what is called the *cur-tail step* (curved like the tail of a cur dog), which must be the first step fixed. CCC are the *flyers* supported from below by rough carriages, and partly from the string board DHEF in Y. The ends next the wall are sometimes housed into a notch board, and the steps then are made of thick wood and no carriages used. GGG are *winders* fixed to bearers and pitching pieces, when carriages are used to support the flyers. The winders are sometimes made of strong stuff firmly wedged into the wall, the steps screwed together, and the other ends of the steps fixed to the string DEHF. In all cases of wooden geometrical stairs their strength may be greatly augmented by a flat bar of wrought iron coinciding with the under side and screwed to the string immediately below the steps. HIK in Y is the wall line of the sofite of the winding part of the stairs, and LMN part of the rail supported by two balusters upon every step. Where the space of the going of the stairs is confined, the French have long since introduced, as in *fig.* 784., the practice of placing the balusters outside the steps, which affords more room for persons ascending and descending.

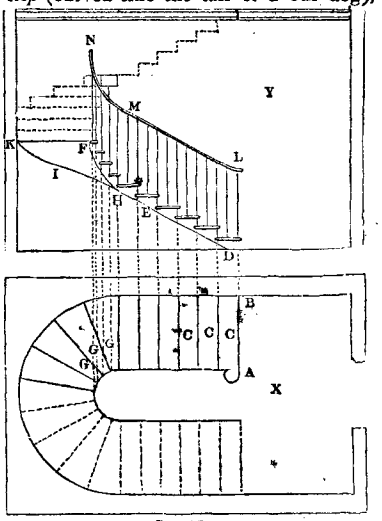

Fig. 783.

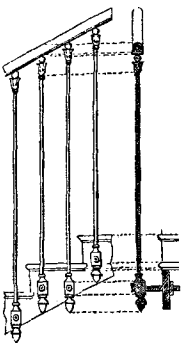

Fig. 784.

HANDRAILS AND CUR-TAIL STEP.

2187. The upper part of the fence formed by capping the balusters of stairs is called the *handrail*, whose use, as its name imports, is for a support to the hand in the ascent and descent of stairs. The hand, for support to the body, should glide easily over it without any strain, whence it is evident, that to be properly formed, it must necessarily follow the general line of the steps, and be quite smooth and free from inequalities. It must be obvious to the reader who has thus far followed us throughout the different previous portions of our labours, that the chief principle of handrailing will be dependent on the methods of finding sections of cylinders, cylindroids, or prisms, according to three given points in or out of the surface, or, in other words, the section made by a plane through three given points in space. The cylinder, cylindroid, and prism are hollow, and of the same thickness as the breadth of the rail, or the horizontal dimension of its section; and their bases, their planes or projections on the floor. Thus is formed the handrail of a staircase of a portion of a cylinder, cylindroid, or prism whose base is the plane of the stair, for over this the handrail must stand, and is therefore contained between the vertical surface of the cylinder, cylindroid, or prism. As the handrail is prepared in portions each whereof stands over a quadrant of the circle, ellipse, or prism of the base which forms the plane, such a portion may be supposed to be contained between two parallel planes, so that the portion of the handrail may be thus supposed to be contained between the cylindrical, cylindroidal, or prismatic surfaces and the two parallel planes. The parts to be joined together for forming the rail must be so prepared that in their place all the sections made by a vertical plane passing through the imaginary solid may be rectangular: this is denominated *squaring the rail*, and is all that can be done by geometrical rules. But handrails not being usually made of these portions of hollow cylinders or cylindroids, but of plank or thicknesses of wood, our attention is naturally drawn to the consideration of the mode in which portions of them may be formed from planks of sufficient thickness. The faces of the planks being planes, they may be supposed to be contained between two parallel planes, that is, the two faces of the plank. Such figures, therefore, are to be drawn on the sides of the plank as to leave the surfaces formed between the opposite figures, portions of the cylindrical, cylindroidal, or other surfaces required, when the superfluous parts are cut away. A mould made in the form of these figures, which is no more than a section of them, is called the *face mould*.

2188. The vertical, cylindrical, or cylindroidal surfaces being adjusted, the upper and lower surfaces must be next formed; and this is accomplished by bending another mould

round the cylindrical or cylindroidal surfaces, generally to the convex side, and drawing lines on the surface round the edge of such mould. The superfluous wood is then cut away from top to bottom, so that if the piece were set in its place, and a straight-edge applied on the surfaces so formed, and parallel to the horizon directed to the axis of the well-hole, it would coincide with the surface. The mould so applied on the convex side for forming the top and bottom of the piece, is called the *falling mould.* For the purpose of finding these moulds it is necessary to lay down the plan of the steps and rail; next, the falling mould, which is regulated by the heights of the steps; and lastly, the face mould, which is regulated by the falling mould, and furnishes the three heights alluded to.

2189. *Fig.* 785. exhibits two of the most usual forms of handrails. The upper part, A and B of the figure, are sections of the rail and mitre cap of a dog-legged staircase. Vertical lines are let fall from the section of the rail A, to the mitre in B; from thence, in arcs of circles, to the straight line passing through the centre of the cap at right angles to the former straight lines; then perpendiculars are set off and made equal in length to those in A. A curve being traced through the points gives the form of the cap. C is called a *toad's back rail,* and is used for a superior description of staircases.

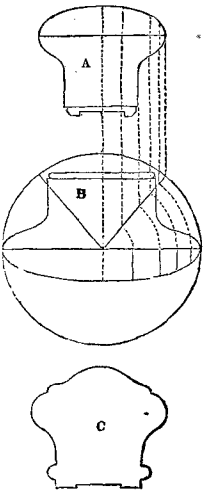

Fig. 785.

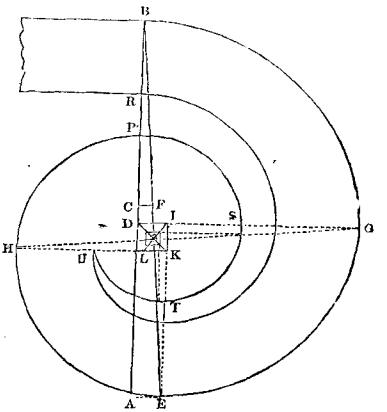

Fig. 786.

2190. *Fig.* 786. shows the method of drawing the scroll for terminating the handrail at the bottom of a geometrical staircase. Let AB be the given breadth; draw AE perpendicular to AB, and divide it into eleven equal parts, and make AE equal to one of them. Join BE, bisect AB in C and BE in F. Make CD equal to CF and draw DG perpendicular to AB. From F, with the radius FE or FB, describe an arc cutting DG at G. Draw GH perpendicular to BE cutting BE at O. Draw the diagonals DOK and IOL perpendicular to DOK. Draw IK parallel to BA; KL parallel to ID; and so on to meet the diagonals. From D as a centre, with the distance DB, describe the arc BG. From I as a centre, with the distance IG, describe the arc GE. From K as a centre, with the distance KE, describe the arc EH. From L as a centre, with the distance LH, describe the arc HP. Proceed in the same manner and complete the remaining three quarters, which will finish the outside of the scroll. Make BR equal to the breadth of the rail; namely, about two inches and a quarter. Then with the centre D and distance

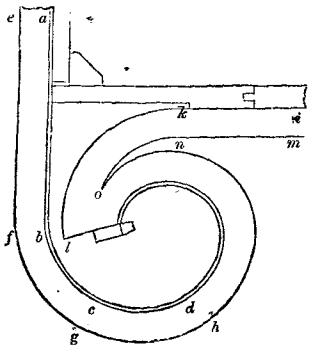

Fig. 787.

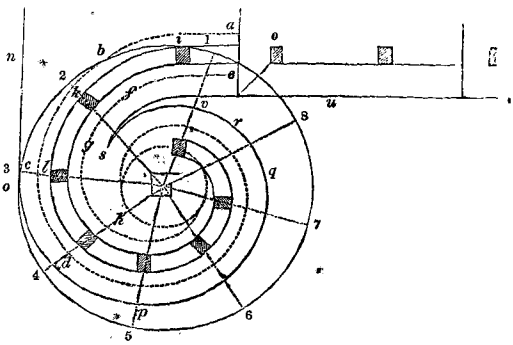

Fig. 788.

DR describe the arc RS, with the centre I and distance IS describe the arc ST, and with the centre K and distance KT describe the arc TU, and the scroll will be completed.

2191. *Fig.* 787. gives the construction of the cur-tail step, or that which lies under the scroll, *abcd* is the veneer that covers the riser ; *efgh*, the nosing of the cover or horizontal part of the step ; *ikl* the face of the string board, and *mno* the projection of the nosing.

2192. In *fig.* 788 is shown the cover board for the cur-tail step, *abcd* and *efgh* in dotted lines represent the plan of the scroll ; *opqrs*, the nosing of the cur-tail step ; *t, u, v, s*, the nosings and ends of the risers. The circle 1, 2, 3, &c. is described from the centre of the scroll, and divided into equal parts equal to the distances of the balusters from centre to centre, and lines are drawn to the centre of the scroll in order to ascertain the middle of the balusters, by giving a regular gradation to the spaces. The whole of the spiral lines in this and the previous figure are drawn from the same centres as the scroll.

BENCHES.

2192*a*. "It must be confessed," says Denison, in his *Lectures on Church Building*, 1856, page 242, "that our ancestors did not offer much temptation to people to come to church by the comforts they provided for them when they got there. Nothing, indeed, can be better for sitting in than some of the old stalls, such as those in King's College Chapel, where the back has a slope of one to four ; but most of the common old church seats are frightfully uncomfortable—the back of the seat ought to be inclined, especially when it rises as high as the shoulders. It is not of so much consequence when the seat backs are low, but even in them it is better to have a little inclination, about one in eight ; and above all things, the top rail ought *not* to project. The seats ought never to be less than 13 inches wide with a sloping back, or 14 inches with an upright one, and they will be all the better if they are an inch or two more. Nothing under 2 feet 10 inches at the very least will allow proper room for sitting, standing, and kneeling, especially if there are any divisions under the seats to prevent people from kicking their neighbours' hats, or appropriating their hassocks. Where it is necessary to save room in every possible way, it is not a bad plan to make the division under the seat only come down to 3 or 4 inches from the floor ; and never in any case ought there to be (what there often is) a thick rail or bar of wood lying along the floor and taking off an inch or more from the space for the feet. The book boards are best not sloping, which is of no use, but flat and narrow, just wide enough to lay a book upon shut, and to put the arms upon in kneeling. As regards the difficulty of finding a good place and proper height for the pulpit and reading desk, I know of no better advice to give upon the subject than to try various places before you finally fix upon any one, unless the construction of the church is such that there is one place marked out by nature (as we may say) as the proper one."

2192*b*. Examples of benches and bench ends are represented in so many publications that it is deemed unnecessary to give any illustration. Some cappings to benches, and edges to divisions, are shown in the section WOOD MOULDINGS in Book III. Those shown in Brandon's *Analysis*, and Bury's *Woodwork*, give the following dimensions :—

Name of Church.	Height.	Width.	Seat.	Opening.	
Comberton, Cambridge	2. 9	3. 4	1. 0	1. 6	
Bentley, Suffolk	2. 5	2. 10	0. 11½	1. 6	
Great Waltham, Essex, 1420	3. 1	2. 6	1. 2	1. 1	
Bishops Lydeard, Somerset	2. 10¼	2. 3½ / 2. 7½	0. 11	1. 0 / 1. 4	
Westonzoyland, Somerset	3. 3	2. 9½	—	1. 7	end 1. 4
Atherington, Devon	3. 9	—	0. 11½	—	
Ickleton, Cambridge	2. 4½	—	0. 10½	—	1. 10
Stalls, Bridgewater, Somerset	—	—	0. 11½	centre to centre	sitting 2. 3
„ Wantage, Berks	—	3. 5	—	1. 4½	1. 10

The rules of the Incorporated Society for Promoting the Building of Churches state, that "the distance from the back of one seat to that of the next must depend in great measure on the height of the backs. Where the funds and space will admit, convenience will be best consulted by adopting a clear width of 3 feet ; but a width of not less than 2 feet 8 inches from centre to centre will be allowed if the back of the seat is not more than 2 feet 8 inches in height. If a greater height be adopted, the distance from back to back must be increased one inch at least for every additional inch in height ; but under no circumstances must it exceed 3 feet. There must not be any projecting capping on the top of the backs. Facilities for kneeling in all cases to be provided. The width of the seat boards for adults to be not less than 13 inches. 20 inches in length must be allowed for each adult, and 14 inches for a child. Children's seats must be at least 26 inches from

back to front, and must have backs." Her Majesty's Commissioners for building new churches allow 20 inches by 34 inches for each sitting; free seats 20 inches by 27 inches, and 14 inches for children. Benches for free sittings are to be 3 feet, 4 feet 6 inches, or 6 feet long. The allowance made for each sitting in St. Paul's Cathedral is, as nearly as possible, 20 inches by 33 inches. From 4 to 5 square feet of floor is not too much space to be calculated for each person, allowing for gangways, communion table, &c.

2192c. Cloisters, porches, canopies, over-doors, stall-work, lych-gates, windows, staircases, bell-wheels and carriages, luffer or louvre boards, fencing, screens, pulpits, desks, lecterns, chests, tables, *cum multis aliis*, are amongst the many other productions of the joiner, being far too numerous to be described in detail herein.

FORMATION OF BODIES BY JOINING THEM WITH GLUE.

2193. The way in which bodies are glued up together for different purposes will be given below, and with them will close this section.

2194. *Fig.* 789. shows at A a section of two boards glued up edge to edge. At B the face of the same is seen. C shows the section of two boards glued edge to edge, each piece being grooved, and a *tongue* inserted at their junction. By similar means a board may be increased to any width, be the pieces whereof it is composed ever so narrow. D shows two boards fixed at right angles, the edge of one being glued on the side of the other. A block for the purpose of strengthening the joint is fitted and glued to the interior side.

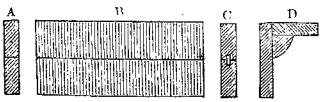

Fig. 789.

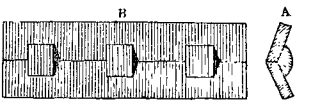

Fig. 790.

2195. *Fig.* 790. A is a section of two boards to be joined at an oblique angle. They are mitred and glued together with a block at the angle. B shows the inner sides of the boards so fixed. It is by repeating this operation that columns are glued up.

2196. *Fig.* 791. A is the section of an architrave. The moulding is usually, if not always, glued to the board; the vertical line therefore, showing the extreme boundary of the moulded part, is the section of the piece to be glued, B is the face of the architrave, C and D a section and front of it before it is moulded, E a section of it with the button and nail to show the way in which the two parts are glued together, and F shows the back of the architrave with the buttons which are used for the purpose of bringing the two surfaces to be glued together in contact, till after they are set and fully held together, being knocked off when the glue has become hard, and then the moulding shown at A and B is stuck.

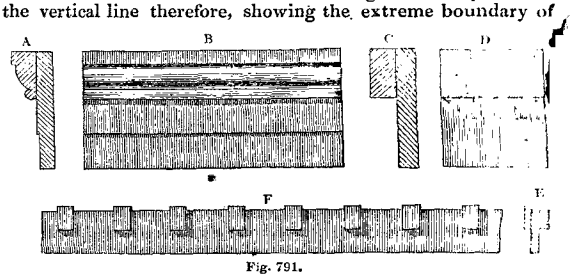

Fig. 791.

2197. *Fig.* 792. exhibits the method of gluing up a solid niche in wood where A is the elevation. The work is performed in the same way as if it were stone or brick, except that the joints are all parallel to the plane of the base, because of the difficulty of making a joint with curved surfaces, which would necessarily be the case if they all tended to the centre of the sphere. B and C are the two bottom courses, where the vertical joints are made to break, as seen in the elevation A.

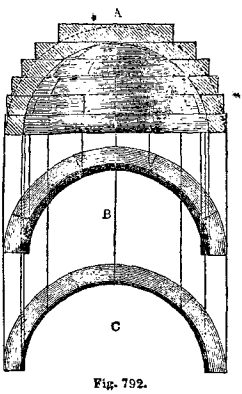

Fig. 792.

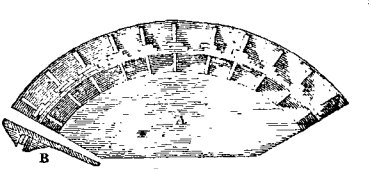

Fig. 793.

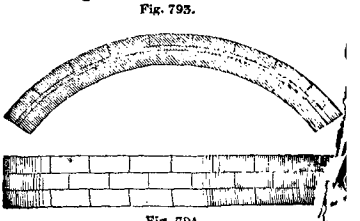

Fig. 794.

2198. In *fig.* 793. is exhibited the mode in which veneers are glued together for the purpose of forming cylindrical surfaces. Brackets with their faces upwards are nailed

a board. Their ends are perpendicular, and a cavity is left between them sufficient to receive the veneers and wedges. In A the thin part in the form of an arc shows the veneers as in the state of glueing, the wedges being on the convex side. B is a section of the board and bracket. The work when putting together should be dry and warm, and the glue should be hot. When this last has set hard, the wedges must be slackened, and the veneers, which now form a solid, taken out.

2199. *Fig.* 794. is a strong method of forming a concave surface by laying the veneer upon a cylinder, and backing it with blocks in the form of bricks, which are glued to the convex side of the veneers and to each other. The fibres of the blocks are to be as nearly as possible parallel to the fibres of the veneers. A is the section of the cylinder veneer and blocks, and B shows the convex side of the blocks.

2200. *Fig.* 795. is another mode of glueing veneers together with cross pieces screwed to a cylinder, the veneers being placed between the former and the latter.

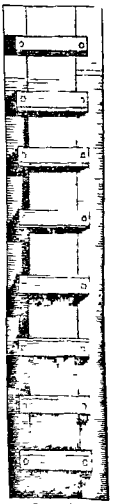

Fig. 795.

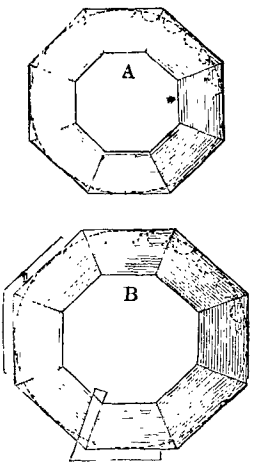

Fig. 796.

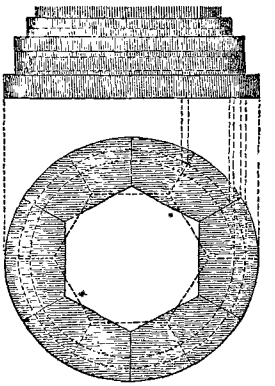

Fig. 797.

2201. In *fig.* 796. is shown the method of glueing up columns in pieces, which here are eight in number, each being glued to the other after the manner of *fig.* 790. The workman should be careful to keep the joints out of the flutes, when the columns are to be fluted, by which the substance will be more likely to prevent the joints giving way. A is a section of the column at top, and B at the bottom. After glueing together, the octagons and mitres should be correctly laid down for the true formation of the joints. In B are shown two bevels, one for trying the mitres, and the other for trying the work when put together.

2202. *Fig.* 797. is the mode of glueing up the base of a column. It is formed in three courses, the pieces in each of which are made to break joint over one another. The horizontal joints of the courses must be so adjusted as to fall at the junction of two mouldings, forming a re-entering angle. After the glue is set quite hard, the rough base is sent to the turner, by whom it is reduced into the required profile. The fibres of the wood should lie horizontally, in which direction the work

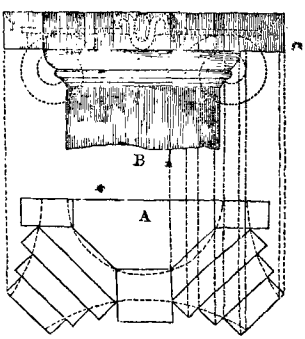

Fig. 798.

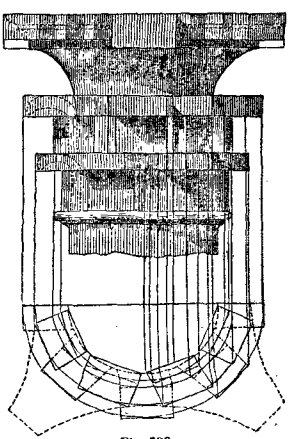

Fig. 799

will stand much better than when they are vertical. A is the plan of the base inverted, and B is the elevation.

2203. The formation of a modern Ionic capital is given in *fig.* 798., wherein A is the plan inverted, showing the method of placing the blocks; and B is the elevation.

2204. *Fig.* 799. is the method of glueing up for the leaves of the Corinthian capital, A is the plan inverted, and B is the elevation. The abacus is glued up in the same manner as in the preceding example.

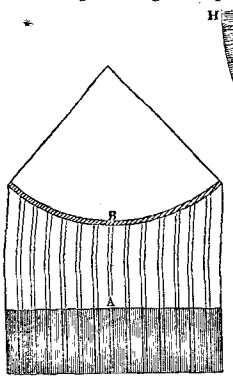

Fig. 800.

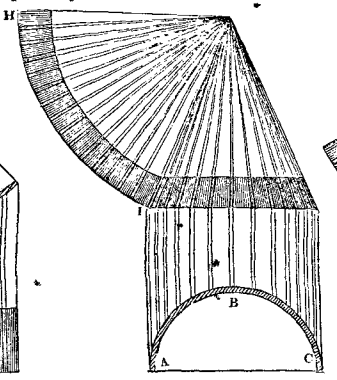

Fig. 801.

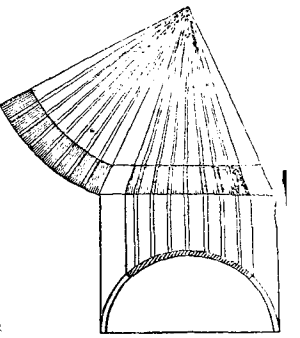

Fig. 802.

2205. *Fig.* 800. exhibits the mode of forming a cylindrical surface without veneers, by means of equidistant parallel grooves, A is the elevation, and B the plan.

2206. *Fig.* 801. exhibits the method of covering a conic body. It is, in fact, no more than covering the frustum of a cone, and is accomplished by two concentric arcs terminated at the ends by the radii. The radius of the one arc is the whole slant side of the cone, that of the other is the slant side of the part cut off. In this case, the grooves are directed to the centre, and filled in with slips of wood glued as before. The plan is shown by the circle ABC. The arc HI must be equal to the circumference ABC.

2207. *Fig.* 802. shows the same thing for a smaller segment.

2208. *Fig.* 803. shows the manner of glueing up a globe or sphere by the same method. A is the face of the piece; B the edge showing the depth of the grooves; C shows the mould for forming the piece to the true curvature; and D the faces of two pieces put together.

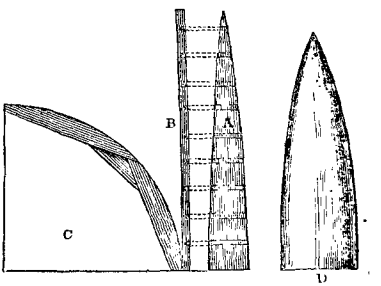

Fig. 803.

Sect. VI.

SLATING.

2209. An account of the materials used by the slater has been detailed in Chap. II. Sect. IX. The tools used by this artificer are the *scantle*, which is a gauge by which slates are regulated to their proper length; the *trowel*; the *hammer*; the *zax*, an instrument for cutting the slates; a small *handpick*, and a *hod* and a *board* for mortar. The *zax* is an instrument made of tempered iron, about 16 inches long and 2 inches wide, like a large knife bent a little at one end, with a wooden handle at the other, and having a projecting piece of iron on its back, drawn to a sharp point, to make holes in the slates for the nails, the other side being used to chip and cut the slates to their required size, as when brought from the quarry they are not sufficiently square and cleaned for the slater's use. The places for the nail holes are marked usually on the slate where they have to be punched, with a gauge, and then the iron of the *zax* is struck through the slate. Each slate has two holes; large slates require three. A better mode of obtaining the place for the holes is to mark a plank with two small pieces of wood across it, at the distance required; the position is thus shown at once.

2210. Slating is laid in inclined courses, beginning from the eaves and working upwards, the courses nearest the ridge of the roof being less in width than those below. The *lap* of one slate over another is called its *bond*, and it is the distance between the nail of the under slate and the lower end of the upper slate. The *bed* of a slate is its under side, and the upper side is called its *back*. The part of each course which is exposed to the weather is called its *gauge*, *bare*, or *margin*. The slates are nailed to close or open boarding, lying on the back of the rafters, with nails, which should be of copper or zinc. If iron nails are used they should be well painted. The operation of cutting or paring the side and bottom edges of the slates is called *trimming* them; but the head of the slate is never cut. In that part the holes were formerly pierced by which the nails pass to the boarding. This boarding (or *sarking*, as it is called in the north of Great Britain) is usually $\frac{3}{4}$ inch to $1\frac{1}{4}$ inches thick, rough, of equal thickness, and well secured to the common rafters. A good practice obtains of bedding slates in mortar, on boarding, which gives them a sound bearing, especially if the roof will have to stand much wear from persons passing along the gutters, or over the ridge, for repairs and other purposes.

2210*a*. Another method of forming a roof, as lately employed by some architects, consists in slating on boards fixed to purlin-rafters, without any common rafters, as shown in *figs.* 695*a*. and 697. The purlins are placed somewhat closer than when rafters are used; the boards are $1\frac{1}{4}$ inches thick, usually placed diagonally. It makes very sound work, and saves height, where that may be an object. Another method, as noticed in par. 2285, is to nail the boarding on to common rafters laid as purlins, as shown in *figs.* 695 and 696.

2210*b*. The common method of slating is to nail the slates to laths or battens, as in tiling, but a house so done is more liable to be affected with the various changes from heat to cold than by the other system. These laths are cut to boards of 20, 25, 30 or 36. Thus a board $12 \times 9 \times 3$, cut 3 deep and 4 flat, equals 1 board 20. If cut 4 deep and 4 flat, equals 1 board 25. If cut 4 deep and 5 flat, equals 1 board 30. If cut 5 deep and 5 flat, equals 1 board 36. Slating laid on battens, at places on the sea coast, and as usual in work in Ireland, is either wholly "rendered" with lime and hair on the under side, or only the under edges and laths are thus secured. Without this precaution the slates rattle, and the driving winds get under them, tending to strip the roofs. Rendering, properly done, lasts as long as the slates exist in a perfect state.

2210*c*. Open or ventilated slating, which is nearly equally as waterproof as the usual method of slating, will save one-third of the quantity per square.

2210*d*. *Felt.* Slate is also laid on *felt*, on $\frac{3}{4}$ inch boarding. Croggon's patent *asphalte roofing felt* is impervious to rain, snow, and frost, and is a non-conductor. From its anti-corrosive properties, it is of service when placed between iron and wood and between metals. It is manufactured of any required length, by 32 inches wide. There is some risk of dry rot occurring, however, by using it thus; the better plan is to lay the felt on boards, and then to batten for the slates over the felt, so as to leave an air space between the felt and the slates. Its general weight is about 42 lbs. per square. *Non-conducting felt* is formed entirely of hair, and is used for covering boilers, steam-pipes, &c., for the purpose of preventing the radiation of heat. When applied to boilers, a cement of 2 parts of white lead, $1\frac{1}{2}$ parts of red lead, 4 parts of whiting, is mixed with boiled linseed oil; after being spread over the felt, the whole is patted down on the boiler, and in a short time the felt firmly adheres. No cement is needed for steam-pipes, the felt being wrapped round and secured by twine. Sheets of this felt are made 32 inches by 20 inches; and of the following weights:—No. 1, 16 oz.; No. 2, 24 oz.; No. 3, 32 oz.; No. 4, 40 oz.; No. 5, 48 oz. This dry hair or inodorous felt is also useful for deadening sound, by cutting it into 2 or $2\frac{1}{2}$ inch strips, and laying it on the joists under the floor boards; also as lining to walls and floors; and for iron houses to equalise the temperature.

2210*e*. Felt is also applied for forming roofs of temporary buildings. It has been suggested for permanent buildings, but to that employment of it we must withhold our approval. The rafters may be about 3 inches by $1\frac{1}{4}$ inches, placed 20 to 24 inches apart, laid at a pitch of 2 or 3 inches to the foot, and covered with $\frac{1}{2}$ inch boarding. The felt is to be stretched tight, overlapping one inch at the joints, nailed with twopenny fine clout nails, first heated and cooled in grease, about $1\frac{1}{2}$ inches apart; copper nails are preferable. The whole roof is then to have a good coating of hot coal tar and lime, in the proportion of 2 gallons of the former to 6 pounds of the latter, well boiled together, put on with a common tar mop, and while it is soft some coarse sharp sand sifted over it. The gutters are made of two folds, cemented together with the boiling mixture. The coating to the roof must be renewed every fourth or fifth year, according to the climate. The felt is found to last better, if it be not made to adhere by any mixture to the boarding.

2210*f*. Felt for sheds, or occasional purposes, may be put up without boarding; the rafters in this case would not exceed 3 inches by $1\frac{1}{4}$ inches, placed at a distance of 30 inches apart. To prevent the felt bagging, battens, or slighter rafters, of about 2 inches by 1 inch, are placed between the others. To such roofs the felt must be laid from eaves to eaves, nailing through the overlap into the main rafter. The pitch of this roof should be about 6 inches to the foot. The "ventilated" slating will bear an economical contrast, provided the smaller size of slates be used, and is more durable

2210*g*. Slating is sometimes laid lozengewise, but it is much less durable than when laid in the usual method. It is introduced for the sake of ornamental effect. The ends of the slates are also rounded, or cut angleways to a point, or the angles only cut off; or, if the slates be of a small size, they are set angleways over courses with square ends. These are all shown in an excellent article in Viollet le Duc's *Dictionnaire*, s.v. Ardoise. Slating is also made to have a decorative effect by forming zigzag patterns with red coloured slates among blue slates; or a few courses of the one above a larger number of the other.

2210*h*. Several years ago, a patent was obtained for forming roofs with slate slabs without boarding or battens. In this the slates were all reduced to widths equal to the distance between centre and centre of the rafters. On the backs of these last they are screwed by two or three strong inch and half screws at each of their ends. Over the junctions of the slates, on the backs of the rafters, fillets of slates about two and a half or three inches wide, bedded in putty, are screwed down, to prevent the entrance of rain. The handsome regular appearance of this sort of slating gained it at first much celebrity; but it was soon abandoned, on account of the disorder it is liable to sustain from the slightest partial settlement of the building, as well as from the constant dislodgement of the putty, upon which greatly depended its being impervious to rain.

2211. Subjoined is a succinct account of the different sorts of slates brought to the London market, and enumerated in the order of their goodness and value.

2211*a*. *Westmoreland slates.* These are from 3 feet 6 inches to 1 foot in length, and from 2 feet 6 inches to 1 foot in breadth. They should be nailed with not less than sixpenny and eightpenny copper or zinc nails (iron nails should never be used); and a ton in weight of sized slates will usually cover about two squares and a quarter. The weight of the coarsest Westmoreland slates is to that of common tiling as 36 to 54.

2211*b*. *Welsh rags* are next in goodness, and are nearly of the same sizes as those last mentioned; but a ton of these will cover only from one square and a quarter to one square and three quarters.

2211*c*. Table of the Names and usual Sizes of Slates,

With the squares a thousand (1200) will cover according to their size, and the gauge at which they are laid, as stated in various works. * Denotes best Welsh roofing sizes.

Name.	Size. Inches.	Cover about Squares.	Cover about Squares.	Weight per 1200. Cwts. 1st quality.	Weight per 1200. Cwts. 2nd quality.
Queens	32, 34, 36 × 16, 17, 18	-	-	-	-
Princesses	30 × 15	$16\frac{3}{4}$	-	115	
Ditto	28 × 14	$14\frac{1}{2}$	-	97	
Ditto	*24 × 14	$12\frac{3}{4}$	$12\frac{1}{4}$	70	90
Empress	26 × 16	-	-	95	
Ditto, small	26 × 14	-	-	90	
Duchesses	*24 × 12	11	10	60	80
Ditto, small	*22 × 12	-	-	55	
Marchionesses	22 × 12	$9\frac{1}{2}$	9	55	70

Singles	-	-	1	-	-
Headers	*12 × 6	-	-	14	
Ditto	*14 × 12	-	-	33	
Ditto	*13 × 10	-	-	26	

During last century, when building works were executed with more regard to durability, a thousand duchesses were said to cover 9 squares; countesses, 6 squares; ladies, 3 squares; and doubles, 2 to 2½ squares.

2211*d*. Slates are now split so thin, that in specifications it is desirable to state the weight per square of the slating required. The scientific journals have lately noticed that at the Rhiwboyfdir Slate Company's quarries, sheets of slate 8 feet long and $\frac{1}{32}$nd part of an inch were obtained. the length being generally 16 inches. The grain must, of course, be very fine to permit of so thin a cleavage.

2211*e*. The strength of slate 1 inch thick is considered equal to that of Portland stone 5 inches thick. A foot superficial weighs from 11¼ to 14 lbs. Slates of the usual thickness will not bear much heat before cracking: the thicker the slate the more readily does it crack with heat; and they will fly at once if cold water be poured suddenly upon them when in a heated state.

2211*f*. The *Tavistock slates* were sold by the thousand of ten hundred, which quantity covered about three squares and forty feet.

2211*g*. Horsham slate, obtained in Sussex, is a limestone, and is found to have no limit to its durability; but being very heavy, proper preparation is needed for it, as timbers of much greater scantling than usual are required.

2211*h*. French slates, formerly used in London to some extent, are very light, and must therefore only be used on boards; otherwise the wind would act upon them. In France they are bedded in plaster on the boarding.

2211*i*. The ridge, hips, and valleys of a slated roof were formerly always covered with lead. The valleys are still usually so formed, but slate has been introduced for the two former. The pieces require to be cut truly square, screwed to the boarding, and the joints and heads secured with putty or white lead. For hips and ridges, *slate roll ribbing* is often employed (*fig.* 803*a*.). Shorter slates, A, are first nailed to each side of the ridge-piece, C, or of the hip rafter, to form the saddle, and then the slate roll B is put on and secured by screws through the top. This roll is made also with rebated joints, but it is obviated by the roll breaking joint with the saddle. The roll, as shown in the figure, is sometimes attached to one side of the saddle, which must be made according to the pitch of the roof.* The 3-inch diameter roll has a 7-inch width of saddle on each side; the 2½-inch a 6-inch; and the 2-inch a 5½-inch saddle. There are 175, 225, and 320 feet in a ton of the ribbing; and 400, 560, and 700 feet of the ribbing.

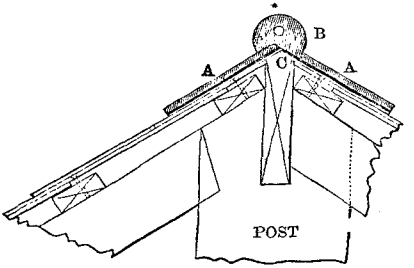

Fig. 803*a*.

2211*k*. The edges of the slates next a wall, either at the head or sides of a roof, have to be protected. This, in the best work, is effected by lead flashings (*par.* 2214.). In the former case, it is laid on the head of the slate for about 5 to 7 inches, and then turned up against the wall for about the same height, and secured by holdfasts; it may also be either turned over into a course of bricks, and the brickwork continued up, or the turned up edge is protected by a lapping of lead inserted in the brickwork. This lapping, in commoner work, is replaced by cement. At the edge of the roof against a wall, lead is likewise placed in a similar manner; but as the lapping cannot be laid in a straight joint, it is cut in a zigzag form, called "stepping," to each course of bricks. Of late years this lead flashing is entirely replaced by filleting of lime and hair-plaster; of gauged stuff, being lime and cement mixed; or of cement and sand. But as these materials crack and fall away in a few years, the filleting has to be looked to periodically or whenever damp makes its appearance. Zinc also takes its place, but is not so effective, as it is more difficult to dress it to the surface of the slates.

2211*l*. In exposed situations, where filleting cannot be trusted, and lead is too expensive, various contrivances have been made for preventing the entrance of wet. One of these consists in forming a small gutter between two rafters, lining it with lead, turning one side of the lead under the slates, and turning up the other side against the wall, and cementing over it. Another good method is to cement a row of tiles against the wall above the slates, and when dry to cover the tiles and wall with cement, tucking it well into all the crevices.

2211*m*. The mediæval method of easing the line of tiling at the foot of the framing deserves some notice; thus, as shown in *fig.* 701*e*., it appears that the use of chantlates, A, frees the tie-beams, tassels, and other timber, except plates, from all contact with the masonry; and, as a matter of course, from any consequent tendency to rot. This method seems more advantageous than that of beam-filling, which is altogether prevalent at the

present time, in order to keep out draughts, but it requires care in closing the work. Tiling has been already described in the section Bricklaying.

2211*n*. In many churches with open roofs, the solid rafters, without any under panelling or boarding, may be seen covered with rough slabs of boarding, having large fissures through which the lead is visible. Great inconvenience is often felt in roofs so constructed during the autumn and winter months, when, upon sudden alteration of temperature, condensation takes place under the lead, and the drops of water fall in almost a shower. This defect has been the cause for ceiling many open roofs. A space of two inches left between the inner boarding and the outer covering has been found to be sufficient to obviate this discomfort. Felt (*par.* 2210*d.*) is also sometimes used, to assist in remedying the evil.

2211*o*. In Pembrokeshire, slate is used for everything. For posts and rails of the same scantling as if for wood. The walls of buildings are of square blocks, rough casted. A range of stabling might be erected of rough blocks, with the door and window-frames of worked slate. A prejudice exists against the use of squared blocks without plastering them, on the ground that they admit damp. It was found that if there was the smallest perforation in the slate; or if, as was often the case from the want of absorption, the joints were not perfectly close, the damp is driven through. The defect might, perhaps, be obviated by laying every block with the bed slightly inclining outwards.

2211*p*. *Slabs of slate*, sawn, self-faced, and planed, are now extensively manufactured at all the large quarries. They are usually in $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{2}$, and 3 inch thicknesses. A quarter of an inch is required for each face planed from the rough, and they are sanded in addition afterwards. The best quality Bangor slabs can be obtained in sizes varying from 4 to 6 feet long, or from 2 to 3 feet wide; and from 6 to 8 feet long, or from 3 to 3 feet 6 inches wide. The second quality slabs, quarry planed, are under 6 feet long or 3 feet wide.

2211*q*. The purposes for which slate slabs are now used are multifarious. Amongst them are: cisterns (Plumbery) from $\frac{3}{4}$ inch to 2 inches thick; sinks of inch slate, 4 inches deep inside, either bolted together as cisterns, or with flush ends, planed both sides, and screwed; troughs; filters, baths, 2 feet wide, 2 feet high, 4 feet 9 inches at bottom and 5 feet 9 inches at top, all outside dimensions, of plain slate, sanded inside, or enamelled self-colour inside, or enamelled Siena marble inside, and so on; urinal back and divisions, plain or enamelled, fitted with angular earthenware basin, flat back basin, hollow back cradle basin, square basin, or with slate apron only; linings to damp walls; panels of doors; table tops; billiard-tables; shelving to dairies and pantries; fittings for wine bins, with permanent or with moveable shelves and ledges; steps; and landings.

2211*r*. *Enamelled slate*, as it is called, is worked for chimney-pieces, to represent marbles; for covers to stoves and hot water coils, besides many other decorative purposes. The process, which is simply painting dried at a great heat, requires to be well done to be really lasting. There are, of course, imitations of the process, but these are defective in that quality.

2211*s*. Thatching is an admirable covering for securing warmth in winter, and coolness in summer; but it is subject to injury by birds, and to risk from fire. It was much used for churches in Norfolk and Suffolk (*fig.* 701*n.*). The thatcher requires a common *stable fork*, to toss up the straw together before being made into bundles; a *thatcher's fork*, to carry the straw from the heap up to the roof; a *thatcher's rake*, to comb down the straw straight and smooth; a *knife*, or *eaves' knife*, to cut and trim the straw to a straight line; a *knife* to point the twigs; a half *glove* of leather, to protect the hand when driving in the smaller twigs or *spars*; a long flat *needle*; a pair of leathern *gaiters* to come up above the knees, used when kneeling on the rafters; and a *grit-stone* to sharpen the knives. Wheat straw lasts from 15 to 20 years; and oat straw, about 8 years. Reed thatching, as done in the West of England, is the truss after the ears have been *cut off*, leaving the clean, sound pipe straw, of which a thickness of 3 inches is laid on the common thatching with *spars* only. The materials required are straw or reeds, laths, nails, withes and rods. A load of straw, laid on about 12 to 16 inches in thickness, will do a square and a half; a bundle of oak laths, $1\frac{1}{4}$ inches wide, and from $\frac{1}{4}$ to $\frac{3}{8}$ths thick, nailed about 8 inches apart, 1 square; a hundred of withes, 3 squares; a pound of rope yarn, 1 square; 100 of rods, 3 squares; and $2\frac{1}{2}$ hundred of nails, 1 square. The fish house at Meare, Somersetshire, of about the middle of the 14th century, still retains its thatched roof. Probably thatched roofs were ornamented by a species of cresting, for in some parts of the country the withes or willow twigs that bind the thatch are sometimes arranged on the tops of ricks and cottages in an interlacing manner, terminating with a spike with a rudely formed cock. Viollet le Duc alludes to the custom of forming the ridge in mud, in which plants and grasses were inserted to prevent the earth being dissolved and washed away by the rain.

Sect. VII.

PLUMBERY.

2212. The plumber has but few working tools, for the facility with which the metal in which he works is wrought does not render a variety necessary. The principal are—a heavy iron *hammer*, with a short but thick handle. Two or three different sized wooden *mallets*, and a *dressing and flatting tool*, which is made of beech wood, usually about 18 inches long and 2½ inches square, planed smooth on one side, and rounded on the other or upper side. It is tapered and rounded at one of its ends for convenient grasping by the workman. Its use is to stretch and flatten the sheet lead, and dress it into the shape required for the various purposes whereto it is to be applied, by the use of its flat and round sides as wanted. The *jack and trying planes*, similar to those used by carpenters, for planing straight the edges of their sheet lead when a regular and correct line is requisite. They also use a line and roller called a *chalk line*, for lining out the lead into different widths. Their cutting tools are *chisels* and *gouges*, of different sizes, and *cutting knives*. The latter are for cutting the sheet lead into strips and pieces to the division marked by the chalk line. They use also *files* of different sizes for making cistern heads to pipes, for pumpwork, &c. For the purposes of soldering, they have a variety of different sized *grozing irons*, which are commonly about 12 inches long, tapered at both ends, the handle end being turned quite round to allow of its being held firmly in the hand whilst in use. The opposite end is spherical, or more usually spindle-shaped, and proportioned to the different situations for which they are required. The *grozing iron* is heated to redness when in use. The *iron ladles* are of three or four sizes, and used for the purpose of melting lead or solder. The plumber's *measuring rule* is 2 feet long, in three parts, each of 8 inches. Two of the legs are of box-wood, and the third of steel, which is attached to one of the box legs by a pivot whereon it turns, and shuts into the other legs in a groove. The steel leg is useful for passing into places which the plumber has to examine, into which anything thicker would not easily enter, and it is often used also for removing oxide or other extraneous matter from the surface of the heated metal. The plumber moreover is provided with *centre bits* of all sizes, and a stock to work them in, for perforating lead or wood where pipes are to be inserted, as well as with *compasses*, for striking out circular portions of lead. *Scales and weights* are also in constant requisition, as nothing done by the plumber is chargeable till the lead is weighed.

2213. The method most commonly adopted in laying *sheet lead* for terraces or flats, is to place it on a surface as even as possible, either of boarding or plastering. If boards are employed, they should be sufficiently thick to prevent warping or twisting, which, if it occur soon, causes the lead to crack or to become unsightly. As sheets of lead are not more than about 6 feet in width, when the area to be covered with them is large, joints become necessary, which are contrived in various ways to prevent the wet from penetrating. To do this, the best method is that of forming *rolls*, which are pieces of wood about 2 inches square extending in the direction of the joint, planed and rounded on their upper side. These being fastened under the joints of the lead between the edges of the two sheets which meet together, one is dressed up over the roll on the inside, and the other over both of them on the outside, whereby all entry of the water is prevented. No fastening is required other than the adherence of the lead by close hammering together and down on the flat; indeed, any fastening would be injurious, as by it the lead would not have free play in its expansion and contraction from heat and cold. When rolls are used, the rule should be specially enforced of turning the open sides or laps from the south-west, west, or south, wherever practicable, so as to ensure the lap from being forced up by the wind, and thereby the water consequently blown in. If *rolls* are not employed, which from their projection are in some cases found inconvenient, *seams* are substituted for them; but they are by no means equal to the roll either for neatness or security. They are formed by merely bending up the two edges of the lead, and then over one another, and then dressing them down close to the flat throughout their length. Though some solder the joints, it is a bad practice, and no good plumber will do it, for the same reason as that just given in respect of fastenings in flats. A lead *flat*, as well as a gutter, should be laid with a fall to keep it dry. A quarter of an inch in a foot is sufficient inclination for lead, if the sheets be 20 feet long, so that in this case they will be 5 inches at one end higher than at the other. This *giving a current*, as it is called, is usually provided for by the carpenter previous to laying the lead.

2214. Round the extreme edges of flats and gutters where lead is used, are fixed pieces of milled lead which are called *flashings*. When the lead work is bounded by a wall of

brick or stone work, the flashings are passed on one edge into and between a joint of the work, and the edges of the flat or gutter being bent up, the other edge of the flashing is dressed over it. If there be no joint into which the flashing can be inserted, it is fastened on that side with wall hooks (*par.* 2211*k.*). *Drips* in flats and gutters are used when the length of the gutter or flat is greater than the length of the sheet of lead, or sometimes for convenience, or to avoid joining lead by soldering it. Some architects place them every 6 or 8 feet, which however good in a box or parallel gutter, it raises an ordinary gutter too much, and causes great width of lead at the head. They are formed by raising one part above another, and dressing the lead round, as has been described for rolls. No sheet should be laid in greater length than 10 or 12 feet without a *drip*, to allow of expansion and contraction. Small *cisterns* are often sunk in gutters to collect the water before passing off into the head of the down pipe. The cistern has usually over it a perforated lead *rose*, to prevent dirt, leaves, &c. passing down with the water.

2215. The work of the plumber is estimated by its weight and the time employed in fixing it.

2215*a*. The thickness of sheet lead varies from 5 to 12 lbs. in weight to the superficial foot, and is used in covering large buildings, in flats or slopes, for gutters, the hips, ridges, and valleys of roofs, the lining of cisterns, &c. Thus 7lb. lead is commonly used for roofs, flats, and gutters; it is the least thickness in which *bossing* can be properly done. 8lb. lead is a better quality for all these purposes. 6lb. lead is used for hips and ridges; this is the thinnest quality for such purposes. 5lb. lead is used for flashings. It is said that 16lb. lead was used on the earlier mediæval churches. The following thicknesses, obtained from Hurst, *Surveyors' Handbook*, may be compared with the Birmingham Wire Gauge given in *par.* 2254, Sect. x.

Table I. of the Thickness and Weight of Lead, per Superficial Foot.

Thickness or Decimal of an Inch	1/16 ·0625	1/8 ·125	3/16 ·1875	1/4 ·25	5/16 ·3125	3/8 ·375	7/16 ·4375	1/2 ·5

Pounds	33·375	37·083	40·792	44·500	48·208	51·917	55·625	59·333

Table II. of the Weight and Thickness of Lead, per Foot Superficial.

Weight in Pounds.	Thickness in inches.	Weight in Pounds.	Thickness in inches.	Weight in Pounds.	Thickness in inches.
1	0·017	6	0·101	11	0·186
2	0·034	7	0·118	12	0·203
3	0·051	8	0·135		
4	0·068	9	0·152		
5	0·0 5	10	0·169		

2215*b*. Lead is generally cast about 7 feet wide and about 33 feet in length, but its width and length depend upon the margin which is cut off after casting, as the scum, &c. is driven to those parts. This may reduce it about 6 inches in width and 18 to 24 inches in length. Lead is now cast to the above-named weights, and also "bare," according to the directions of the contractor. The architect, to do justice to his employer, should carefully ascertain for himself the weight and size of the sheet of lead from which the piece is cut. It is usually marked or painted upon it. A small piece is not a true test either for weight or gauge, and the edge is sometimes cut on a bias. The best direction is that it should weigh over the weight specified.

2216. A hundred weight of sheet lead will usually cover on a platform, roof, gutter, &c. at 4 lbs. = 28 ft.; 5 lbs. = 22 ft. 5 ins.; 6 lbs. = 18 ft. 8 ins.; 7 lbs. = 16 ft.; 8 lbs. = 14 ft. 9 lbs. = 12 ft. 6 ins.; and 12 lbs. = 9 ft. Old lead weighed for recasting has generally a deduction made of 6 lbs. per cwt. for waste, &c.

2217. Lead is used to fasten iron cramps, posts, and bars into masonry by filling up cavities between them. Sheets of thin lead are sometimes placed between the drums of columns (par. 1925*a*.), as well as in the bed joints of wrought stone arches, to distribute

the pressure between the stones. Lead work treated ornamentally for ridges, and hips of roofs, knobs, vanes, &c., as during the Mediæval period, is superseded in the present day by cast and wrought iron, and by zinc work. See essay in *Builder*, 1856, p. 410.

2218. We do not think it necessary to describe at length the machinery of a *water closet*. Every one knows that the principle on which it is formed is that of a head of water in a cistern placed above it, which by means of a lever attached to a valve in the cistern allows a body of water to rush down and wash the basin, whose valve is opened for the discharge of the soil at the same moment that the water is let down from the cistern. Various instruments for this purpose have been patented; the excellent one made by Bramah, was among the first. Underhay's patent, among the latest, does away with all wires and cranks, the supply pipe being constantly filled with water. The reader will obtain by the inspection of one a far better notion than words or diagrams will convey. The apparatus of a water closet has also been made self-acting, either by opening the door of the closet; by lifting the lid of the seat of the closet; or by depressing the seat itself. One of the most simple and efficient pans is that called by Messrs. Doulton the *enamelled stoneware closet pan, figure D*, which with pan and trap complete, is sold at 3*s*. 9*d*. each. A cistern is described in par. 2223*f*.

2218*a*. In opposition to *water* closets, *earth* or *dry soil* closets have lately been much advocated. The deposits are at once deodorised by coal ashes or earth, which absorbs the ammonia and other fertilizing properties, for removal to the garden or field. It may be considered more serviceable where there is a deficient water supply or a want of proper drainage, and in country, rather than in town, localities.

2218*b*. The importance of good stench traps to drains is not to be overrated. The usual iron *bell trap*, as supplied to a sink, or let into a pavement, is sufficient as long as the bell remains perfect. Tye and Andrews have patented a useful *syphon trap* for the same services; and Cottam has also a cast iron trap or "effluvium interceptor." Beard and Dent have patented a *cast lead pipe trap* of 2 and 4 inches diameter, and claim for it that it is of pure and solid lead without solder or seam of any kind; as clear inside and out as any pipe made by hydraulic pressure; of a perfectly regular substance throughout; and that being composed of one metal, it is not subject to expansion, nor liable to be affected by the gases, which tend to destroy the ordinary trap. All these traps will only continue effective as long as water remains either in the cup or at the syphon bend, a fact which is either not known to, or forgotten by very many housekeepers, who complain of bad smells from the drains in summer time, or after some days of dry weather.

WATER SUPPLY.

2219. As it is a branch of the plumber's trade to find and fix the pumps for the supply of water to a dwelling, we think it right to furnish a description of the three sorts commonly used, which are the *lifting*, the *common*, and the *force pump*.

2220. *Fig.* 804. is a diagram of a *lifting pump*, in which ABCD is a short cylinder submerged in the well or other reservoir, whence the water is to be raised. In this cylinder a valve is placed at *x*, above which the pipe or tube CE is carried upwards as high as is requisite for the delivery of the water. In the cylinder AD a water-tight piston moves vertically, being worked by rod or framework as seen in the diagram. To this piston is fixed a valve at *v* opening upwards. On the descent of the piston the pressure against the water opens the valve *v*, and the cylinder between the two valves is filled with the water. When the piston is then raised, the water between the valves being pressed upwards against the valve *x*, opens it, and is driven into the tube CE, from which, on the renewed descent of the piston, its return is intercepted by the valve *x*. The water follows the piston in its ascent by the hydrostatic pressure of the water on the reservoir outside the cylinder; and on the next descent of the piston the water will again pass through the valve *v*, and will be driven through the valve *x* on its next ascent. It is manifest from inspection that the valve *x* relieves the valve *v* from the pressure of the column of water in the tube CE during the descent of the piston; for if the valve *v* were subject to that pressure during the descent of the piston, it could not be opened by the pressure of the water in the well, inasmuch as its level is necessarily below the level of the water in the pipe CE. The valve *v* prevents the return of the water through the piston during its ascent. In raising the piston a force is required sufficient to support the entire column of water from the valve *v* to the surface of the water in the tube CE. To estimate this, we must take the weight of a column of water whose base is equal to the area of a section of the piston,

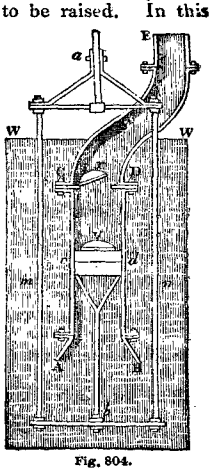

Fig. 804.

and whose height is equal to that of the surface of the water above the valve *v* in the tube CE. Hence, after each stroke of the pump, the pressure on the piston and the force necessary to raise it, will be increased by the weight of a column of water whose base is the horizontal section of the piston, and its height equal to the increase which the elevation of the column in CE receives from the water driven through the valve *x*. In the figure *cd* is the piston, the bottom of whose rod is at *b*; *m* and *n* are rods which connect it with the upper part of the work, and WW is the level of the water in the well.

2221. The common, or as it is usually called, *suction pump* (shown in *fig.* 805.), is nothing more than a large syringe connected with a tube whose lower extremity is plunged in the well from which the water is to be raised. The tube is called a *suction pipe* (SO), and its end in the well is represented at O, which, for the purpose of preventing the ascent of solid impurities, that might choke the pipe and impede its action, is pierced with holes like a strainer. At the upper end of this suction pipe is placed the valve *x* opening upwards. At this place the tube is connected with another, BC, which acts as a great syringe, and in which works a piston having a valve at *v*, also opening upwards. The piston is worked alternately upwards and downwards in common pumps by a lever called the *brake*, but it may be worked in many ways. In the figure, W is the level of the water, CD the *flange*, where the lower valve is fixed, *cd* the piston, *ab* the piston rod, and MN the cistern into which the water is raised and delivered by its gravity at the *nozzle* of the pump *e*. At the commencement of the operation the water in the suction tube stands at the same height as the water in the well, being equally subject to the atmospheric pressure; but as soon as the syringe BC exhausts the air by the upward and downward action of the piston *cd*, the pressure of the air in SO being diminished and rendered less than that on the surface of the water in the well, will rise in SO by the atmospheric pressure; and as the air becomes more completely exhausted in the column of water in the tube SO below the valve *x*, so will its pressure on the surface of the column be diminished, and whilst that diminution goes on, the height of the column will increase. If the air could be entirely withdrawn from the tube SO, and a perfect vacuum created beneath the valve *x*, similar to that existing above the mercury in a barometer, then the atmospheric pressure, acting with undiminished effect on the surface of water in the well, would, in the tube SO, sustain a column of water equal to a column of mercury of the same base and of the same height as the mercury in the barometer. Now, the specific gravity of mercury being 13½ times greater than that of water, a force capable of sustaining a column of mercury 30 inches high, would sustain a column of water equal to 30 inches × 13½ = 405 inches = 33 9/12 feet. But an absolute vacuum is never formed, and, moreover, in this country, as the barometric column varies between 28 and 31 inches in height, the valve *x* should on no account be more than 28 feet above the level of the water in the well, taking into consideration all the attendant circumstances.

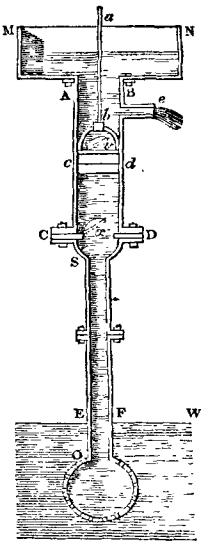

Fig. 805.

This is the construction and principle upon which the common household pump is formed, and in it no other aid is derived from atmospheric pressure than what we have already stated; hence the pump requires as much force to work it as, in general terms, is equal to the weight of all the water in it at any time, the atmospheric pressure affording no aid to the workman. The cistern at the top is placed for the purpose of affording an unintermitted discharge of the water by holding more than the whole accumulation of water which is contrived to be greater than the spout or nozzle will discharge.

2222. The *forcing pump* whose construction is shown in *fig.* 806., is a combination of the common suction and lifting pump. CEFD is a suction pipe descending into the well, and at its top is the valve V opening upwards. The pump barrel ABCD is furnished with a solid piston *cd*, whose rod is *ab*, without any valve. From the side of the barrel, just above the suction valve, a pipe proceeds, communicating with an upright cylinder GH, carried to such height as the water is intended to be raised. At the bottom of this cylinder is placed the valve V' opening upwards. At the commencement of working, the suction pipe CE and the chamber between the piston and valves are filled with air. When the piston descends to the valve V, the air enclosed in the latter chamber becomes condensed, and opening

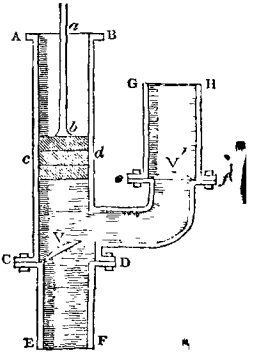

Fig. 806.

therefore, the valve V', a part of it escapes through it. On raising the piston the air below it becomes partially exhausted, and that in the suction pipe, opening the valve V by its greater pressure, expands into the upper chamber. A part of this is expelled when the piston next descends, by means of the valve V'. This action is similar to that of an air pump or exhausting syringe. When by the repetition of this action the air is sufficiently exhausted, the atmospheric pressure upon the water in the well causes the water to rise therefrom through the suction pipe and the valve V, into the chamber between the piston and the valves. When the piston next descends it presses on the surface of the water, and the valve V closing prevents the return of the water into the suction pipe, while the pressure of the piston being transmitted by the water to the valve V', opens it, and as the piston descends, the water passes into the force pipe GH. On the next ascent of the piston more water is allowed to pass through the valve V, and the next descent forces this water through the valve V' into the force pipe. By repeating the action the quantity of water in the force pipe increases, receiving equal additions at each descent of the piston. It is obvious that the position of the force pipe is a matter of no moment; it may be perpendicular, oblique, or horizontal; for in each case the water will be propelled through it. When the piston is pressed downwards, and the valve V' is opened, it is necessary that the force working the piston should balance the weight of the column of water in the force pipe, for this weight is transmitted by the water between the piston and force pipe to the bottom of the piston; the height, therefore, of the column of water in the force pipe will measure the intensity of the pressure against the base of the piston when the valve V is open. A column of water suspended 34 feet in height in the force pipe will press on the base of the piston with a force of about 15 pounds for each square inch; and the pressure at other heights will be proportional to this. Thus the force necessary to urge the piston downwards may always be calculated. The valve V' is closed in drawing up the piston, and it then relieves the piston from the weight of the incumbent column. If the valve V is opened, the piston is subject to the same pressure as in the suction pump, and this has already been seen to be equal to the weight of a column of water raised above the level of the water in the well. From this it follows, that when the height of the force pipe is equal to the length of the suction pipe, the piston will be pressed upwards and downwards with equal forces; but when the height of the force pipe is greater or less than the length of the suction pipe, the downward pressure must be greater or less, in the same proportion, than the force which draws the piston up.

2223. The supply of water by the force pipe through the valve V' is evidently intermitting, being suspended during the ascent of the piston; hence the flow from the point of discharge will be subject to the same intermission if means be not taken to counteract such effect. A cistern at the top of the force pipe, as already shown, for the suction pump, would answer the purpose; but it is found more convenient to use an apparatus called an *air vessel* (see *fig.* 807.), in which immediately above the valve V' a short tube communicates with a strong close vessel of sufficient capacity, through the top whereof the force pipe GH passes, and descends to near the bottom. When the pump is in action the water is forced into the vessel MN, and when its surface, as at *ww*, rises above the mouth H of the force pipe, the air in the vessel MN is confined above the water; and as the water is gradually forced in, the air, being compressed, acts with increased elastic force on the surface of the water. This pressure forces a column of water into the pipe HG, and maintains it at an elevation proportional to the elastic force of the condensed air. When the air in the vessel MN is reduced to half its original bulk it will act on the surface of the water *ww* with double the atmospheric pressure; meanwhile, the water in the force pipe being subject to merely once the atmospheric pressure, there is an unresisted force upwards equal to the atmospheric pressure which sustains the column of water in the tube, and a column 34 feet high will thus be sustained. If the air is reduced to one third of its original bulk, the height of the column sustained will be 68 feet, and so on. If the force pipe were made to terminate in a ball pierced with small holes so as to form a *jet d'eau*, the elastic pressure of the air on the surface would cause the water to spout from the holes.

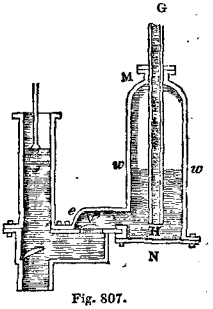

Fig. 807.

2223a. In the formation of all pumps the parts should be nicely fitted, and as air-tight as possible, otherwise, in using them, much of the power employed will be lost. All expedients which tend to this great desideratum are of value; indeed, any arrangement adapted to insure the perfect action of a pump is of the utmost importance for the comfort and convenience of small, no less than large, dwellings. The joint CD, *figs.* 805 and 806, is especially liable to leak if not well fitted. The variety of pumps now made is very great, although they are all formed on the principles first explained. The architect had best select the manufacturer, and learn of him the make and powers of his articles. Among

these inventions are: Pumping apparatus for public thoroughfares with cast iron cased well-engine frames, with fly wheel and with one or two handles; pillar well-engine frame and single or double cranks; the same with wheel and pinion to decrease labour; rotary action, fixed on plank; horse wheel frame, for horse power, and others applied to steam power; pumps for artesian wells; lift-pump; vibrating standard lift-pump; and rotary action lift-pump, all on planks; &c.

2223*b*. Another mode of obtaining a supply of water is by the *hydraulic ram*. It is more available in the country on account of the noise caused by the continual clicking of the valve. It is a simple self-acting machine for raising water into a cistern or tank where a fall of water can be secured from a stream, or other source. Once set in motion it will continue to work as long as it is supplied with water or until the wearing of the iron valve disables it. A fall of only 5 feet to the ram will enable it to supply a tank 60 feet higher than the source and 2,000 yards distant. Much of our present information on the subject of supply of water was known to the Romans, and is carefully described by Vitruvius in Book VIII. of his work.

2223*c*. Having obtained the source of a water-supply, a *tank* for a collection for a farm, or a *cistern* for the supply of a house, are requisite. The former may also be required to retain the rain water from the wood, lead, or zinc gutters of the buildings; water from copper gutters is poisonous. The *tank* is usually formed of brick or stone built in cement, and cemented inside, and when of a small size it is domed over, with a man-hole for access. If of large size, iron girders supporting slate or stone slabs will form a flat covering to it. These should be well jointed to prevent dirt falling in. Painting the cement with a solution of silicate of potash, is said to prevent the soft rain water becoming hard in a new tank. Such a system as the following would be found very serviceable on many farms having clay lands.

2223*d*. In Venice, the rain water is collected from the roofs and led into the court-yard, where it undergoes a regular system of filtration before it reaches the tank, whence it is raised by buckets. The construction to effect this consists of—I. A water-tight enclosure, II. A well of dry brickwork in the centre of, III. A wall of sand, filling up the remainder of the enclosure round the well, and serving partially as a reservoir, and partially as a filter; care being taken that no water enters the well but what passes through the sand. The system is shown in the *Allgemeine Bauzeitung* for 1836, pl. 556; and in the *Transactions* of the Institute of British Architects, 1842, p. 187.

2223*e*. Another and more simple method is described in the *Building News*, 1862, p. 127. A large hole is dug about 9 feet deep; the sides are supported by an oaken framework of a square truncated pyramid, the wide base being turned upward. A coating of compact clay, 1 foot thick, is applied on the frame with great care to stop the progress of the roots of plants, as also to prevent the pressure of the water. A large circular stone, partly hollowed out like the bottom of a kettle, is placed therein with the cavity upwards, and on this as a foundation a cylinder of well baked bricks is constructed having no insterstices except a number of holes in the bottom row. The large vacant space left between the sides of the pyramid and the cylinder is filled with well scoured sea sand. At the four corners of the pyramid a stone trough is placed covered with a stone lid pierced with holes; they communicate with each other by means of a small channel made of bricks resting on the sand, and the whole is then paved over. The rain water is led from the roof to these four sink stones, and penetrating into the sand through the channels, filters down and passes into the filter itself by the small hole left in the bottom row of bricks. These cisterns get filled five times a year, and the distribution of water is at the rate of about 312 gallons per head. The annual average rainfall is 31 inches.

2223*f*. The *cistern* for a house was originally placed outside, and made entirely of lead, the front of it being frequently decorated with devices, either cast with it, or secured by *paleing*, i.e., the soldering on of embossed figures. Lead cisterns are still in use, but they are cased with wood, and placed where most wanted for the supply. They should never be put where the sun can act upon them, as vegetation in the water sometimes ensues.

2223*g*. A cistern is usually made of $1\frac{1}{4}$ or 2 inch memel fir, lined with 6 lb. lead. A cover should always be provided. This metal lining is now much superseded by one of zinc, on account of the deleterious effects arising by the action of pure water on the lead; but zinc can only be trusted as a temporary resource. Slate is a better material for all collections of water or other liquids in general use. Care must be taken that a porous quality be not supplied; and it should not be placed where mild damp air will meet and condense on its cold surface, and consequently run down in drops. As it is so unyielding to the expansion of ice, its position in the house in that respect is an important consideration, and in case the joints become leaky from that or any other cause. Cisterns are supplied with water by a main service or feed pipe sufficiently large to allow of its filling during the time the water is turned on. The flow of water is regulated by a *ball cock*. The cistern to supply a water-closet should properly be distinct from that for domestic purposes; and when it is placed in a confined spot, necessitating smallness of dimensions, one of an

upright form is essential to provide the head of water for flushing the basin. *Fig.* 807*a.* shows an apparatus fitted to a lead cistern for supplying water to the pan. A, the ball valve pulled down by the wire B, and thus lifting by the wire C, the valve D, which admits the water into the lead service-box E, soldered into the bottom, F, of the cistern. The air-pipe G lets out the air from the box forced into it by the pressure of the water rushing through the down pipe, H. A waste pipe for emptying the cistern, or for carrying off the surplus water when being over filled, must always be provided When a cistern supplies the house, a service pipe is required from it, the outlet having a *rose*. For a slate cistern, a brass flange, (*fig.* 807*b.*) fitted with screws and nuts, is soldered to the lead service-box, and then secured to the slate. A "round closet valve with union fly-nut," and air-pipe (*fig.* 807*c.*) is occasionally used in lieu of the above contrivances; or a spindle valve with union, fly-nut and air pipe.

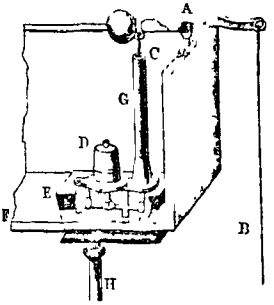

Fig. 807*a.*

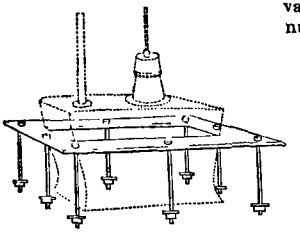

Fig. 807*b.*

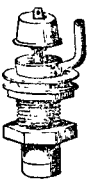

Fig. 807*c.*

2223*h.* Wrought iron tanks and cisterns made of plate iron riveted, plain or galvanized, are made to any shape or size; as also of a small size in stoneware. With the constant supply system now being introduced in many towns, service cisterns are said to be unnecessary; but it will be well to form one near any office requiring a good supply of water, as the house is occasionally cut off for a day or two from the mains, during repairs or cleaning. In some towns, the company insist upon a small cistern being placed in each water-closet, to prevent waste of water. The main service pipes may be of smaller bore than for the intermittent supply.

2223*i.* One cube foot of cistern will hold nearly 6¼ gallons of water; and a cube foot of water weighs 62·321 lbs.; a gallon weighs 10 lbs.; a cylinder inch, ·02842 lbs.; and a cylinder foot, 49·1 lbs. The supply for each man, woman, and child in a house is reckoned at 15 gallons per day, though it is considered no one really uses much more than 6 gallons; or about 12 gallons, as calculated by Sir W. Clay, by a family in London. An imperial gallon per man per day, appears to be the allowance on board a vessel. In stables, each horse should be provided with 16 gallons, four of which is consumed with his food. Each four-wheeled carriage takes about 16 gallons. Each two-wheeled carriage about 9 gallons. To wash a paved court or passage, a gallon of water may be provided for each superficial yard. The supply of water to London has been calculated at from 30 to 40 gallons per head, or about 150 gallons per house per day, for all purposes. The available rainfall from roofs in England is estimated at 18 inches per annum; and if the source of supply be only rainfall, a tank capable of holding 4 months' collection should be provided. (Hurst, *Surveyors' Handbook.*)

2223*k.* Filters are used for purifying water for towns, or purposes for which large quantities are required. They are usually formed in England of several layers of sand and gravel, gradually increasing in the volume of its particles in descending; and in the lowest course of gravel, perforated tiles are laid, through which the water flows into the reservoirs. The water is supplied on the top, so as to stand at a depth of from 4 to 6 feet over the sand and other filtering media. At the Lambeth Water Works, these media consist of: I. A layer of sand 3 feet thick; II. A layer of clean sea-shells 6 inches thick; III. Fine gravel 6 inches thick; IV. Coarser gravel 6 inches thick; V. Very coarse screened and washed ballast 6 inches thick; and VI. Pierced tiles covering the drains. At the Southwark Water Works the filtering media are rather thicker. At Hull the sand is 2 feet thick, and the gravel 16 inches thick. At York the sand is 4 feet thick, and the gravel 4 feet thick. At Paisley the sand is 2 feet thick, and the gravel only 6 inches; but the upper part of the sand is mixed with animal charcoal. Local conditions must regulate the proportion of these materials, for the thickness of the sand must be increased according to the impurity of the water. When the water is at all turbid, it is advisable to make settling reservoirs by the side of the filtering basins, to collect the impurities. The usual yield of filtered water from a basin established under the preceding conditions, is about 80 to 100 gallons per foot superficial per day.

2223*l.* In some places both the chemical and mechanical impurities may be eliminated from water by dividing the tank by a cross wall of a filtering stone. Such a stone will

filter about 60 gallons per foot superficial per day. Chemically, this could be effected by causing the water to pass through a diaphragm or cross wall, composed of two slabs of filtering stone, placed at a small distance from one another, and filled in with animal charcoal or with magnetic oxide of iron. The latter material appears to be the best for such water as is collected from roofs, because it parts with its oxygen with great rapidity to the rain water, and is susceptible of rapid revivification; it is also cheaper than charcoal. A double wall thus formed ought to pass 100 gallons per foot superficial per day. Ransome's patent siliceous stone is the best material of the kind ordinarily obtainable in England. Filters of porous sandstone, as made at Halifax, are recommended as effective and durable. A paper on the subject of filtration, read at the Institute of British Architects, 1850–51, by Mr. G. R. Burnell, and given in the *Builder*, ix. 404, deserves attention. Household filters, whether for occasional use or for a system of domestic filtration of water as it flows from the cistern, is now a serious subject of consideration for each tenant and landlord. A few drops of permanganate of potass, put into water tasting and smelling of decaying organic matter, will render it in a few minutes clear and sweet. A small quantity of alum tends to render water very pure, by freeing it from matters held in suspension.

2223*m*. From the cisterns *pipes* are required to convey the water to the several places it is destined to supply. Those of lead are either cast round, or soldered. In casting, a mould is made of brass, wherein down the middle a core of iron is loosely supported, at such a distance from the mould all round as is equal to the contemplated thickness of the pipe. When this is set, the core is removed and the cylinder opened, so as to withdraw the pipe, which is much thicker than is needed, and must be lengthened, while its substance is reduced, by *drawing* it through a succession of holes in steel plates, diminishing gradually in diameter, similarly to the method employed in drawing iron rods. This machinery became gradually improved in its construction, so that it was of rare occurrence to meet with an imperfect pipe. Lately, the manufacture of lead pipes has been further improved by casting them under hydraulic power. A quantity of lead is placed in a box, and forced through the mould at a certain rate, which gives the metal time to cool, so that it is pressed out gradually in a complete state, and wound round a wheel ready for use, its length being made within the limits of carriage. When pipes are made by soldering, a core of wood is provided, round which the sheet lead is rolled, and the edges are brought together and joined with *solder*.

2223*n*. The *pipes* used for the purposes of building are proportioned to their uses. Those, for instance, called *soil pipes*, for carrying away the soil from a water closet; or those for conveying water from roofs, called *water pipes*; and from sinks, are, of course, of larger diameter than those called *service pipes*, which are merely, as their name implies, for laying on water to a house, those of somewhat larger diameter being called *main service pipes*.

2½	10	-	70	7·0			86	8·6			100	10·0

2223*o*. *Solder* is a mixture of two parts of lead with one part of tin. In soldering, portions of the lead must first be scraped, and when finished they are then done over with a black paint. This solder is used also for tin plates and zinc work.

2223*p*. *Earthenware pipes*, like iron mains, are employed underground. At the beginning of this century, machinery was invented for forming *stone* pipes, which were used for some time, but did not supersede those in use formed of timber. Near Lincoln have been found circular earthenware tiles, 6 inches diameter and 22 inches long, set in a thick casing of cement, so as to exclude air entirely, and to strengthen and protect the piping, which conveyed the water for about a mile and a half. It is always necessary to have some outlets for letting off the air which accumulates in any length of such tubing. When water is first allowed to enter a long length of new piping, a quantity of very fine sand or dust should be put into it to fill up any cracks or spaces left in the joints. This is also recommended to be done for new iron boilers, iron water tanks, &c., as it tends to make the joints watertight. A well made stoneware pipe of 4 inches diameter will bear a pressure of from 75 to 100 lbs. per square inch.

2223*q*. *Iron water pipes* for the service of a house are objectionable in case of their bursting in winter, but this is remedied by placing a stop-cock at the entrance of the pipe into a house, to shut off the supply for repairs, or in anticipation of a frost. Some wrought iron pipes are lined and coated with hydraulic mortar; others are *enamelled* in the interior. These latter have been found, both for gas and water purposes, absolutely incorrodible; in the former case preventing the great loss from leakage, and in the latter case conveying the water in perfect purity. For a high service hot water supply, a galvanized wrought iron hot water cistern, with main hole screwed down, is supplied. It is usually 2 feet 6 inches long, 2 feet wide, and 18 inches deep. Cast iron pipes are naturally very porous; so much so, that water when very forcibly compressed as in an hydraulic machine, will make its way through the thick cast iron cylinder in a sort of perspiration on the external surface. Oxidation, to a certain extent, will close the pores of the metal, and prevent this escape of water or of gas; and it is recommended that all new gas pipes be proved with a solution of sal ammoniac, which being forced into the body of the metal effectually oxidizes it, and to a great extent cures the evil. Patent welded wrought iron tubes and fittings, and malleable iron fittings, are made for gas, or low pressure steam, and cast iron pipes for water, of from ⅛ to 4-inch bores; such pipes are also made for high pressure steam or water, and proved to a pressure of 200 lbs. per square inch. The ordinary gas pipe is proved to 75 lbs. on the square inch.

2223*r*. *Gutta Percha*. On account of the injurious effects of water on lead cisterns and piping, this material has been recommended as a substitute for it in both cases, since its general introduction about 1849. But it is uncertain whether the material can be guaranteed as a lining; and some soils appear to affect it when buried underground. It is also attacked by a fungus. Experiments made at the Birmingham Water Works, on the strength of gutta percha, showed, that tubes made ¾ inch diameter and ⅛ inch thick, attached to the iron main, and subjected for two months to a pressure of 200 feet head of water, were not in the slightest degree deteriorated. They were afterwards subjected to a proof of 337 lbs. per square inch. The material being slightly elastic, the tubes expanded, but recovered their former size on the pressure being withdrawn. At Stirling, 1½ inch tubing bore a pressure of about 450 feet, without the slightest injury, whilst the same pressure upon strong leather hose scattered the rivets in all directions.

2223*s*. Pipes to cisterns are supplied with ball cocks and valves, both round way and square way, of various forms and sizes, too numerous to be here described. For sinks, or the usual supply taps, bib-cocks having a "T key" or a "spanner" or other key, are required; these are of different makes, and produce a recoil. "Screw-down" or "valves"

are used where the high pressure system is adopted, the "T key" then screws down the valve. A "stop-cock" or "valve" shuts off the water in a length of pipe, and is serviceable in shutting off the service from the main pipes, as above noticed, and for reducing the pressure of the water on the "screw-down" valves in a constant service. This system is described in Cresy, *Encyclopædia*, pages 1655–57.

2223*t*. *Lavatories* are fitted up with an apparatus for supplying the basin with hot and cold, and for taking off the waste waters. *Baths* are supplied from a boiler either placed at the back of a kitchen range, or set in the fireplace of the bath room, or of an adjoining chamber. They are also heated by a gas boiler adjoining the bath, having a flow and return pipe; or by ranges of lights under the bath itself. A five-feet bath is said to be heated to 100° in half-an-hour by gas, at a small cost. A bath generally contains about 60 gallons of water, and requires about 20 gallons of boiling water to heat it.

2223*u*. The bath itself is sometimes formed of marble, cast iron enamelled, opalized glass, glazed earthenware, and glazed porcelain tiles (Rufford's), the weight of which is 7 cwt.; while zinc, lead, copper, galvanized iron, and slate (par. 2211*p*.) all require a coating of light coloured paint, so as to render easily apparent any want of purity of the water. If not painted, all metal baths require considerable friction to appear clean. The difficulty of making a bath with joints that shall not leak is self-evident. Tylor's pattern-book gives several descriptions of their baths (par. 2288*a*).

2223*v*. With water raised to a high level great power is gained for various purposes, domestic and otherwise. The *hydraulic lift*, lately introduced into banks and hotels, is the saving of much trouble and time. The general details for hotels have been described by J. Whichcord, in a paper read at the Institute of British Architects, 18th January, 1864, and given in the *Transactions*. A small lift, to be worked by hand, is readily arranged for raising a scuttle of coals, or other package, from the bottom to the top of a building. Water applied to a turbine is capable of producing a small motive power, useful for organ blowing, turning a fan to effect ventilation, and other such purposes, without wasting the water so employed.

2223*w*. It will be useful to note the *non-compressibility of water*. It is often necessary, before re-melting cast iron, to reduce the large masses into smaller pieces. This by the ordinary method is both troublesome and difficult. A simple and ingenious mode of producing the required fracture has been recently employed in France. It consists in drilling a hole in the mass of cast iron for about one-third of its thickness, and filling the hole with water, then closing it with a steel plug, fitting very accurately, and letting the ram of a pile-driver fall on the plug. The first blow separates the cast iron into two pieces.

COPPER.

2224. Many of the uses to which copper is put have already been noticed in the paragraphs 1787 to 1791. The nave of Chartres Cathedral was roofed in 1836–41 with iron ribs covered with copper plates; in 1853 the latter had so much oxidised as to require removal. It is said that if strips of the best zinc, about 8 inches by 2 inches, be screwed on each course of copper, galvanic action would prevent the oxidation of the latter material. Iron cramps encased and brazed in copper, or gun metal cramps, in lieu of iron merely, the exfoliation of which bursts and demolishes stonework, is a precaution now generally adopted in good work. In the Indies, copper gutters decay after twenty years' use, not lasting longer than shingles; the heat and moisture of the climate converting the metal into red oxide of copper: iron nails decay there very fast from the same cause.

2224*a*. TABLE I. OF THICKNESS OF COPPER SHEETS.

Number of wire gauge	1	2	3	4	5	6	7	8	9	10
Weight of one foot super. in pounds	14·5	13·9	12·75	11·6	10·1	9·4	8·7	7·9	7·2	6·5

The table given in Hurst's *Handbook*, page 82, is a slight increase on the above; from that work, page 85, the following table has been derived.

2224*c*. TABLE III. OF THE WEIGHT OF COPPER, PER SUPERFICIAL FOOT, IN POUNDS.

Thickness	$\frac{1}{16}$	$\frac{1}{8}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$	$\frac{3}{8}$	$\frac{7}{16}$	$\frac{1}{2}$
Weight	2·891	5·781	8·672	11·563	14·453	17·344	20·234	23·125

Thickness	$\frac{9}{16}$	$\frac{5}{8}$	$\frac{11}{16}$	$\frac{3}{4}$	$\frac{13}{16}$	$\frac{7}{8}$	$\frac{15}{16}$	1
Weight	26·016	28·906	31·797	34·688	37·578	40·469	43·359	46·250

2224*d*. Solder for copper, iron, and brass, is composed of an alloy of zinc and copper; pewter, for an alloy of tin, lead, and bismuth.

2224*e*. *Wetterstedt's patent metal* should be laid by a good plumber. The flats are formed with rolls and drips similar in every respect to lead, but the latter should be formed with a gradual descent. The rolls need not be more than 1 to 1$\frac{1}{4}$ inch diameter, tapered at the ends, and brought close up to the edge of the drip. Circular and sloping roofs may be laid either with rolls or welts, the ends of the sheets being joined by a welt or overlap of 6 inches. The metal should be laid free, and nails avoided as much as possible, but if used they should be of wrought copper. Soldering is to be avoided, but to secure the metal as against an upright face, a solder dot over a screw is the best means to adopt.

2224*f*. *Muntz's metal* is used as a coating for iron vessels under water; to prevent galvanic action a band of vitreous sheathing is attached for some distance below and above the water line. This sheathing consists of small plates of iron covered with a preparation of glass, and is intended to be an anti-fouling as well as a protective agent.

ZINC.

2224*g*. The common sheets in general use are 12, 14, 16, 18, and 20 ounces to the foot superficial; and as 18 thicknesses of 16 ounces to the foot are half an inch thick, the following show the thicknesses of the different weights:—

Plates or sheets of 10 ounces to the foot are 0·01736 inch thick.
" 12 — 0·02083 "
14 — 0·02430 "
16 — 0·02777 " = $\frac{1}{36}$ of an inch.
18 — 0·03125 "
20 — 0·03472 "

It is employed for water-cisterns and baths, rain-water pipes—in short, for almost all purposes where lead has been hitherto employed. Latterly it has been formed into sash-bars for skylights, and ornamental sashes; for which purposes, strength excepted, it is superior to iron, as not being liable to rust, and loosen the putty and glass. It is, in every respect, equal to copper, and not more than one-third the cost of it. The discovery of the electro process was said to have introduced the application of zinc to cast and wrought iron, so as to prevent its oxidation or rust, but such has not been the case (see galvanized and zinked IRON).

2224*h*. About 1861, the Vieille Montagne Zinc Mining Company took steps to improve the mode of laying zinc roofs, and to prevent the use of thin gauges of sheet zinc, which are unfit for the purpose. This Company recommend that for roofs and flats on boards no gauge thinner than No. 13 be used; a medium thickness, No. 14, for roofs, flats, and gutters; for best work and for roofs without boards, Nos. 15 or 16. The Company is preparing thicker zinc, Nos. 17 and 18, principally for gutters. Steel cut gauges notched for roofing numbers only, are supplied whereby to test the thickness. The weight of No. 13 gauge is 19 oz. 10 drs.; No. 14 is 21 oz. 13 drs; No. 15 is 24 oz.; and No. 16 is 26 oz. 3 drs., per square foot.

2224*i*. Good zinc, properly laid, has been proved by long experience in France, Belgium, Germany, and Italy, to be a secure, durable, and economical covering. No detrimental effects from any particular climate are to be feared, so that care be taken to adopt the proper mode of laying, and to select the proper gauges, of the best quality of zinc. Even good zinc badly laid will prove a failure. Screws or embossed holes on the surface of good zinc work are not required. As the prescribed mode for laying zinc, illustrated by diagrams, can be obtained on application to the agents of Devaux's Vieille Montagne Zinc Company, and to the agents for the supply of the Improved roofing zinc, we do not consider it necessary to describe it here in detail.

2224*k*. *Stamped ornamental zinc*, for dormers, Mansard roofs, vanes, finials, moulding, and enrichments, has been used on the Continent for many years with good effect. In London it is hardly known, but has been employed lately at the Charing Cross Hotel; at the Langham Hotel; and at No. 114 Piccadilly. The steeple of Ripple Church, Kent; the Victoria Railway Station, Pimlico; and many other public and private buildings throughout the kingdom, now show the employment of this useful material.

2224*l*. *Perforated zinc* for various sizes of perforations or in patterns, is extensively employed in filling up squares in sashes, or panels in partitions, to assist ventilation by breaking the force of the current of air.

Sect. VIII.

GLAZING.

2225. Glazing, or the business of the glazier, consists in fitting glass in sashes, frames, and casements, either in putty or lead. It may be classed under the heads of SASHWORK, LEADWORK, and FRETWORK. Glass, as a material, has been already described in Chap. II. Sect. XII. of this Book.

2226. The tools necessary for SASHWORK are—a *diamond*, polished to a cutting point, and set in brass in an iron socket, to receive a wooden handle, by which it is held in a cutting direction. The top of the handle goes between the root of the forefinger and middle finger, and the under part between the point of the forefinger and thumb. In general, there is a notch on the side of the socket, which should be held next the lath. Some diamonds have more *cuts* than one. Plough diamonds have a square nut on the end of the socket next the glass, which, on running the nut square on the side of the lath, keeps it in the cutting direction. Glass benders have their plough diamonds without long handles, as they cannot make use of a lath in cutting, but direct them by the point of their middle finger. The *ranging lath* should be long enough to extend beyond the boundary of the table of glass. *Ranging* of glass is the cutting it in breadths, and is best done by one uninterrupted cut from one end to the other. A *short lath* is used for stripping the square to suit the rebate of the sash, as in ranging they are generally cut full. A *square*, for the more accurate cutting at the right angles from the range. The carpenter's *chisel* is used in paring away some of the rebate of the sash when the glass does not lie so flat as to allow a proper breadth for front putty. The *glazing knife* is used for laying in the putty on the rebates, for bedding in the glass, and finishing the front putty. A *bradding hammer* is made with a head in the form of a small parallelopiped, with a socket for the handle, using it at an obtuse angle from the middle of one of its sides. The square edges of the head drive

the brads in a horizontal direction, and with this tool there is less liability to accident than with any other. Some use the basil of the chisel for the purpose. *Brass points* are considered the best for bradding; *small cut brads* are also used. All new work should be bradded, to prevent the glass being moved out of its bed. The *duster* is a large brush for brushing the putties, and taking the oil from the glass. The *sash tool* is used wet, for taking the oil from the inside after the back putties are cleared off. The *hacking knife* is for cleaning out the old putty from the rebates where squares are to be stopped in. The use of the *glazier's rule* needs no explanation: it is 2 feet long, doubling in four different pieces.

2226*a*. The *putty* in which the glazier beds the glass is of four sorts. *Soft putty*, which is composed of flour, whiting, and raw linseed oil; *hard putty*, composed of whiting and boiled linseed oil; *harder putty*, the same ingredients as the last, with the addition of a small quantity of turpentine for more quickly drying it; *hardest putty*, composed of oil, red or white lead, and sand. The first of these putties is the most durable, because it forms an oleaginous coat on the surface, but it requires a long time for drying. The hard sorts are apt to crack if not soon well painted, and the hardest of them renders it difficult to replace a pane when broken; hence it is altogether unfit for hothouse and greenhouse work. (See 2227*a*.).

2226*b*. To remove glass from old sashes, a mixture of 3 parts of American potash with 1 part of unslaked lime, laid on both sides with a stick, and allowed to remain for twenty-four hours, will soften the putty enough to cut out easily. This mixture will also take off paint, and even tar.

2227. LEADWORK for fixed lights is used in ecclesiastical buildings, often in inferior offices, and frequently in country buildings. Frames made with crossbars receive these lights, which are fastened to *saddle bars*. Where openings are wanted, a casement is introduced of wood or iron. Sometimes a sliding frame is used, particularly for house windows.

2227*a*. Probably the best manner of fixing glass and glazed frames in stone mullions, is with a mixture of Bath stone dust and linseed oil, made up similarly to putty. Its elasticity allows of any slight settlement if the work be new, and it is more of a waterproof cement than Portland, as it is not nearly so liable to crack: that cement, without a large proportion of sand, will almost invariably burst glass or stone after a few months; and it also stains freestones, Corsham Down stone especially, giving it the appearance of having been burnt. (*Builder*, 1864, p. 796.)

2228. The *glazier's vice* is for preparing the leaden slips called *cames* with grooves, &c., to fit them for the reception of glass. The German vices are the best, and turn out a variety of lead in different sizes. There are *moulds* belonging to these vices in which bars of lead are cast; in this form the mill receives them, and turns them out with two sides parallel to each other, and about $\frac{3}{8}$ of an inch broad, and a partition connecting the two sides together, about $\frac{1}{8}$ of an inch wide, forming on each side a groove near $\frac{3}{16}$ by $\frac{1}{8}$ of an inch, and 6 feet long. The *setting board* is that on which the ridge of the light is worked, and divided into squares, and struck out with a chalk line, or drawn with a lath, which serve to guide the workman. One side and end is squared with a projecting bead or fillet. The *latterkin* is a piece of hard wood pointed, and so formed as to clear the groove of the lead, and widen it, for the more readily receiving the glass. The *setting knife* is a blade with a round end, loaded with lead at the bottom of the blade, and having a long square handle. The square end of the handle serves to force the squares home tight in the lead; being loaded with lead, it is of greater weight, and also cuts off the ends of the lead with greater ease, as in the course of working these lights the lead is always longer than is necessary till trimmed.

2229. The resin box contains powdered resin, which is put on all the joints previous to soldering. *Clips* are for holding the irons. All the intersections are soldered on both sides except the outside joints of the outer side, that is, where they come to the outer edge. These lights should be cemented, which is done by thin paint being run along the lead bars and the chasm filled with dry whiting. After it has stood a short time a small quantity of dry red or white lead is dusted over it, which will enable it to resist the weather well.

2229*a*. FRETWORK is the ornamental part of lead-light work, and consists in working ground or stained glass into different patterns and devices, as may be seen in the old stained glass windows. The leads used until the middle of the seventeenth century, are nearly of one uniform width, and are much narrower in the *leaf* than the common modern leads. That this was the case, can be proved not only by the existence of the original leads themselves, but more satisfactorily perhaps by the black lines drawn upon the glass, with which the glass painters were accustomed sometimes to produce the effect of leads without unnecessarily cutting

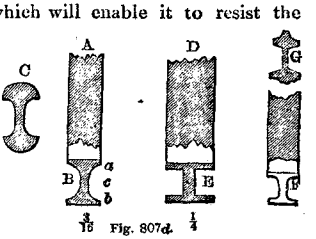

Fig. 807*d*.

the glass. A in *fig.* 807*d.* represents an ancient lead of the usual width; B its section, consisting of the *leaf*, *a* and *b*, and the *core* *c*. C is the section of a German lead of the early part of the 14th century. D is a piece of modern *fret lead* of the ordinary width, and which is now considered (1847) as being very narrow; and E its section. The process of compressing the lead between rollers to the proper dimension makes them more rigid than the old leads. It is the practice at the present day to surround each *glazing panel* with a *broad lead*, that is, a lead three-quarters of an inch broad in the leaf, to strengthen the work (page 27.). Leads somewhat narrower than these were very extensively employed. An entire window, at Stowting Church, Kent, probably of the early part of the reign of Edward IV., was leaded with leads as F. The other lead, G, is of the early part of the reign of Henry VI., and is from Mells Church, Somersetshire, where similar lead is commonly used. This mode of strengthening the lead without increasing its width was not confined to the decorated period. Both these specimens had all the appearance of being cast in a mould. One of the faces in each is narrower than the others; these were placed outside, and the difference probably arose from decomposition of the metal. A still narrower lead may be occasionally met with in heraldry and other minute mosaic work of the 15th and 16th centuries. It is hardly necessary to observe that the greater the number of leads employed, the weaker individually may they be made (page 259–61.). The width of the leads must be proportionate to that of the lines usually painted on the glass, for the leaden outlines will easily be detected if they are much stronger than the painted ones. The effect of the increased width of modern leads, E, although so trifling, is very perceptible.

2229*b*. *Saddle bars* in ancient windows will be found to be usually placed from 8 to 9 inches apart, which seems to be the most agreeable distance, though one of 6 inches does not appear too little in some cases. The great object is to avoid, as much as possible, causing the light to appear as if it were divided into a number of square compartments, by making the height too nearly the width of the glass. Amongst the advantages resulting from the use of saddle bars at short intervals, is the opportunity it affords the glazier of carrying a horizontal lead across the light immediately in front of each saddle bar, the opacity of which hides the lead. This method of concealing lead work was carried to such perfection during the first half of the 16th century, that a person ignorant of it would find it difficult to conceive how some of the works of that period were constructed.

2229*c*. *Iron standards* or *stancheons*, in ancient windows put through the saddle bars, should be retained in pattern windows, which they improve, and do not appear to be out of place in picture windows whenever they do not happen to pass immediately behind the head of the principal figure. They seem also on the whole to improve the effect of the architecture from without. (Winston, *Inquiry into Style in Glass Painting*, 8vo. 1847.)

2229*d*. It is stated that at Cologne Cathedral the glass is strong; the different pieces are joined together with lead, and soldered with tin, both inside and outside, which gives the whole great strength. The panes are fastened upon iron frames, which are again fastened upon rods. In the interior the panes are screwed upon iron bars, half an inch thick, which are let into the masonry.

2230. In London a large portion of the glazier's business consists in cleaning windows.

2231. *Glazed partitions* formed of wood, or of iron frames with the lower panels filled in with slate, are now very usual in warehouses, banks, and counting-houses. If sound be desired not to pass through such fittings, they must be glazed with extra thick glass; but double sheets or squares, placed about half an inch or more apart, and carefully puttied, is best. This method will also conduce to the warmth of the room. Double windows to the fronts of houses are common fittings to effect both the above purposes.

2231*a*. Glass has been introduced for a variety of building purposes. Thus, Lloyd and Summerfield's patent crystal *window bars*, for windows, shop fronts, and cases, are not uncommon. They are fitted with arched heads and spandrils of glass, having patterns, silvered or gilt, on a coloured ground. Glass *tiles* and *slates* are a useful auxiliary to a roof where a small modicum of light is required. Lockhead's *perforated glass ventilator* can either be set in the sash, or fixed outside of it in a frame for the whole width of the opening, air being admitted by moving the sash. For the like purpose are such inventions as Moore's louvre ventilators in a sash pane; Boyle's draughtless window ventilators, being a fine gauze of wire set in a pane of glass, and used with or without a glass cover; and the glass revolving ventilator. Glass *balusters* and *handrails*; pilasters for chimney-pieces; door handles, knobs, and plates; mirror frames; trays for dairies; and cut crystal and opal letters, are among the other useful inventions in this material.

2231*b*. *Coloured or stained glass*. We can only here name the varieties. There are three modes of colouring glass: I. Pot metal glass, in which the colour is mixed up with the molten mass. II. Flashed, covered, or coated, glass, formed by uniting a thin layer of coloured glass with another layer, either of a different colour or colourless. III. Painted glass, the white substance being painted on, and then the colour or pigment burnt in. The colouring materials are in all cases metallic substances. Such are the methods by which all coloured glass windows are produced.

2231*c*. For ornamental purposes, besides *coloured* glass, glass may have a *ground* surface, which is obtained by grinding it with a stone, or by the use of fluoric acid. *Embossed glass*, which permits the application of devices, according to the fancy of the designer or intention of the manufacturer, is effected by covering the square of glass with a varnish, except where the device is intended. An acid is then poured on which eats away the uncovered glass for a small depth. The varnish is then cleaned off, and the general surface is ground as usual. Its imitation is obtained by covering the plate with a varnish, a lace or stencil pattern placed on it, then dusted over with a colouring matter in the state of fine powder, and the plate thus treated sufficiently heated to vitrify and fix the dusted varnish to the glass. Messrs. Chance, and other manufacturers, sell various enamelled stencilled patterns, as *white enamelled, enamelled and flocked, embossed repeated pattern, stained enamelled,* and *double etched glass, self shadowed glass, patent polychromatic glass, printed glass, stamped in colours*, and many other kinds, all which are better seen at the factories than described.

2231*d*. The compressive strength of glass, that is, its resistance to a force tending to crush it, is about 12¼ tons per square inch. This is nearly equal to one quarter the strength of cast iron. Glass has three times the specific gravity of iron. In the form of bars, a favourable shape for developing a highly tensile strength, one ton per square inch of area is the highest amount to be assumed for it.

2231*e*. MOSAIC WORK. This durable manner of decoration in glass, requires a short notice. The *Roman mosaic* is composed of pieces of enamelled glass, thus rendered opaque, sometimes called *smalto* and sometimes *paste*, made of all kinds of colours and of every different hue. For large pictures they take the form of small cakes. For small works they are produced as threads, varying in thickness from that of a piece of string to the finest cotton thread. The *Venetian mosaic* pictures are formed of pieces of very irregular shapes and sizes, of all colours and tones of colours; the ground tint almost invariably prevailing is gold. The manner of execution is always large and coarse, and rarely approaches any neatness of joint or regularity of bedding. *Opus Grecanicum* consists in the insertion, into grooves cut in white marble to a depth of about half an inch, of small cubes of these coloured and gilded *smalto*, and in the arrangement of these forms in such *geometrical combination* as to compose the most elaborate patterns. It was customary to combine the bands of this mosaic work with large slabs of Serpentine, Porphyry, Pavonazzetto, and other valuable marbles, and to use it in the decoration of ambones, cancelli, &c.; its use externally was comparatively rare. The hexagon, triangle, square, and octagon, form the usual bases of most of the specimens of this ingenious art to be found in Italy. Patterns of accumulating intricacy are seen at Palermo, and at Monreale. Illustrations in colour are given in the useful work on *Mosaics*, by M. D. Wyatt.

2231*f*. *Coloured enamels* are made of a vitreous *paste* (or glass), to this are added other mineral substances, which, when properly prepared and fused together, impart to the paste its density and extreme hardness, and also its colour; the better the manufacture, the more satisfactory the appearance and the greater the durability of the mosaic work. In an imperfect manufacture, the mosaic is liable to be injured by damp, smoke, and all atmospheric changes; when well produced, they can be made to give precisely the same effect as the painting.

2231*g*. *Gold and silver enamels* were introduced: these are made of the precious metals, but in such thin sheets that their use is comparatively inexpensive. The process is a difficult one, for, to produce true gold and silver enamels, great knowledge and experience are necessary. On a ground of thick glass or enamel, according as it is desired to render the gold enamel transparent or opaque, or to impart to it a warm or variegated colour, there is laid a leaf of gold or silver, which is attached principally by the action of fire; then a film of the purest glass is spread over it, and this may either be perfectly colourless or of any tint that may be required. When well manufactured, these thin layers, after being fused, become perfectly united with each other, and form a homogeneous body, and the metal is for ever protected against all possibility of injury from any cause except actual violence.

2231*h*. Stevens has produced a new kind of glass mosaic, executed at about one third the price of the ancient manufacture of this kind. The glass is stained or gilt, and the method is adapted for many purposes. Messrs. Rust are working in gold, silver, and enamel mosaics of their own invention; and Dr. Salviati employs his "indestructible system of Venetian enamel-mosaic, in works, in a comparatively inexpensive and expeditious manner." At the Wolsey tomb-house, at Windsor, the entire ceiling, consisting of 2,100 feet, was decorated in the space of ten months, including the time of the transit of the mosaics from Venice; and was executed, with the scaffolding, at the price of 4,725*l*. It was also employed at St. Paul's Cathedral, for the figure of the prophet Isaiah, covering 250 feet, which was executed and fixed in two months, at the price of 600*l*. (Lecture read at Leeds, by A. Salviati, 1865.)

2231*i*. The cements used are of three sorts. The first, for large tesseræ in forming floors, is composed of pitch, mixed with a black earth. The second, for stones of a mid-

dling dimension, is made of tufa and oil. The third, for the more delicate mosaics of pieces of glass, is made of white of lime, pounded bricks, gum andragan, and the white of eggs. The ancients are said to have used 1 part of slaked lime and 3 parts of pounded marble, made up with water and white of egg. But as this is considered to harden too quickly, a mixture of 1 part of slaked lime, and 3 parts of powdered travertine stone, mixed up with linseed oil, and kept stirred every day, is used, adding oil as it dries. The mass is ready sooner in warm weather than in cold, varying from 20 to 30 days, when it is like a smooth ointment. For the larger works, Keene's, Portland, or other similar cements might be used.

Sect. IX.

PLASTERING.

2232. In the finishing of our dwellings, the decoration owes much of its effect to the labours of the plasterer: it is in his department to lay the ceilings, and to give, by means of plaster, a smooth coat to the walls, so as to hide the irregularities left by the bricklayer and mason, and make them sightly and agreeable. He also, in the better sort of buildings, furnishes plain and decorated mouldings for the cornices and ceilings; and in the external parts, where stone is expensive or not to be procured, covers the exterior walls with stucco or other composition imitative of stone.

2233. The plasterer's tools are—a *spade* or *shovel* of the usual description; a *rake* with two or three prongs bent downwards from the line of the handle, for mixing the hair and mortar together; *stopping* and *picking out tools*; rules called *straight edges*; *wood models*; and *trowels* of two sorts and various sizes, namely, the *laying and smoothing tools*, consisting of flat pieces of hardened iron, about 10 inches long, and 2½ inches wide, very thin, and ground to a semicircular shape at one end, but square at the other. Near the square end on the back of the plate a small iron rod is rivetted, with two legs, whereof one is fixed to the plate, and a round wooden handle is adapted to the other. All the first coats of plastering are laid on with this tool, as is also the last, or *setting*, as it is technically called. The other sorts of trowels are of three or more sizes, and are used for *gauging* the *fine stuff* and plaster for cornices, mouldings, &c. The length of these trowels is, the largest about 7 inches in length on the plate, and the smallest 2 or 3 inches: they are of polished steel, converging gradually to a point, with handles of mahogany adapted to the heel or broad end with a deep brass ferrule.

2234. The stopping and picking out tools are of polished steel, of various sizes, about 7 or 8 inches long and half an inch broad, flattened at both ends, and somewhat rounded. They are used for modelling and finishing mitres and returns to cornices, as also for filling up and finishing ornaments at their joinings. There is also used a small instrument which is a piece of thin fir 6 or 7 inches square, called a *hawk*, with a handle vertical to it for holding small quantities of plaster.

2235. The composition used by the plasterer is a groundwork of lime and hair, on which, for the finish, a coating of finer material is laid. The sorts of it are various; as for instance, white lime and hair mortar on bare walls; the same on laths as for partitions and plain ceilings; for renewing the insides of walls, roughcasting on laths; plastering on brickwork with finishing mortar, in imitation of stone work, and the like upon laths. For cornices and the decorations of mouldings, the material is plaster of Paris, one which facilitates the giving by casts the required form and finish to the superior parts of his work. The plasterer uses it also for mixing with lime and hair, where the work is required to dry and set hard in a short time. For inside work, the lime and hair, or *coarse stuff*, is prepared, like common mortar, with sand; but in the mixing, hair of the bullock, obtained from the tanners' yards, is added to it, and worked in with the rake, so as to distribute it over the mass as equally as possible.

2236. What is called *fine stuff* is made of pure lime, slaked with a small quantity of water, and afterwards, without the addition of any other material, saturated with water and in a semi-fluid state placed in a tub to remain until the water has evaporated. In some cases, for better binding the work, a small quantity of hair is worked into the composition. For interior work, the fine stuff is mixed with one part of very fine washed sand to three parts of fine stuff, and is then used for *trowelled* or *bastard stucco*, which makes a proper surface for receiving painting.

2237. What is called *gauge stuff* is composed of fine stuff and plaster of Paris, in proportions according to the rapidity with which the work is wanted to be finished. A four-fifths of fine stuff to one of the last is sufficient, if time can be allowed for the set. This composition is chiefly used for cornices and mouldings, run with a wooden mould. We may here mention that it is of the utmost importance, in plasterers' work, that the lime should be most thoroughly slaked, or the consequence will be blisters thrown out upon the work after it is finished. Many plasterers keep their stuffs a considera-

period before they are wanted to be used in the building, by which the chance of blistering is much lessened.

2238. When a wall is to be plastered, it is called *rendering*; in other cases the first operation, as in ceilings, partitions, &c., is *lathing*, nailing the laths to the joists, quarters, or battens. If the laths are oaken, wrought iron nails must be used for nailing them, but cast iron nails may be employed if the laths are of fir. The lath is made in three and four foot lengths, and, according to its thickness, is called *single*, something less than a quarter of an inch thick, *lath and half*, or *double*. The first is the thinnest and cheapest, the second is about one-third thicker than the single lath, and the double lath is twice the thickness. When the plasterer laths ceilings, both lengths of laths should be used, by which, in nailing, he will have the opportunity of breaking the joints, which will not only help in improving the general *key*, (or plastering insinuated behind the lath, which spreads there beyond the distance that the laths are apart,) but will strengthen the ceiling generally. The thinnest laths may be used in partitions, because in a vertical position the strain of the plaster upon them is not so great; but for ceilings the strongest laths should be employed. In lathing, the ends of the laths should not be lapped upon each other where they terminate upon a quarter or batten, which is often done to save a row of nails and the trouble of cutting them, for such a practice leaves only a quarter of an inch for the thickness of the plaster; and if the laths are very crooked, which is frequently the case, sufficient space will not be left to straighten the plaster.

2239. After lathing, the next operation is *laying*, more commonly called *plastering*. It is the first coat on laths, when the plaster has two coats or set work, and is not scratched with the scratcher, but the surface is roughed by sweeping it with a broom. On brickwork it is also the first coat, and is called rendering. The mere laying or rendering is the most economical sort of plastering, and does for inferior rooms or cottages.

2240. What is called *pricking up* is the first coat of three-coat work upon laths. The material used for it is coarse stuff, being only the preparation for a more perfect kind of work. After the coat is laid on, it is scored in diagonal directions with a *scratcher* (the end of a lath), to give it a key or tie for the coat that is to follow it.

2241. *Lath layed* or *plastered and set* is only two-coat work, as mentioned under laying, the setting being the guage or mixture of putty and plaster, or, in common work, of fine stuff, with which, when very dry, a little sand is used; and here it may be as well to mention, that *setting* may be either a second coat upon laying or rendering, or a third coat upon *floating*, which will be hereafter described. The term finishing is applied to the third coat when of stucco, but setting for paper. The setting is spread with the smoothing trowel, which the workman uses with his right hand, while in his left he uses a large flat-formed brush of hog's bristles. As he lays on the putty or set with the trowel, he draws the brush, full of water, backwards and forwards over its surface, thus producing a tolerably fair face for the work.

2242. Work which consists of three coats is called *floated*: it takes its name from an instrument called a *float*, which is an implement or rule moved in every direction on the plaster while it is soft, for giving a perfectly plane surface to the second coat of work. Floats are of three sorts: the *hand float*, which is a short rule, that a man by himself may use; the *quirk float*, which is used on or in angles; and the *Derby*, which is of such a length as to require two men to use it. Previous to floating, which is, in fact, the operation of making the surface of the work a perfect plane, such surface is subdivided in several bays, which are formed by vertical styles of plastering, (three, four, five, or even ten feet apart,) formed with great accuracy by means of the plumb rule, all in the same plane. These styles are called *screeds*, and being carefully set out to the coat that is applied between them, the plaster or floating laid on between them is brought to the proper surface by working the float up and down on the screeds, so as to bring the surface all to the same plane, which operation is termed *filling out*, and is applicable as well to ceilings as to walls. This branch of plastering requires the best sort of workmen, and great care in the execution.

2243. *Bastard stucco* is of three coats, the first whereof is roughing in or rendering, the second is floating, as in trowelled stucco, which will be next described; but the finishing coat contains a small quantity of hair behind the sand. This work is not hand-floated, and the trowelling is done with less labour than what is denominated trowelled stucco.

2244. *Trowelled stucco*, which is the best sort of plastering for the reception of paint, is formed on a floated coat of work, and such floating should be as dry as possible before the stucco is applied. In the last process, the plasterer uses the hand float, which is made of a piece of half-inch deal, about nine inches long and three inches wide, planed smooth, with its lower edges a little rounded off, and having a handle on the upper surface. The ground to be stuccoed being made as smooth as possible, the stucco is spread upon it to the extent of four or five feet square, and, moistening it continually with a brush as he proceeds, the workman trowels its surface with the float, alternately sprinkling and rubbing the face of the stucco, till the whole is reduced to a fine even surface. Thus, by small portions at a

time, he proceeds till the whole is completed. The water applied to it has the effect of hardening the face of the stucco, which, when finished, becomes as smooth as glass.

2245. From what has been said, the reader will perceive that mere laying or plastering on laths, or rendering on walls, is the most common kind of work, and consists of one coat only; that adding to this a setting coat, it is brought to a better surface, and is two-coat work; and that three-coat work undergoes the intermediate process of floating, between the rendering or pricking up and the setting.

2245*a*. This plain plastered surface has received an improvement in a method of stamping or incising it, while wet, the invention, in 1857, of Mr. Benj. Ferrey, architect. "It is well known that the external rough-casting on old timber houses was stamped or wrought in small devices, known by the term *pargetting*; but it never assumed the importance of extensive wall decorations. The plan now proposed is to impress the common stucco with geometrical or other forms, and applied according to taste, either under string courses, around arches, in spandrils, soffites, or in large masses of diapering; and texts may be imprinted on the plaster instead of being simply painted on the walls. If colour be desired, it can be effected by mixing the desired colour with the coat forming the groundwork, then by laying the stencilled pattern against it, and filling in the solid portions of the device with the ordinary stucco or plaster." The process does not pretend to do more than enliven wall surfaces, but for this purpose it is very effective. Whippingham Church, in the Isle of Wight, is decorated in this manner, with devices in different colours.

2246. Ceilings are *set* in two different ways; the best work is where the setting coat is composed of plaster and lime putty, commonly called *gauge stuff* (2237). Common ceilings are formed with plaster without hair, as in the finishing coat for walls set for paper. The deflection of $\frac{1}{20}$th of an inch for each foot in length is not injurious to ceilings; indeed, the usual allowance for settlement is about twice that quantity. Ceilings have been found to settle about four times as much without causing cracks, and have been raised back again without injury. (Barlow, p. 179.)

2246*a*. In Dublin, the designations in plasterers' work are different to those we have named above. Work to ceilings is described as "Lath scratched, floated, and coated; while to walls it is described as "scratched, floated, and coated." *Skimming*, to plasterers work, is a very thin coat of white (i.e. lime) put on float work to smoothen it, and to leave a clean face; *coated* is the term for better work of the same character.

2246*b*. *Wirework*, in place of *lathing*, for forming ceilings and other plaster surfaces, patented in 1841 by L. Leconte, had been previously adopted in the building of the Pantechnicon, near Belgrave Square.

2246*c*. Nickson and Waddingham have patented a *slate ground for plaster*, by using, instead of laths, those slates which do not turn out in the quarries sufficiently wide for sized roofing slates; an immense number of them being necessarily thrown aside daily, although of the best quality. The slates are fixed with the rough side towards the plaster, and $\frac{1}{4}$ in. apart; the plaster to be $\frac{3}{4}$ in. thick, of well haired stuff, which keys itself between the slates and into perforations, two or more being made in each slate according to its size; they run from 12 to 17 in. long and upwards. The system has been worked for about four years at Manchester, and has many other useful qualities.

2247. *Pugging* is plaster laid on boards, fitted in between the joists of a floor to prevent the passage of sound between two stories, and is executed with a coarse stuff made of lime and hay chopped into lengths of about 2 inches.

2248. The following materials are required for 100 yards of render set; viz. $1\frac{1}{2}$ hundred of lime, 1 double load of river sand, and 4 bushels of hair; for the labour, 1 plasterer 3 days, 1 labourer 3 days, 1 boy 3 days; and upon this, 20 per cent. profit is usually allowed. For 130 yards of lath plaster and set—1 load of laths, 10,000 nails, $2\frac{1}{2}$ hundred of lime, $1\frac{1}{2}$ double load of river sand, 7 bushels of hair; for the labour, 1 plasterer 6 days, 1 labourer 6 days, 1 boy 6 days; and upon this, as before, 20 per cent. is usually allowed.

	inch	$\frac{7}{8}$	$\frac{3}{4}$ in.	$\frac{5}{8}$	$\frac{1}{2}$ in.
1 bushel of Portland or Roman cement will cover, yards super.	$1\frac{1}{2}$	$1\frac{3}{4}$	$1\frac{1}{2}$	$2\frac{1}{2}$	$2\frac{1}{2}$
1 ditto, and 1 of sand	$2\frac{1}{4}$	$2\frac{3}{4}$	3	4	$4\frac{1}{2}$
1 ditto, and 2 ditto	$3\frac{1}{4}$	$4\frac{1}{4}$	$4\frac{1}{2}$	6	$6\frac{3}{4}$
1 ditto, and 3 ditto	$4\frac{1}{2}$	$5\frac{1}{2}$	6	8	9
1 cwt. of mastic and 1 gallon of oil			$1\frac{1}{2}$		$2\frac{1}{2}$

1 cubic yard of chalk lime, 2 yards of sand, and 3 bushels of hair, will cover 75 y of render set on brickwork; 70 yards on lath; or 65 yards plaster; or render two c and set on brick; and 60 yards on lath. Floated work requires about the same as t coats and set. A bundle of laths and 500 nails will cover about $4\frac{1}{2}$ yards superfic Two hundred laths, 4 feet long, are required for a square. A bundle of laths contains feet nominally.

2249. In the country, for the exterior coating of dwellings and out-buildings, a sp of plastering is used called *roughcast*. It is cheaper than stucco or Parker's cement,

therefore suitable to such purposes. In the process of executing it, the wall is first pricked up with a coat of lime and hair, on which, when tolerably well set, a second coat is laid on of the same materials as the first, but as smooth as possible. As fast as the workman finishes this surface, another follows him with a pailful of the roughcast, with which he bespatters the new plastering, so that the whole dries together. The roughcast is a composition of small gravel, finely washed, to free it from all earthy particles, and mixed with pure lime and water in a state of semi-fluid consistency. It is thrown from the pail upon the wall, with a wooden float, about 5 or 6 inches long, and as many wide, formed of half-inch deal, and fitted with a round deal handle. With this tool, while the plasterer throws on the roughcast with his right hand, in his left he holds a common whitewasher's brush dipped in the roughcast, with which he brushes and colours the mortar and the roughcast already spread, to give them, when finished, an uniform colour and appearance.

2249*a*. *Gypsum* or *plaster of Paris* is largely used in France for the construction of walls, both internally and externally, as well as for rendering them afterwards. We adopt the following method of working it, as explained by G. R. Burnell: "The coarser kinds of plaster are used for rendering; the finer qualities for ceilings, cornices, and decorative works. For walls, the plaster must be gauged stiff for the first coats, and more fluid for the setting coat. For cornices worked out in the solid, the core is made of stiffly gauged plaster, which is floated with finer material, and lastly finished off with plaster laid on by hand, about the consistence of cream. Practice only can ascertain the precise degree of stiffness to be given, as every burning yields a different quality of plaster. When walls are to be rendered, they require to be first jointed, and then wetted with a broom. The surface is then covered with a coat of thinly gauged stuff, laid on with a broom, or at least worked with a trowel in such a manner as to leave sufficient hold for the next coat. This is gauged stiff, and is laid on with a trowel; it is floated with a rule, but the face is finished with a hand trowel; the surfaces, however, are never so even, or the angles so square and true, as in the usual plasterers' work adopted in England. The ceilings are lathed about 3 to 3½ inches from centre to centre, and the plaster poured in from above on to a sort of flat centering, leaving about an inch for the thickness of plaster; the ceiling coat is added after the centering is removed. The better descriptions are made with laths 4 inches from centre to centre, the space between ceiling and floor filled up with light work, and the under and upper surfaces rendered to receive the ceiling and tiles."

2249*b*. With gypsum, only about ⅓ths of the evaporation arises as from ordinary plastering. A series of experiments made in 1850, proved that the cost of ordinary works need not exceed in any sensible proportion, if at all, those usually called "render set;" and that they are strictly the same as "render float and set." A room was begun and finished in thirty hours, whilst a common lime and hair rendering coat would have required, properly speaking, about a month. French plaster must never be used in any position where moisture is likely to affect it for any length of time. It is very hygrometric, and soon decays if kept moist. If it be used as mortar, as in brick-nogged partitions, to be covered over immediately, a space for its expansion must be allowed. In France, a small space is left between the wall and partitions; this is filled in by the plastering coat. The same observation applies to floors with plaster pugging, and even to cornices with a large body of that material, the mitres and returns being executed some time after the straight mouldings.

2250. In forming the coves and cornices which are applied below the ceilings of rooms, it is of the greatest importance to make them as light as possible, for the plaster whereof they are formed is heavy, and ought not to depend merely on its adhesion to the vertical and horizontal surfaces to which it is attached. Hence, when cornices run of large dimensions, bracketing, as has already been described in the section JOINERY (2079, *et seq.*) must be provided, of the general form of the cornice or cove, or other work, and on this the plastering is to be formed. On this, when roughed out, the work is run with wooden moulds, having zinc or copper edges, so as to give the general outline of the cornice. If enrichments are used in it, they are cast in plaster of Paris, and afterwards fixed with that material in the spaces left for them to occupy. These enrichments are previously modelled, and from the model a matrix is formed, as for all other plaster casting. Great nicety is required in all the operations relative to the moulding and fixing of cornices, and most especially that the ornaments be firmly fixed by screws or other means, that they may not be detached from their places by partial settlements of the building, and cause accidents to the occupiers of the rooms where they are used.

2250*a*. In 1862 Mr. Westmacott patented a new plaster, made by combining lime with unburnt limestone or chalk, suitably ground or reduced to powder. When using very good lime, 2 measures of unburnt chalk or limestone to 1 of lime can be taken as the proportion. This compound may be employed alone, or combined with sand, plaster of Paris, clay, or other materials, according to the circumstances under which it is to be used. Some experiments were made on this plaster by a Committee of the Institute of British

Architects, in 1863. The quick stucco for rendering ceilings consisted of 2 parts of unslaked lime to 1 of chalk, with sand, mixed together before adding the water; it occupied twenty minutes in making and setting, and was followed in an hour by ordinary gauged stuff, and stood without cracking. For outside work, the proportions to be used are 1 part of slaked grey lime to 2 of chalk, used as cement or common mortar. This is to be treated like lime, and therefore must be used directly. The difference between this and the internal or quick stucco, is that the latter material has been dry slaked before being gauged. When placed on the wall, it hardens and sets at once throughout its mass; whilst the other, slaked like mortar, hardens gradually from the surface. When required for common mortar, the lime is slaked, and ground chalk mixed with it to form a cream; then sand is added in the usual manner. This is used at once, but it will improve with age if kept damp; it indurates gradually, varying, according to the weather and amount of sand it contains, from a sixteenth to an eighth of an inch per week. For rendering plaster, the sand may be mixed with the lime and chalk before adding water, the difference being that whereas in the first form the mortar gradually indurates, in this it can be placed upon the laths before the lime slacks, which generally takes place in an hour, and it often sufficiently hardens to be followed by the second coat in the same day. It does not eventually indurate to an equal strength with the first method, yet it forms a plaster harder and stronger, without hair, than is generally obtained with that material combined. It is not liable to crack. An external stucco, in which a highly hydraulic lime is used, is formed of one part of lime, two of chalk, and two of sand; this stucco indurates quickly through the mass. A specimen of seven months old, and formed of 1 part of grey lime and 2 parts of chalk, which had been placed for that period exposed to atmospheric influences, showed great hardness. This plaster will take a good polish in about three minutes. By the addition of a little plaster of Paris, a good internal cement is produced, which dries quickly, and is much harder than plaster of Paris.

2250*b*. A *rendering plaster* for superseding the use of lime and hair mortar in the plastering of walls and ceilings, has been brought forward by A. G. Barham, of Bridgwater. It is stated to be very tough and strong, not liable to crack or swell, and is applied without hair, direct to brick walls or lathwork. The surface dries and hardens rapidly, and it can be painted or papered at once, as there is nothing in the plaster to injure either of the processes. When dry it is of itself a good grey in colour. For outside stucco, it is also stated to be a safe material, and is likewise free from vegetation and colouring.

2250*c*. Stucco is a species of plastering which is sometimes subsequently worked to resemble marble. There are two sorts of *stucco*, those made of limes, and those made of plaster. The former are often classed under the name of cements, but their disagreeable colour prevents their being used for ornamental decoration. They serve, however, to form the foundations for the better class whenever humidity is to be feared. The latter are generally made of lime, mixed with calcareous powder, chalk, plaster, and other substances, in such a manner as to obtain in a short time a solid surface, which may be coloured, painted, and polished with such perfection as to allow of its being used instead of more expensive materials.

2250*d*. The Italians usually execute their stuccos in three coats; the first is very coarse, to form the rendering. The second is much finer, and contains a larger proportion of lime, bringing the work up to a very even close grain. The last is made of rich lime, which has been slaked and run through a very fine sieve; it is allowed to stand from four to five months, in order that every particle may be reduced to a hydrate. If the lime cannot be kept for so great a length of time, the slaking may be assisted by beating it up very frequently. When great perfection is required, pounded white Carrara marble is mingled with it; gypsum and alabaster are used for enclosed situations. Colours are obtained by mixing with the lime such metallic oxides, &c., as the case may require. The excellence of the work consists in the care with which the effects of the natural marbles are imitated.

2250*e*. When plaster is used instead of lime, it is gauged with lukewarm water, in which size or gum has been dissolved, so as to fill up the pores, to give more consistency, and to render it susceptible of receiving a better polish. Any colours used should be previously dissolved in the size water. When the whole of the stucco is perfectly dry, the surface is then rubbed with grit stone and polished up with rubbers much in the same way as real marble. The thickness of a coat of stucco varies from one-sixth to one-eighth of an inch.

2250*f*. *Stucco work*, as it is called, and as executed daily in Ireland for outside work, consists of their *roche lime*, slaked for three or four months previously, as above described, mixed with sand, and worked up with the trowel. It stands the weather as perfectly as Roman cement. The term is also given to the interior moulded and cast work.

2250*g*. The manufacture of *Scagliola* work, an imitation of real marbles, is described in the Glossary. It has generally been assumed as a mystery. We shall, in this place, only notice some of its uses. Scagliola is so easily put up in a building, and requires so small an amount of time and expense for renovation and repair, compared with repainting and

varnishing, that those who are induced to go to the expense of plastering the walls with mastic, to be ready for immediate painting, marbling, and high polishing, might be justified in expending a further sum and adopt scagliola at once. For the walls of the staircase in the building formerly called Crockford's Club House, St. James's Street, the scagliola was prepared upon slabs of slate half an inch thick, sawn on the surface with cuts about one-eighth of an inch deep, to form a key for the plaster groundwork. When the slabs were fit for polishing they were secured with battens fixed to the wall. The scagliola to the staircases at the Reform Club House is worked upon the walls; they are richly panelled, moulded and inlaid. The fluted columns, in the same building, to the gallery and skylight of the saloon are done upon stone. The three-quarter columns in the drawing and coffee rooms were cast in three lengths, and each backed with tiles bedded in coarse plaster. Some black and gold columns, worked in Keene's cement on stone, and two twisted columns in plaster, are placed in Wilton Church, Wiltshire. When Parian cement is used, the groundwork is formed of wet cement of the coarse quality, the veneer being of the same thickness as common scagliola; but one half of the quantity of colours will produce the same depth of colouring as in the common scagliola. For polishing, the same process is to be followed as for walls, as described in par. 2251*i*.

2250*h*. Scagliola *floors* exist at Sion House, Isleworth; at the entrance hall at the Athenæum Club House, London; and at Crewe Hall, Cheshire. Many other examples of the employment of scagliola work will be found named in an excellent article in the *Builder* for 1863, p. 840, one of the best on the subject; and another in February 1845. A very inferior imitation of scagliola is too often to be seen.

2250*i*. A material has been lately prepared at the Patent Marble Works, for similar purposes. It is manufactured in slabs from $\frac{3}{4}$ to 1 inch thick, of any size, for lining, and for moulded work. The prices are stated to be under those of enamelled slate. *Marezzo marble*, made of cement, has been introduced since 1868. The entrance hall at the Society of Arts, London, has been lined with it.

2251. In the present time, the use of ornaments made of *carton-pierre*, a species of *papier maché*, has been reintroduced for cornices, flowers, and other decorations. The basis of it is paper reduced to a pulp, which, having other ingredients mixed with it, is pressed into moulds, and thus ornaments are formed of it. They have not all the delicacy of the plaster cast, and there is the want of that nicety which a good cornice workman in plaster exhibits; but their lightness, and the security with which they can be fixed with screws, render them often preferable to plaster ornaments. The "Critic" newspaper in 1863 stated that in Bergen, in Prussia, there is a church capable of holding 1,000 persons, constructed entirely, statues and all, of papier maché. Probably, however, the material is that used to a very great extent in Norway and Sweden for forming the roofs of houses, and said to be incombustible. It appears to be in many respects similar to the *Fibrous slab*, the manufacture of which, by Bielefeld, was discontinued a few years since, after much success; though the dust penetrated through it, showing the marks of the joists, as in plaster work. The ceiling of the reading room at the British Museum was lined with it. Another material, superseding *carton-pierre* and papier maché, is Desachy's *Fibrous plaster*, which is formed of a thin coat of plaster of Paris, run upon a backing of coarse canvas. It is of great lightness, not inflammable, and is ready to be painted immediately after it is made. It is adapted for the speedy and economical production of any coffered or circular work; and for wagon-headed ceilings, as but little bracketing is necessary, it being fixed to the joists direct; for fluted or ornamented columns, panelled dadoes, &c., for the lining of walls and ceilings, and for all purposes of ornamental plaster work. Mr. Owen Jones has extensively used this material for his interior decorations.

CEMENTS.

2251*a*. We have already adverted to the cements used in plastering. Parker's, Atkinson's, and Portland, cements, are the principal ones for the outside coating of buildings, and the process of laying them on is so similar to that of other plasterer's work, that it will not be necessary to say much respecting them. The best mode, perhaps, of using these natural cements is to employ them purely in works under water, or where a great crushing weight is to be brought upon them at once. For foundations in damp situations, where rapidity of execution is desired, the mixture may be 2 parts of sand to 3 of cement; and also for cornices or coatings exposed to the weather. For upright faces, the proportion is of 3 parts of sand to 1 of cement. Care must be taken that no fissures are formed such as will admit water, as the action of frost will destroy it. The brickwork in mortar, to be covered, should be thoroughly dry, or the expansion of the water will throw off the cement; the brickwork itself must, however, be wetted before a coat is applied, to prevent the absorption of the moisture before the coat sets, or it will not harden. With slow setting cements, it is too often the custom to allow the filling out, and even plain faces, to become partially set, when the adhesion of the next quantity will be found imperfect and unsound.

All work requires to be finished off at once for a good result. Dirty sand causes the cement to be crumbly. Cement once set, or even partially so, should not be worked up in a fresh mixture, or it will form rotten work. Like lime in the setting coat in plastering, cement facings and mouldings are not so liable to show fire-cracks on the face if a small quantity of sand be mixed up with it.

2251*b*. In using *Portland cement*, plasterers should use thicker screeds, and finish their work in one coat with the screed-rule, instead of working all the water used in gauging to the surface with the hand-float and trowel, spoiling the thinner coat whilst they lay it on. This cement has an advantage over others, that it can, with good management, be worked in winter, while other cements cannot be so used without great risk of the frost injuring them before they are dry. More cement added to make a coat set quicker, causes it to crack and burst. This cement is best when used of a uniform thickness of $\frac{3}{4}$ths of an inch, any dubbing out being done with pieces of brick and Roman cement. A proportion of Portland cement mixed in the usual plastering coat affords a quicker drying material for finishing with Portland or with Martin's cement. The coarse quality of Martin's cement takes the place of plastering, and all the delays consequent on its use.

2251*c*. However much we may regret employing cements to cover the coarse brick and rubble stone of our buildings, it must be acknowledged that they are in a far better condition than many of those in which the stones, commonly used during late years, have been introduced.

2251*d*. For *interior* embellishments, the cements known as Martin's, Keene's, and Parian, are largely adopted. *Martin's cement* is manufactured in three qualities, coarse fine, and superfine. The coarse quality presents a whitish speckled surface, and is supplied in red, light red, and grey, colours. The fine is whiter; the superfine is a cream colour. It is said to cover 20 per cent. more surface, at half an inch in thickness, at a less cost than an equal quantity of any other cement for internal use, and to be 35 per cent. cheaper than such cements. For walls, 1 part of coarse cement is used with $1\frac{1}{2}$ of clean dry sharp sand, for the under coat of half an inch thick, finished with $\frac{1}{8}$ inch thick of pure cement. It is of a fireproof character, and preserves to some extent the building from damp: the cement is supposed to continue to indurate with age, and therefore to be very durable. When adopted for floors, skirtings, and other finishings, whether plain or ornamental, in lieu of wood, the cost is stated to be less than similar work executed in that material, while in appearance it is very much superior, as it takes a fine polish. It can be painted upon within twenty hours after having been worked on old brickwork, and in twelve hours when on lathed work; but all three qualities are as well without paint. Plaster of Paris must not be mixed with it, or Roman or Portland cement used as an undercoat.

2251*e*. *Keene's cement* is said to show on its face the lines of any woodwork which it may be carried across. If required, it can be painted upon in twenty-four hours after the coat on old brickwork is completed. Skirtings, flooring, and internal stucco are worked in this material, on account of its superior hardness. This cement will mix with any of the metallic oxides, &c., to produce a coloured cement.

2251*f*. *Parian cement* (Keating's patent), for internal stucco, has been used throughout the Westminster palace. It does not effloresce, takes paint or paper in forty-eight hours, and makes a very hard and beautiful scagliola. It sets in four or five hours. It must not be treated as common plastering, by being hand-floated up with water, as for all purposes as little water as possible is to be used with it. This material must not come in contact with green lime, or with limewater in any of the operations. On *brickwork*, it is first floated about $\frac{1}{2}$ in. thick, with equal parts of clean washed sharp sand, and the surface slightly dragged. The next day a setting coat, $\frac{3}{16}$ in. thick, of net cement, may be worked, laid down with a beech float and slightly trowelled. If intended to be painted or papered, the first coat of paint should be applied from twenty to twenty-four hours after. The paint is to be mixed, for the first coat, only one-fourth oil and three-fourths turpentine, and with a very small portion of red lead and gold size. The succeeding coats of paint are to be mixed in the usual manner. On *lathing*, the laths may be closer than usual; the first coat of equal parts of clean washed sharp sand and cement, broomed while soft, and floated the next day with cement as before; the setting coat to be followed up next day, and finished as described for brickwork. The three coats will be $\frac{3}{4}$ in. in thickness.

2251*g*. *Damp walls* require a first coat of Portland cement $\frac{3}{4}$ in. thick; when dry, a coat of $\frac{1}{2}$ part of Parian cement mixed with $\frac{1}{4}$ part of washed sand, gauged very stiff, rubbed in hard, and dragged before it sets. When hard, a floating coat without sand is to be applied; to be set as before on the following day, and painted on the succeeding morning, without fail.

2251*h*. For *floors*, the cement mixed with $\frac{1}{3}$ part of Bath stone dust, $\frac{3}{8}$ in. thick, is to be laid on a solid bottom of Portland concrete, in one body $\frac{3}{4}$ in. thick. On *common plastering*, where the ordinary time is allowed for finishing the works, the plaster is to be laid fair, and dragged and left to dry; the cement to be mixed with an equal part of washed sharp sand and floated $\frac{1}{2}$ in. thick. The next day a thin coat of cement having $\frac{1}{8}$ of sand is laid down and trowelled as before. If required to be *papered*, it must first have two coats of

paint. In patching, when required to be painted or distempered on immediately, the edge of the old plastering is to have first a coat of paint.

2251*i*. For *polished work* on walls, the floating coat is mixed with equal parts of sharp sand and cement. The setting coat is $\frac{1}{4}$ in. in thickness, of fine net cement, rubbed down with grit stones and water; the grit is to be then well washed off, and when the water is gone, a stopping of fine cement mixed up stiff in a pan is to be applied and well rubbed in. This is then to be scraped off with a wood scraper, and the stopping repeated until a proper face is obtained, leaving a scum on the face to be taken off by the next grinding, which should be done with finer grit stones. The stopping is to be repeated and finally finished with snake stone, putty powder, and clean cloths. Three or four weeks' time is required before a good polish can be obtained, it being essential that each successive stopping of fine cement should be allowed several days to harden before the surface is again scraped.

2251*k*. For *casting* work, the cement is to be mixed stiff and dubbed in the moulds with a brush, and then left until thoroughly set. Such are the instructions for all these several processes issued by Messrs. Francis, the manufacturers of this cement, which was applied to the walls of the wards, corridors, and staircases of Middlesex Hospital, in 1849, from its non-absorbing qualities.

2251*l*. A very good specimen of plain decorative work is to be seen in the booking-office of the London, Chatham, and Dover Railway Company, at the Victoria Station. The walls, piers, &c., were executed in this cement, then painted in flat tints, and var nished and polished several times.

2251*m*. Cement *floors* may be made in an economical manner, by first forming a bed of concrete to prevent damp rising, then placing on it a coat $1\frac{1}{2}$ in. thick of Atkinson's cement, mixed with three of clean fine sand; or in Roman cement; or in Portland cement, with four of sand, floated in by a rule on screeds, care being taken to prevent the joints setting. If the cement set slow, it may be trowelled down while soft, but not when it is setting, or the face will be injured. If the cement sets very quick, a rough key is to be formed, and then covered with fine mortar $\frac{1}{8}$ in. thick, trowelling it gently before it begins to set. If rising damps be not anticipated, the floor may be first paved with clean hard brickbats in lieu of concrete, and covered an inch thick with good cement.

2251*n*. Portland cement floors have answered perfectly in several instances, but it is an uncertain material; therefore, where the floors were not to be covered, or where a slight defect was of consequence, it has been considered better to use other cements, such as Keene's, as employed at the Metropolitan Convalescent Asylum, Walton-on-Thames. A good floor for common purposes is made of a concrete formed of 6 parts of clean gravel to 1 of ground lias lime: this is generally impervious to damp and vermin.

2251*o*. The *bituminous cements* are used for paving, and for covering the extrados of arches to prevent the percolation of water through them. In all new constructions, there are always movements which crack the coatings executed in limes and natural cements, which are also subject to unequal shrinkage, producing crevices; and from these united causes, it is very rare to find such coatings impermeable. The bituminous cements are more elastic; it may happen that small crevices, so to speak, solder themselves, and if any serious repairs are required they are much easier to be executed than in those works executed with limes. When asphalte is to be used, it is placed in a quantity of nearly boiling *mineral pitch* to secure its melting. Colonel Émy found the following proportions as the best for the asphalte of Gaugeac, and it may be taken for the others of this class of cements, when used as a coating for arches:—

$2\frac{1}{8}$ pints (wine measure) of pure mineral pitch.
11 lbs. avoirdupois of bitumen or asphalte.
17 pints of powdered stone dust, wood ashes, or minion.

It is advisable to lay this mixture upon a bed of concrete or mortar; and as much as possible in slabs of 2 feet 6 inches to 3 feet in width. It should be evenly spread and compressed with a trowel, well rubbed, and reduced to a uniform close surface. When all the bubbles have been expelled, a fine sand is sprinkled over the surface, and worked in with the trowel, observing never to fill the crevices formed by the air-bubbles with sand, but only with asphalte. The thickness for coating any arches is not more than from three-fifths to half-an-inch. The quantity of cement thus employed to cover a yard square is about $4\frac{1}{2}$ lbs.

2252. It is scarcely within the branch of the plasterer's practice, but as we shall have no other place for adverting to it, we may as well here mention what are called "composition" ornaments, seldom used in cornices, but principally for the decoration of chimney-glasses, frames, and to woodwork generally. The composition is very strong when dry, of a brownish colour, consisting of about 2 pounds of powdered whiting, 1 pound of glue in solution, and half a pound of linseed oil mixed together in a copper, heated and stirred with a spatula till the whole is incorporated. After heating it is laid upon a stone covered with powdered whiting, and beaten to a tough and firm consistence, when it is laid by for use, covered with wet cloths to keep it fresh. This composition is then put into moulds and pressed. Later inventions have nearly caused its disuse in architectural decoration.

Sect. X.

SMITHERY AND IRONMONGERY.

2253. Smithery is the art of uniting several lumps of iron into one lump or mass, and forming them into any desired shape. The operations necessary for this are primarily performed in the forge, and on the anvil with the hammer; but for finishing, many other implements and tools are necessary. These, however, we do not think useful to particularise, a course we have pursued in the other trades, because the expedients introduced by the engineer and machinist have of late years, except in rough work, superseded many of them. It is now, for instance, easier to plane iron to a perfect surface than it was a few years ago to file or hammer to what was then always an imperfect one. Formerly a man would be occupied as many minutes in drilling a hole as by machines it now takes seconds to perform.

2254. We have, in a previous section, given all the particulars relating to the produce of the metal from the ore; in this section we propose little more than to enumerate the different objects which the smith and ironmonger furnish in the construction of buildings; and introductory to that it will be convenient to subjoin tables of the weights of round and bar iron, and also of the weights of 1 foot of close hammered bar iron of different thicknesses; remembering that a cube foot of close hammered iron weighs about 495 lbs., of common wrought iron about 480 lbs., and of cast iron 450 lbs., whence may be derived the weight of other solids whose cubic contents are known.

Table showing the Weight of one Foot in length of a square Iron Bar.

	If of Cast Iron.							
12	4·835	9·664	14·500	19·336	24·172	29·000	33·836	38·672

2255. For the carcass of a building the articles furnished by the SMITH are, wrought iron *columns with caps and bases* for the support of great superincumbent weights; cast iron *columns* and *stancheons* are now preferred both for economy and stiffness; as was also that material for *girders, beams, joists,* and *bressummers,* until the introduction of *plate iron* and *rolled iron*; all which have been treated in previous sections. *Cast, blister, shear,* and *spring steel*; *charcoal sheets* and *plates*; *boiler, tank,* and *flitch plates*; *galvanized* and *tinned sheets*; *chequered floor plates, buckled plates*; *flat bars* up to 12 in. wide, *round bars* up to 8 in. diameter, *square bars* up to 5 in.; *angle,* T, and *trough irons. Ties* of all descriptions, *straps, bolts, nuts* and *screws, plates, washers,* and the like, employed in connecting pieces in framing where the strain is greater than the mere fibres of the wood will resist. *Half-round, bevelled, oval, octagon, hexagon, moulding,* and *fancy irons*; *hoop iron, nail rods,* and *sash iron*; *shoes* for piles, when that mode of obtaining a foundation is adopted; *cramps* for holding blocks of stone together, but those of cast iron are better, as less likely to be subject to oxidation; while those of copper or gun metal are still better; *area gratings* and *window bars* for securing openings, now generally superseded for those of cast iron, especially when of an ornamental character, as are *balusters* and *railings* for stairs and balconies; and, among other things, *chimney bars,* which are wide, thin, bent bars or plates of wrought iron (see SPECIFICATIONS), to relieve the weight of brickwork over a chimney opening; in kitchens and rooms where a large opening is required, and two bars may not be sufficiently strong, a wrought or cast iron *cradling* is necessary. The liability to expansion and contraction from the varying temperature often produces fractures about the chimney jambs, but on the whole they produce a security which sanctions their use. The Metropolitan Building Act requires that, if the breast project more than 4½ in. from the face of the wall, and the jamb on either side is of less width than 17½ in., the abutments must be tied in by an iron bar or bars, turned up and down at the ends, and built into the jambs for at least 8½ in. on each side.

2255*a*. The advantage of now being able to procure *wrought iron flitches* of a good

length and depth has obviated the necessity of *welding* two or more lengths together by the sledge hammer, which has not a sufficient impetus to reach the very core of the metal, and thus the joint became weaker than the remainder of the flitch or bar. In 1864 experiments were made at Paris, on the effect of welding by hydraulic pressure; two bars, each 1½ in. square, were thus welded together with great ease, and the machine was stopped when the part welded was brought down to the thickness of the bar. After cooling, the welded part was cut through, and the inside was found perfectly compact.

2255*b*. *Boiler plate* is made of rolled or wrought iron. They are termed *sheets* when under ¼ inch in thickness; *plates* from a ¼ inch to 2 inches thick; and *slabs* when more than 2 inches thick. They are named according to the quality of the iron, or the locality where they are manufactured. The sizes of those most in use are from 6 feet to 9 feet long, 2 feet to 4 feet wide, and from a ¼ to ¾ of an inch in thickness.

2255*c*. *Corrugated iron* is sheet iron which has been rolled into the form of a series of waves. It is in that state frequently used for a covering for temporary purposes; between joists to carry concrete, &c.; and for fencing, the corrugation giving a thin sheet great capability for carrying a heavy weight, or for stiffening framework. The flutes are generally about 5½ or 6 inches from centre to centre. Sheets of Nos. 16, 18 and 20 wire gauge are made from 6 feet by 2 feet, to 8 feet by 3 feet; and of Nos. 22, 24 and 26, from 6 feet by 2 feet, to 7 feet by 2 feet 6 inches. In calculating the measure for fixed roofing, add ⅒ to the weight per square for lapping. The sheets should overlap each other about 6 inches, and be double riveted at the joints. About 3lbs. of rivets are required for a square of roofing. In roofs, the iron sheets are best used in a curved form.

2255*d*. *Wrought iron casements* are still introduced into buildings; this has given rise to several improvements upon the old method of manufacture for making them wind and water tight. Those now generally advertised are, the patent *wrought iron windows*, by the General Iron Foundry Company (Limited); Burt and Potts' patent *wrought iron water-tight window and frame*; Gibbons and White's *wrought iron weather-tight casements and frames* for stone mullions; and casements for wood mullions, as designed by Mr. G. Devey, architect. All these are fitted with *casement stays and fastenings*. Connected with this purpose are Smith's (of Princes Street, Leicester Square) "patent weather-tight *water-bar*," for French casements, formed in the sill; and one of another make, by a manufacturer of the same name (formerly of Queen Street, Oxford Street).

2255*e*. The usual dimensions, outside of frames, of fire proof wrought iron doors and frames, and gates, may be usefully inserted here:—5 ft. 9 in. high by 2 ft. 3 in. wide; 6 ft. by 2 ft. 4 in.; 6 ft. 2 in. by 2 ft. 6 in.; 6 ft. 6 in. by 2 ft. 6 in.; 6 ft. 2 in. by 2 ft. 8 in.; and 6 ft. 4. in. by 3 ft.

2255*f*. Iron *shop fronts* are introduced in many towns. They are made from 12 feet by 6 feet to 14 feet by 10 feet, generally at one shilling per superficial foot. "White brass" and "half brass" sash bars, of nearly every form and size, are manufactured, as well as brass, copper, and zinc beads. Metal "stall board plates" hardly come within our province, except to notice them. With this subject is connected the varieties of *revolving shutters* in iron, wood, or steel, and with or without machinery; and made to lift up, or down, or to move sideways. A revolving safety shutter in one sheet of steel, is probably the last invention; it requires no machinery. Where the old method of putting up shutters exists, Jennings's *shop-shutter shoes* secure them as they are each put up, without the necessity of any shutter bar.

2255*g*. Wrought iron *wine bins*, and new registered iron bins adapted for small quantities of wine, placed in a closet in a sitting or other room, and with or without doors, will be found a useful addition in small houses.

2255*h*. The ornamental portion of SMITH's work has been largely introduced, of late years especially, in wrought iron shaped by hand into various devices and patterns, more especially according to the several periods of mediæval architecture. The taste is chiefly developed in gates, railings, altar and staircase standards, screens, grilles and gratings, tombs, hinge fronts, the band finishing either in a fleur de lys or trident, reaching to about three-fourths of the width of the door, and of ⅜ths iron; or in some scrollwork, which curls and scrolls over the entire face of the door; shutter hinges, common door hinges; gable crosses, terminals, vanes, and hipknobs; ridge crestings; drop handles with plates, closing rings and plates; lock plates and escutcheons, knockers, keys, latches and bolts, bell pulls, levers and plate pulls; umbrella stands; scrapers; fenders and fire-irons; dog grates; lecterns and book rests; candlesticks, gas, lamp, and candle pendants and brackets, desk lights, and standards; coronælucis, lanterns, and pillars. It is almost unnecessary to add that many of these articles are to be had in polished brass, and that many of them are imitated in cast iron. Wrought and cast iron, as in panelled work to gates, are sometimes employed together, the wrought parts enclosing the panels.

2255*i*. As iron has now neither the tenacity nor the ductility which it gained by the old process of being repeatedly forged, the modern smith can scarcely hope to emulate the fine works which were produced in mediæval times, unless the iron be made for the

purpose. It is not easy to repeat the mediæval operations of slotting a bar, so as to get the eyes at equal distances, without a machine; or of fastening hot (or, as in later times, cold) clips; or of cutting slits into a bar from the edge, and then curling the splintered parts; yet these were common work for the smith in the 12th century. It is equally difficult to produce the twisted work which was easy to the mediæval smith, whose chief care in the 13th and 14th centuries was bestowed in welding, stamping, and chiselling; the file was scarcely ever used. In welding he was careful to fire the two parts separately, getting the upper one to a white heat, the lower part to a red heat, and hammering the joint lightly at first, but harder as the iron grew colder. He disguised the uneven state of the upper part by punching on it separate dots, or else close ones, forming a sort of incised line.

2255j. In very large specimens of ancient work, some parts are additions entirely welded, others are additions confined at the ends by bands, which are welded across the groundwork. To imitate work of the 13th century, such as a grille, requires a drawing at full size, and a matrix for each leaf or bud, with an anvil cut to each section which a bar or a band is to assume; this last seems, with regard to the bar, to have been overlooked by M. Viollet le Duc. Then, when a bar has been rounded (if needful), and the end stamped, the curl is given and the smith has a stalk with a foot. Two of these must be applied to the drawing to have the point of junction marked, and the feet are to be welded together. If the sprigs then made are to be combined into branches, the larger stem is to be prepared; and, if moulded on the face, this was passed between the hammer and the cut anvil by a process equivalent to rolling the bar. After the sprigs are welded with the branch, the poverty of the joint is perhaps to be masked: usually the mask was a moulded band, to which an ornament, e.g. a cup of foliage, was sometimes added; but frequently the band was superseded by a stamped button. After the feet of the branches are welded to the trunk or main stem, bands are laid over the junction, are welded, and are finished with the chisel. The whole has to be riveted to the framework. The size and weight of the pieces at the last times of welding were difficulties that were partly obviated after 1250 by omitting the welded bands.

2255k. These operations were superseded by the introduction of sheet iron, in England before 1300, in Germany before 1400, and in France soon afterwards, which was cut and bossed to a remarkable extent, sometimes stamped, and frequently welded, but later was riveted. In work of the 15th century the bars are neither stamped nor chased, and the sheets are riveted instead of being welded; but later they are either planted or housed. Finally, the mediæval smith returned to the slots, mortises, and short bars of the earlier periods, and used clips which were closed cold with rivets of soft iron.

2255l. The FOUNDER, now more especially, is employed to supply ornamental fancy gates, sashes and frames, *rain water pipes* in 6 feet lengths, 2 to 8 in. in diameter, with their *cistern heads, offsets, elbows, branch pieces, shoes, union sockets,* and *ears* plain and ornamental. *Square rain water pipes,* 2½ in. square, 3 in. by 2½ in., 3 in. square; 3¼ in by 2 in.; 3½ in. by 2½ in., 3½ in. by 3¼ in.; 4 in. by 2½ in., 4 in. by 3 in., 4½ in. by 3 in., 4 in. square, and 5 in. by 3½ in. with branch pieces, shoes, ears, &c. *Rain water gutters* of all shapes and sizes, plain and moulded, *roof gutters* between slopes, square, angular, and square and angular. Pavement gutters, air or stench traps, scrapers, and coalplates, with many, if not all, of the articles required for "stable fittings" either plain, enamelled, or galvanized, as advertised by Varnel; Cottam and Hallen; the St. Pancras Iron Work Company; Musgrave, at Belfast; and others.

2256. The chief articles furnished by the IRONMONGER are for the joiner's use, and, except in particular cases, are kept in store by that tradesman for immediate supply as required.

2257. They consist in *screws* made in brass, copper and iron, whose common sizes are from three quarters of an inch up to 4 inches in length. They are sold by the dozen. *Self-boring wood screws,* the thread being made at a particular angle, are supplied in lengths of ½, ⅝, ¾, 1, 1¼, 1½, 1¾, 2, 2½, 3, 3½, and 4 inches. *Nails* are now both wrought, cut, and cast, and made of iron, copper, and zinc. They are called by a variety of names according to their special uses. See GLOSSARY, s. v. NAIL and ADHESION. The weight of *flooring brads* (wrought and cut) per 1000 (rarely exceeding 900 nails) is—

Wrought.		Patent Cut.		Thickness of floors.
Length.	Weight.	Length.	Weight.	
2 inch.	8 lb.	2 inch.	8 lb.	⅝ inch.
2¼ „	10 „	2¼ „	10 „	Inch.
2½ „	12 „	2½ „	12 „	Inch.
2¾ „	16 „	2¾ „	15 „	1¼ inch.
3 „	20 „	3 „	18 „	1½ „

Tacks are tinned over; and all nails can be galvanized to prevent their rusting. Nails for ornamental purposes, and likewise screws, are made with *brass heads*, and the latter also with *gilt heads*.

2258. *Butt hinges*, whose name is probably derived from butting close surface to surface when closed, are used for hanging doors and shutters, and made of wrought and cast iron and brass, the former varying in size from 1¼ to 4 inches in length; the latter from 1 inch to 4 inches. These, as well as all other hinges, are in size necessarily proportioned to the magnitude and consequent weight of the shutters or doors they are to carry; and it is to be observed, that for the well-hanging of a door or shutter, the size of the hinge should be rather on the outside of enough than under the mark. There is a species of hinge used for doors called the *rising joint hinge*, a contrivance in which the pivot, having on it a short portion of a spiral thread, and the part to which the door is fixed having a correspondent mass, the door in opening rises, and clears the carpet or other impediment usually placed on the floor. The *projecting brass butt* is used when the shutter or door is required to clear some projection, and thus, when opened, to lie completely back in a plane parallel to its direction when shut. All hinges are sold by the pair, including the necessary screws.

2258*a*. Besides these hinges, there are *cross garnets*, whose form is like the letter ⊢ sidewise. These are only used on the commonest external doors, and are made from 10 to 12 inches, varying in their dimensions by differences of two inches. H *hinges* are of the shape of the letter H, showing their form as well as the origin of their name; and in their sizes range from 4 to 12 inches by differences of an inch. HL *hinges* (H and L conjoined), whose form is implied by their name, and whose sizes are from 4 to 14 inches, proceed by inches. *Parliament hinges* are to allow a shutter to open back upon a wall, and are made of cast and wrought iron, from 3½ to 5 inches, proceeding in size by half inches.

2258*b*. Redmund's patent hinges consist of, iron rising butts; or in brass with moulded burnished knuckles and concealed joints; iron and brass projecting butts with moulded burnished knuckles, flaps and concealed joints, in three sizes of proportional strength, from 1¼ to 4½ inches projection; *pew hinges*, in iron and brass, projecting 1, 1½, and 2 inches. Rising *spring hinges* in iron; and not rising spring hinges, in brass, iron, and patent malleable iron, and of single and double action; these are made flush, the knuckle being made to suit the bead of the architrave; rising swing hinges, which rise and act each way; gate hinges of many descriptions, &c.

2258*c*. Collinge's patent spherical hinges run from 2 to 6 inches, in plain brass, ornamental brass, and cast iron. The gate or strap hinge, from 1 foot 6 inches to 3 feet 6 inches, in steps of three inches. Improved gate springs with hardened joints. Spring hinges, and also to open both ways, are made light, strong, and extra strong, for 1½, 2, 2¼, and 2½ inch doors, in iron and brass.

2258*d*. Among other useful hinges are, swing centres, double action, to open both ways, known as Smith's patent, Redmund's, and Gerish's, chiefly for 2 and 2½ inch doors. Hart's iron rod door springs, from 15 to 42 inches, called No. 1, No. 2, No. 3, and No. 4 qualities, also brass mounted. Circular door springs. Rising and not rising door back springs; spiral door springs; and patent climax door springs for single and double action doors, must also be noted for closing doors.

2259. *Rough rod bolts* are those in which there is no continued barrel for the bolt, and are for the most common service. Their sizes begin with a length of 3 inches, and proceed by inches up to a length of 10 inches; such, at least, are their common sizes. *Bright rod bolts* run of the same sizes as the last; and, as the name indicates, the bolt is polished and finished, so as to make them a better fastening, as far as appearance is concerned. The *spring plate bolt* is contrived with a spring to keep the bolt up to its work, but one which so soon gets out of order that we wonder it is now manufactured or used. It is made of lengths from 3 to 8 inches, by variations of an inch in size. *Barrelled bolts* are those in which the whole length of the bolt is enclosed in a continued cylindrical barrel, and are superior to all others in use, as well as the most finished in their appearance. Their common sizes are from 6 to 12 inches, varying by steps of an inch. All the bolts above mentioned are sold per piece by the ironmonger, as are those called *flush bolts*, a name given to such as are let into the surface to which they are applied, so as to stand flush with it. They are mostly made of brass, and are of two different thicknesses, viz. half and three quarter inch. Their lengths vary from 2½ to 12 inches, and occasionally, as circumstances may require, as in book-case doors and French sashes, to a greater length. But for French casements, what is called the *Espagnolette bolt*, a contrivance whose origin is French, though much improved in its manufacture here, is now more generally in use. Smith's *patent weather-tight casement fastenings for French windows*, consists of a plate formed in the edge of one door, which when shut is forced half its width into a groove in the other door. This acts in lieu of the Espagnolette bolt above mentioned. Smith's patent *water bar* for casements has been mentioned in pars. 2165*b*. and *d*, and 2255*b*. Jackson's patent *mortise bolt* appears to be a late improvement upon the round or the flush bolt.

2260. *Pullies*, for hanging sashes and shutters, are made of iron and of brass, and with

brass sheaves and brass axles. Their sizes are from one inch and a half to two inches and a half in diameter. M'Adam's pulleys for window sashes, of porcelain or vitreous material, are considered to be exempt from damp and rust through which cords may become rotten. He adds to them a method of hanging double sashes with a single weight on each side of the window. Austin's imperial patent sash and blind lines are made of flax, in four qualities. A common description is made from jute, but this sort has not the strength or durability of flax, and is not so good as the common cord lines. Newall's patent *copper wire cord* and *wire strand* are extensively used for window sash line, hothouses, lightning conductors, picture cord, clock cord, tent ropes, clothes lines, &c. The advantages, as reported, being that they are cheaper, much more durable, equally flexible, and one-sixth part the bulk. Newall's patent improved *iron wire rope*, we do not detail.

Table I. of Newall's Copper Cords.

Number	0	1	1½	1½	1¾	2	3	4	5	6	7	8	9	10
Diameter, inch	⅜					1/7	1/8	1/10						
	Lightning Conductor		For Window Sash Line, Hothouse, &c.							Picture Cord, &c.				
Breaking strain, lbs.	1260		960	690	480	300	180	125	45	90	120	128	130	300
Working load, in lbs.	336		224	168	112	75	45	31	11	22	30	32	50	80

Brass axle pulleys, and hothouse pulleys, are supplied to suit.

Table II. of Iron Cords—Galvanized and Plain.

Number	1	1¼	1½	1¾	2	3	4
Breaking strain, in pounds	2520	1920	1380	960	600	360	250
Working load, in pounds	672	448	326	224	150	90	60

Wire strand, 4 and 6 wire, of No. 3, 4, 5, 6, and 7 qualities; galvanized and ungalvanized.

2261. The varieties of locks, their contrivances for security, and their construction, are so many, that to describe them minutely would require almost a work of itself. All that the architect has to deal with, for common purposes in building, we shall mention. For fastening places where particular security is requisite, as strong closets for plate or cash, some of the patented locks should be used, and we must leave this matter for inquiry in the hands of the architect. Every patentee says his invention is the best. We nevertheless believe, notwithstanding the boasts of all the inventors, that no lock has appeared which an expert locksmith acquainted with its construction will not be able to pick. The locks in common use are *stock locks*, whose box is usually of wood, and whose sizes vary from 7 to 10 inches. *Dead locks*, whose sizes are from 4 to 7 inches, and so called from the key shooting the bolt home *dead*, without a spring. *Cupboard locks* of 3, 3½, and 4 inches in size. *Iron rim locks*, whose box or case is made of iron, and which are fitted on to one of the sides of a door, and whose sizes are from 6 to 8 inches. Of those made of the last-named size, there are some, as also of 9 inches, which are used for external doors, called *iron rim drawback locks*. For the doors of all well-finished apartments, *mortise locks* are used. These take their name from being mortised into the thickness of the door, and being thus hidden. Gerish's patent cylindrical mortise lock, Barron's patent locks, Bramah's patent locks, Chubb's patent locks, Hobbs' patent locks "are made for all purposes, from the smallest cabinet to the largest fortress gate." To these either plain or fancy *furniture*, that is, *knobs* and *escutcheons*, are affixed. Pitt's patent *self-adjusting spindle*, with his new patent *mount and spindle*, and Ager's patent *adjusting spindle*, all command a large sale. They are all fitted with knobs and plates, from china, plain white and buff, to gold lines, gold bands, flowers, &c., and in hard woods, as ebony, maple, satin, rose, mahogany, wainscot, and walnut; the knobs in many shapes: also with plain and fancy brass, brass and china combined, and buffalo horn furniture. Also with glass furniture, crystal and amber, of varying shapes and cutting, with green, black, and opal cut octagons. Above and below them *finger plates* are generally directed to be fixed, to prevent the door being soiled in the places where it is mostly caught.

2262. The different sorts of latches in use are the *thumb latch*, which receives its name from the thumb being placed on the lever to raise its latch; the *Norfolk-latch*, which is sunk, and requires a pressure on the lever to raise the latch; the *Suffolk-latch*; the four-inch *bow latch* with brass nobs; the brass *pulpit latch*; the *mortise latch*; and Gothic latches.

2262*a*. Adams and Son's *electric bells* for domestic use, has M. Breguet's (of Paris) patent indicator system, with a dial which shows when the bell is ringing. In Thomson and Co's patent *electric bells, electric fire alarms*, and *alarms for windows and doors*, the battery is con-

tinuous, requiring to be replenished but once (and at only a small cost) in twelve months. The wires can be covered with silk or cotton of the same colour as the decorations, to be practically invisible. Moseley's patent electric bells are fixed on the system of the battery not being in use when the bell is not ringing, therefore the wires cease to be, as in the French system, charged with electricity. The price appears to be, for a number of bells, from 25*s.* and upwards per pull. The ordinary crank system is noticed in SPECIFICATIONS, par. 2292. Wishaw's registered improved *telekouphonon* for speaking pipes, consists of a whistle mouthpiece of ivory, wood, or metal, with an indicator attached to point out from which one of two or more tubes the whistle proceeds.

2263. Besides the articles already mentioned, *spikes* of 5, 6, and 7 inch lengths, *holdfasts, wall hooks, door springs* of various sorts, *door chains* and *barrels, thumb screws* and other shutter and sash fastenings and shutter bars, *brass turn buckles, closet knobs, brass flush rings, brass rollers, bars with latchets, shelf brackets, drawer handles, sash weights,* besides many other articles, are furnished by the ironmonger.

2263*a*. In treating on SPECIFICATIONS, in a subsequent section, it will be seen how the several articles of smithery and ironmongery are applied.

2264. Bolts, straps, and other exposed iron work are preserved from the action of moisture on them by the following mixture :—To two quarts of boiling oil add half a pound of litharge, putting in small quantities at a time, and cautiously. Let it simmer over the fire two or three hours ; then strain it, and add a quarter of a pound of finely-pounded resin and a pound of white lead, keeping it at a gentle heat till the whole is well incorporated. It is to be used hot. A composition of oil and resin and finely levigated brickdust is found useful in preserving iron from rust. It is to be mixed, and used as a paint of the usual consistence (see par. 1780, *et seq.*). Wrought iron ornamental work exposed to the weather, has been cased with copper and gilt, as much for decoration as for preservation.

GAS FITTER.

2264*a*. The works of this artizan may be placed under the head of this section, although his trade is now kept distinct. The main distribution of gas is effected through cast iron pipes with sockets and spigot ends, whenever the diameter exceeds 2 inches. The various formulæ for calculating the velocity and the pressure of the effluent gas are to be found in CLEGG, *Treatise on Gas Lighting.* The most economical working pressure is equivalent to the weight of a column of water on the outlet, of about 1 inch. The formula for calculating the quantity discharged is $q = 1350 d^2 \sqrt{\frac{h\,d}{s\,l}}$; in which q = the quantity sought in cubic feet per hour ; d, the diameter of the pipe ; h, the working pressure in inches ; l, the length of the pipe in yards ; and s, the specific gravity of the gas compared with atmospheric air as unity.

TABLE OF THE DELIVERY PER HOUR THROUGH PIPES OF THE DIAMETERS NAMED.

Size. diameter.	Thickness.	Length.	Weight.	Delivery.	Cost of Laying.

2264*b*. In the details of house fittings, wrought iron pipes are used when the diameter is, and exceeds, half an inch ; ¾ in. is the least size recommended to be used, even for supplying upper rooms. For pipes of smaller diameters, and where abrupt bends have to be made, tin or composition pipes are fixed. For occasional use, flexible pipes are employed, such as those made of gutta percha, caoutchouc, with or without a wire coil inside,

and caoutchouc coated with varnish. This last is the safest of the flexible pipes; the other, though safer when used with a wire core, is not impermeable to gas, though a coat of linseed oil may render it so. The first-named is not only permeable, but causes an unpleasant smell, and is liable to contraction at any junctions with metal work, allowing of the escape of gas. Under no circumstances whatever should either iron or composition pipes be let into the plastering, as is too constantly done, or into solid brick or stone work; for the salts in the latter are liable to affect the pipes in a serious manner, and the contraction and expansion of their materials may injure the joints; whilst it must always be difficult to trace a leakage. When placed in a partition, the gas escaping fills all the spaces between the studs, and between the joists of the floors, so that when it comes in contact with a light the whole ignites, and the force of the explosion may cause the entire destruction of the house. The police regulations of Paris require that gas-pipes in houses should be visible throughout their length, excepting when they traverse floors, partitions, &c., when the pipe conveying the gas is required to be enclosed in a larger one, projecting beyond the floor or partition, so as to ensure ventilation round it. Copper pipes should never be used, on account of the action of the gas on the metal.

2264*c*. The form of *burner* which yields the best economical results is the argand; the bat's wing is the next best; and the fish-tail the worst. A number of small burners dispersed will give a better light than collections of them. For lighting large rooms, where it is not necessary to throw the light upon any particular space, the solar or sun-light arrangement is agreeable, and it is now fitted so as to promote the ventilation of the room. It is very costly, not only in its first establishment, partly from the necessity of securing the burners and pipes from setting fire to the surrounding timbers, but also in the subsequent consumption of gas. In rooms of moderate height, the heat to the occupants is objectionable. The argand burner, with 15 holes, will burn about 5½ to 8 feet per hour, according to the pressure; ordinary street lamps, having the bat's wing, burn 3 to 8 feet per hour, and are usually contracted for at the rate of 5½ feet. Bronner's burners afford a steady light, and are made to consume as many feet per hour as may be required.

2264*d*. As illustrations of the mode of *lighting* public buildings may be cited: I. The concert room at Liverpool, designed and executed by Mr. A. King; it is effected principally by carrying a pipe in the cove of the ceiling, which pipe is pierced with numerous holes for fish-tail burners. II. St. James's Hall, London, and the great hall of the Reform Club, which are admirable illustrations of the use of the stellar and of the solar lights. III. The new theatre du Chatelet, at Paris, where the lighting is effected by 1,300 burners placed above a vault of ground glass, and under a large enamelled reflector; the glass vault forms, in fact, the ceiling of the body of the house, so that the burners themselves are entirely hid. This arrangement was also employed for a few years at the picture gallery in Suffolk Street, London. And IV. The various passages and rooms of the Houses of Parliament, which are lighted and ventilated under Faraday's principle.

2264*e*. A notice was issued in January 1862, from the London Fire Engine Establishment, stating that, "It appears absolutely necessary that some steps should be taken to caution owners of property, particularly in large wharves and warehouses, as to the position and protection of the dangerous gas lights. These remarks may not be considered unnecessary when it is remembered that in many of the most valuable buildings in the metropolis moveable gas brackets are placed within 20 inches of the ceiling without the slightest protection whatever. It may be laid down as a rule that the jet on the outer arm of the bracket should never be less than 36 inches from the ceiling over it, and that it should be protected on the top by a hanging shade, and on the sides by stops on the swivel joints, which should prevent the brackets moving beyond a safe distance. Attention might, perhaps, also be called to the very common and dangerous practice of nailing tin or iron on the adjoining timbers. This has long proved to be no protection, and it has the disadvantage of allowing the timber to be charred completely through before it is known." In some places gas lights are used within 15 inches of the ceiling, and when the glass shade has been broken and not replaced, the heat has been known to ignite the floor timbers over the plastering.

2264*f*. It will not be necessary here to do more than mention the use of gas in the kitchen for boiling water, or for baking and roasting; the baths heated by gas, so readily adaptable in places where a coal stove cannot be used; or the several gas stoves for warming buildings and rooms.

2264*g*. The urgency of efficient *ventilation* when gas is burnt in a room habitually, is a subject of immediate importance. It is principally to the neglect of this precaution that the bulk of the injurious effects said to attend the use of gas may indeed be attributed. In the case of libraries, the destruction of book bindings may be assigned more justly to the heat than to the chemical action of the products of combustion. No doubt the bisulphide of carbon, which is present in even the most carefully purified gases, must give rise to the formation of minute quantities of sulphurous acid: and this, in its turn, must be destructive to some descriptions of leather—especially Russian (as noticed in the

Builder, vi. 89) · but a rapid removal of the products of combustion would almost entirely obviate this effect. It seems, however, that the excessive dryness and the heat of the air in the upper part of rooms where gas is burnt, may occasion the injury quite as much as the chemical reactions supposed to take place; the books which suffer most being always those placed above the level of the lamps. Under any circumstances, ventilation should take place close to the plane of the ceilings. Even when provision is made for ventilation over gas burners, a stratum of heated air is often allowed to stagnate over the openings, close under the line of the ceiling; and the area of the openings is rarely sufficient to allow the escape of the decomposed gases. Again, if any sulphurous acid should be produced, it will be found also to tarnish the colours of tapestry and hangings, and to turn imitation gold; hence none but the best leaf-gold should be employed in rooms where gas is burnt. The injury caused by the use of such gas as is supplied in London, Paris, Bruxelles, &c., is very small compared with the brilliance of the light; and the gas of Liverpool, Edinburgh, Manchester, and some other places having, bulk for bulk, a higher illuminating power than that of London, is even less injurious. Mr. Spencer has reported that the quantity of gas leaking from London gas pipes is not less than 9 per cent., or between six and seven million cubic feet per annum, which causes the stinking black earth of the London street subsoil: no such leakage occurs at Liverpool or Manchester, where the joints of the pipes are bored, turned, and fitted to each other, like ground stoppers in glass bottles; whereas in London the pipes are jointed with tow and lead, so that after expansion and contraction in summer and winter the perfection of the joints is destroyed. The gas then acting upon the subsoil forms sulphuretted carbon, which corrodes not only the gas pipes, but the water mains also, and converts them in ten years almost entirely into a sort of plumbago, although in pure London subsoil they last a century.

2264*k*. Wrought iron welded tubing for gas is made from 2 in. diameter, 1½ in., and then down by each ¼ in. to ½ in., then ⅜, ¼, and ⅛ in. diameter, in lengths of from 4 to 12 feet, from 2 to 4 feet, and shorter pieces under 2 feet; together with all their connecting pieces, cocks, taps, screws, &c. We have availed ourselves of G. R. Burnell's contribution to the *Dictionary of Architecture* for much of the information upon this subject here laid before the reader.

SECT. XI.

FOUNDERY.

2265. The very general use of cast iron by the architect induces us to give a succinct account of the common operations of foundery, or the art of casting metal into different forms. To gain a proper knowledge of the operations, the student should attend a few castings at the foundery itself, which will be more useful to him than all the description we could detail of it; however, we give a few particulars not noticed in the previous section on IRON. Some of the articles cast are noticed in par. 2255*k*.

2265*a*. Those manufacturers who will attend to the good quality of the irons they sell, can generally command their own price. Thus, the Low Moor and the Bowling bar irons continue in possession of the market at nominally high prices, whilst the ordinary irons are hardly saleable at remunerative ones. The Welsh iron, known as the SC brands, or the Staffordshire mitre iron, are of at least equal quality to the above, and there are others as good. The average price of Welsh bars is usually 1*l*. per ton below that of the Staffordshire bars, and the latter are sold at about 10*s*. per ton below the price of the Yorkshire bars, a tolerably fair indication of their respective values. Another test is the mean average prices of pig iron at the furnaces throughout the kingdom, which for the year 1858, were about 3*l*. 2*s*. per ton. Locally, the prices at the furnaces varied as follows:—

	£	*s.*	*d.*		£	*s.*	*d.*
Scotch pig, mixed numbers -	2	17	3	Yorkshire, mixed numbers -	3	5	0
Durham „ - -	3	3	0	Staffordshire „ - -	2	17	0
Cleveland „ - -	2	14	6	Welsh „ - -	3	15	0

2265*b*. Staffordshire, Shropshire, and Derbyshire, afford the best irons for castings. The Scotch iron is much esteemed for hollow wares, and has a beautifully smooth surface, which may be noticed in the stoves and other articles cast by the Carron Company. The Welsh pig iron is principally used for conversion into bar iron. Almost all irons are improved by admixture with others, and therefore, where superior castings are required, they should not be run direct from the smelting furnace; but the metal should be remelted in a cupola furnace, which gives the opportunity of suiting the quality of the iron to its intended use. Thus, for delicate ornamental work, a soft and very fluid iron will be required, whilst for girders and castings exposed to cross strain, the metal will require to be harder and more tenacious. For bed plates and castings, which have merely to sustain a compressing

force, the chief point to be attended to is the hardness of the metal. Various mixtures of different qualities of iron have been recommended as materials for large castings (see Fairbairn's *Application of Iron, &c.* 65.). Most engineers are agreed in considering that the best course for an engineer to take, in order to obtain iron of a certain strength for a proposed structure, is, not to specify to the founder any particular mixture, but to specify a certain minimum strength which the iron should exert when tested by experiment.

2265*c*. As noticed in a previous chapter, the ores are smelted by cold and hot air blasts. The latter iron makes very fine castings, but is deficient in tenacity, and requires great care in its application to the purposes of machinery, and for girder castings, by employing it as second runnings from the cupola, and mixing third-class pig iron with the first. On account of some defects in it, hot blast iron should be excluded from all such works as girder bridges, machinery castings, &c., and from the preparation of bar iron where great strength in the metal is required. It appears that there are no means of detecting hot or cold blast irons in pig castings. Whenever great strength is required, air furnaces instead of cupolas should be used, and where it is not connected with too great an expense, loam instead of green sand should be used for moulding.

2265*d*. Table of the Weight of Cast Iron per Foot Superficial. (Hurst.)
The weight of a cubic foot is put at 456 lbs. and 460 lbs.

Thickness in inches -	$\frac{1}{16}$	$\frac{1}{8}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$	$\frac{3}{8}$	$\frac{7}{16}$	$\frac{1}{2}$
Weight in pounds -	2·34	4·68	7·03	9·37	11·72	14·06	16·40	18·75
Thickness in inches -	$\frac{9}{16}$	$\frac{5}{8}$	$\frac{11}{16}$	$\frac{3}{4}$	$\frac{13}{16}$	$\frac{7}{8}$	$\frac{15}{16}$	1
Weight in pounds -	21·09	23·44	25·78	28·12	30·47	32·81	35·16	37·50

2265*e*. Collinson's Mansfield moulding sand has a wide reputation among the modellers of the finest brass and iron castings, arising, no doubt, partly from its exquisite fineness of grain, but more particularly from its clay-like adhesiveness and plaster quality, combined with a total freedom from any coarse or gritty particles. It is found under a deep deposit of coarse sand, ordinarily known as building sand, and within a short distance of the well-known white and red Mansfield stone quarries, in Nottinghamshire. The Isle of Wight sands are also used for the purpose. The sand usually employed in casting is of a soft yellow and clammy nature, over which, in the mould, charcoal is strewed. Upon the sand properly prepared, the wood or metal models of what is intended to be cast are applied to the mould, and pressed so as to leave their impression upon the sand. Canals are provided for the metal, when melted, to run through. After the frame is finished, the patterns are taken out by loosening them all round, that the sand may not give way. The other half of the mould is then worked with the same patterns, in a similar frame, but having pins which, entering into holes that correspond to it in the other, cause the two cavities of the pattern exactly to fall on each other. The frame thus moulded comes now under the care of the melter, who prepares it for the reception of the metal.

2265*f*. In making patterns for cast iron, an allowance is always made of about one-eighth of an inch per foot for the contraction of the metal in cooling. And it may be also requisite that the patterns should be slightly bevelled, that they may be drawn out of the sand without injuring the impression; for this purpose, $\frac{1}{16}$ of an inch in 6 inches is sufficient.

2265*g*. All castings should be kept as nearly as possible of the same bulk, in order that the cooling may take place equably. It is of importance to prevent air-bubbles in castings, and the more time there is allowed for cooling the better, because, when rapidly cooled, the iron does not become so tough as when gradually cooled. It is important in any casting to have the metal as uniform as possible, and not of different sorts, for different sorts will shrink differently, and thus will be caused an unequal tension among the parts of the metal, which will impair its strength; and, beyond this, an unevenness is produced by such mixture on the surface of the casting, for different sorts can never be perfectly blended together.

2265*h*. Castings should show on the outer surface, a smooth, clear, and continuous skin, with regular faces and sharp angles. When broken, the surface of fracture should be of a light bluish grey colour, and close-grained texture, with considerable metallic lustre; both colour and texture should be uniform, except that near the skin the colour may be somewhat lighter and the grain closer; if the fractured surface is mottled, either with patches of darker or lighter iron, or with crystalline patches, the casting will be unsafe; and it will be still more unsafe if it contains air-bubbles. The iron should be soft enough to be slightly indented by a blow of a hammer on an edge of a casting. Castings are tested for

air-bubbles by ringing them with a hammer all over the surface. Iron becomes more compact and sound by being cast under pressure; and hence cannon, pipes, columns, &c., are stronger when cast in a vertical than in a horizontal position, and stronger still when provided with a *head* or additional length, whose weight serves to compress the mass of iron in the mould below it. The air-bubbles ascend and collect in the head, which is broken off when the casting is cool Care should be taken not to cut or remove the skin of a piece of cast iron at those points where the stress is intense.

2265*i*. *Malleable cast iron* is made by embedding the castings to be made malleable in the powder of red hæmatite. They are then raised to a bright red heat, which occupies about twenty-four hours, maintained at that heat for a period varying from three to five days, according to the size of the casting, and allowed to cool, which occupies about twenty-four hours more. The oxygen of the hæmatite extracts part of the carbon from the cast iron, which is thus converted into a sort of soft steel; and its tenacity, according to experiments by Messrs. A. More and Son, becomes more than 48,000 lbs. per square inch. (Rankine.)

2266. The foundery of statues, which is among the most difficult of its branches, belongs exclusively to the sculptor, and is usually carried on in bronze. The execution of the bronze castings, made by the firm of Barbedienne of Paris, is attributed mainly, after the skill of the modeller, to the fineness of the sand, which can only be obtained at Fontenay-aux-Roses, in France. When new it is yellow in colour, but on account of its cost it is mixed in well-ascertained proportions with the old sand, which has become black, the mixture forming a good combination for the mould; other sands are considered to have too much silex in them, whereas the Fontenay sand has exactly the proportion necessary for the fineness of the work.

SECT. XII.

PAINTING, GILDING, PAPER-HANGING, ETC.

2267. Painting is the art of covering the surfaces of wood, iron, and other materials with a mucilaginous substance, which acquiring hardness by exposure to the air, protects the material to which it is applied from the effects of the weather. The processes employed in house painting were described by the editor at the Institute of British Architects, *Transactions*, Nov. 1857.

2268. The requisite tools of the painter are—*brushes of hog's bristles*, of various sizes suitable to the work; a *scraping or pallet knife*; *earthen pots* to hold the colours; a *tin can* for turpentine; a *grinding stone and muller*, &c. The stone should be hard and close-grained, about 18 inches in diameter, and of sufficient weight to keep it steady. The knots, especially of fir, in painting new work, will destroy its good effect if they be not first properly *killed*, as the painters term it. The best way of effecting this is by laying upon those knots which retain any turpentine a considerable substance of lime immediately after it is slaked. This is done with a stopping knife, and the process dries and burns out the turpentine which the knots contain. When the lime has remained on about four and twenty hours, it is to be scraped off, and the knots must be painted over with what is called *size knotting*, a composition of red and white lead ground very fine with water on a stone, and mixed with strong double glue size, and used warm. If doubts exist of their still remaining unkilled, they may be then painted over with red and white lead ground very fine in linseed oil, and mixed with a portion of that oil, taking care to rub them down with sand paper each time after covering them when dry; so that they may not appear more raised than the other parts. When the knotting is completed, the *priming colour* is laid on. The priming colour is composed of white and a little red lead mixed thin with linseed oil. One pound of it will cover from 18 to 20 yards. When the primer is quite dry, if the work is intended to be finished white, mix white lead and a very small portion of red with linseed oil, adding a little quantity of spirits of turpentine for second colouring the work. Of this second primer, one pound will cover about 10 to 12 square yards. The work should now remain for some days to harden; and before laying on the third coat, it should be rubbed down with fine sand paper, and stopped with oil putty wherever it may be necessary. If the knots still show through, they should be covered with silver leaf, laid on with japanned gold size. The third coat is white lead mixed with linseed oil and turpentine in equal portions, and a pound will cover about 8 square yards. If the work is not to be finished white, the other requisite colour will of course be mixed with the white lead, as in the case of four coats being used. When the work is to be finished with four coats, the finishing coat should be of good old white lead as the basis, thinned with bleached linseed oil and spirits of turpentine; one of oil to two of turpentine. If the work is to be finished *dead white*, the very best old lead must be used, and thinned entirely with spirits of turpentine.

2269. When stucco is to be painted, it will require one more coat than wood-work; the

last coat being mixed, if the work is as usually executed, with half spirits of turpentine and half oil, for the reception of the finishing coat of all turpentine or *flatting*. If the work be not flatted, the finishing coat should be with one part oil and two of turpentine. It would be impossible to enter into the details which are to be observed in painting walls of fancy colours; all that can be said on this point in instruction to the architect is, that when fancy colours, as they are called, which in these days a painter construes as anything but white and a tinge of ochre or umber, each coat must incline, as it is laid on, more and more to the colour which the work is intended to bear when finished.

2270. In repainting old work, it should be well rubbed down with dry pumice stone, and then carefully dusted off, and when requisite, the cracks and openings must be well stopped with oil putty. After this, a mixture of white, with a very small portion of red lead, with equal parts of oil and turpentine, is used to paint the work, which the painters technically call second colouring old work. After this, the work being dry, a mixture of old white lead, adding a small portion of blue black in a medium of half bleached oil and half turpentine, is used for finishing, or, if flatting be intended, the former preparation will be suitable for receiving dead white or any fancy colour. The same process will serve for stuccoed walls, observing that, if more coats be required, the mixture of half oil and half turpentine is proper.

2271. In respect to outside work, the use of turpentine is to be avoided, for turpentine is more susceptible of water than oil, and thence not so well calculated to preserve work exposed to the weather. Oil, however, having from its nature a natural tendency to discolour white, that is necessarily finished with a portion of half oil and half turpentine; but in dark colours this is not necessary, and in such cases, boiled oil, with a little turpentine, is the best, or indeed boiled oil only.

2271*a*. When linseed oil is clarified and cleansed by means of sulphuric acid, much of the cohesion in the vegetable property of the oil is destroyed, preventing its forming that perfect pellicle which it invariably does upon exposure to the atmosphere during drying. White lead should be ground with linseed oil in its pure state; this oil is now largely adulterated with oils of resin and pine, as those oils are very much cheaper. Oils are thus clarified that the lead, when ground, may appear at once as white as possible; whereas, if ground in pure linseed oil which has had the refuse cast down by means of ivory black or powdered litharge, it will at first have a yellow tinge, which is only to be got rid of by time; and hence arises the value of old ground white lead. (*Builder*, xiv).

2271*b*. The blackness which in the winter frequently shows itself upon exterior painted work probably arises from the outer skin of the oil having been rendered porous by the sulphuric acid, and the foul, or hydrogen gas, readily fastens itself to the unprotected lead, for which it has an affinity, and hence results the mottled appearance of such work.

2271*c*. The best linseed oil is obtained from good Baltic and Bombay linseed, crushed. Mineral turpentine is sometimes used as an adulteration of that article; the paint made with it dries, and then softens, becoming sticky even under a coat of sugar of lead and varnish. Woodwork prepared with bad linseed oil for being stained, prevents the varnish from drying: good size is all that is required. To distinguish the good and bad qualities, states a writer in the *Builder*, xxi. p. 919, pure vegetable turpentine, upon exposure to the air, always loses in bulk by evaporation, but gains in weight by absorption of oxygen, which makes it more binding in its properties. This peculiarity none of the mineral substitutes possess; on the contrary, the mineral is so extremely volatile that, upon exposure, the spirit all flies off, leaving the oil without anything to assist it to harden, and of course increases the evil of the bad oil, instead of counteracting it. The use of varnish in white lead work cannot be sufficiently reprehended, on account of the ultimate defect of the work.

2271*d*. Nut oil has been stated to be more durable, and to stand the weather much longer than any other oil in paint.

2272. White lead, which is the principal basis of all stone colours, is carbonate of lead, generally containing hydrated oxide of lead, which is sometimes combined in the proportion of one atom of hydrated oxide to two of carbonate of lead. It is usually made either by precipitation, as when carbonic acid or a carbonate is used to decompose a soluble salt, or a subsalt of lead: or by exposing plates of cast lead to the joint action of the vapour of acetic acid air and carbonic acid. It is by the latter process only that the resulting carbonate of lead is obtained of that degree of density, opacity, and perfect freedom from crystalline texture, which fits it for paint. The last, called the Dutch process, was introduced into England about 1780. White lead is often largely adulterated with sulphate of baryta, which may be detected by insolubility in dilute nitric acid, whereas pure white lead is entirely dissolved by it. Fine lead is now made from *slag lead*, which is treated with nitrate of soda, thus oxidising all impurities except copper. The same effect is accomplished by calcining the lead in an improving furnace, especially when the lead contains much antimony. The copper is next removed by a process not yet published, and finally the lead is crystallised by Pattinson's process. The resulting metal is remarkable for its fine crystalline surface and bold columnar fracture. Lead containing even only 2¼ ounces

of copper per ton communicates a pink tint to the corrosions of white lead, which it is important to remove.

2272*a*. The ill effects on the constitution of persons engaged both in the manufacture and use of the article, have recently (since the publication of the first edition of this work) induced the French chemists to find some less deleterious substitute for it, and M. de Ruolz has discovered two substances which fulfil the required conditions—viz., combination with oil, good colour, property of concealing, &c. The first is an arsenical compound (product) hitherto little known, which M. de Ruolz does not describe, because, although inoffensive, it may be made by very simple chemical reaction, to retake its poisonous qualities, and be employed criminally. The second, which he considers well adapted for use, is the oxide of antimony, and possesses the following properties: its colour is a very pure white, rivalling the finest silver white, it is very easily ground, and forms with oil an unctuous and cohesive mixture; comparatively with the white lead of Holland as 46 to 22, mixed with other paints it gives much clearer and softer tones than white lead. It may be obtained directly from the natural sulphuret of antimony, and at one-third of the cost of ordinary white paint. (See *Literary Gazette*, Nov. 25, 1843.) If the finishing colour is white, nothing but white lead should be employed.

2272*b*. The other metallic white paint used is Hubbuck's patent *zinc white*, known for its intense whiteness, its resistance to sulphurous and other deteriorating causes, and its harmless qualities to the painter and the inmates of the house under decoration. It is requisite that the oil used should be as white as possible, that the brushes and pots should not have been used for white lead, or else have been cleaned with spirits; and that driers and colours with a lead basis should not be mixed with it. *Zinc white* possesses less body than white lead, and great care is requisite that the colour when ground in oil is of sufficient consistence to be laid on a flat surface without showing through; for in that state any oil in excess will form a slight glutinous coating on the surface, retaining every particle of dust brought in contact with it, until it has evaporated. Proper drying oils will cause zinc white to dry as quickly as the other colour. With these precautions, a few trials will enable any painter who is willing to work zinc white to overcome the difficulties which appear at first to condemn the invention. It is asserted that in consequence of the great durability of the colour of this material, a house painted with it may be washed for a succession of three, four, or even five years; and that after each successive washing, the surface will be found as clear and bright as when fresh painted. The effect, in appearance, of this paint is perhaps better when it is applied as a finish to a coat of pure white lead; generally it looks better on new work than on old, as some specimens prove that it was then apt to turn black. An American discovery consists in subjecting the oxide of zinc, in its dry state, to the combined action of friction and pressure, by which means its bulk is greatly reduced, and it is enabled to be ground with a reduced quantity of oil, while a greater body is given to the paint. Hubbuck states that 2 cwt. of his paint, with 6 gallons of oil, covers as much surface as 3 cwt. of white lead and 12 gallons of oil; and that it is cheaper also than white lead.

2272*c*. Lead colours are formed by a mixture of white lead with lamp black; all colours, however, that are called *fancy colours*, have white lead for their basis, chocolates, black, brown, and wainscot only excepted. The *fancy colours* are drabs, French greys, peach blossom, lilac, light greens, patent greens, blues, vermilion, lake, &c.

2273. There is a process used by painters termed *clear-coleing*, which is executed with white lead ground in water, and mixed with size. This is used instead of a coat of paint; but it has not sufficient body usefully to answer the end for which it is usually employed. It prevents the oil paint sinking into the wood; it scales off, and in damp situations its colour almost immediately changes. The only occasions wherein it is useful, are where the work is greasy and smoky, in which the use of it prepares better for the reception of paint. It should, however, never be employed upon joiner's work or cornices to ceilings, where much enrichment is found; for, of all things, it destroys the sharpness and beauty of the ornaments. Painters are very fond of using it; but their endeavours to persuade the architect should always be resisted, except in cases of absolute necessity, namely, that in which a fair appearance cannot otherwise be given to the work. The old work should be well cleaned and dried, and then the mixture above stated applied. For finishing, the white lead is mixed in half linseed oil and half turpentine, and used as stiff as possible; blue black, or some colour, and a little drier, are requisite.

2273*a*. Various prepared paints are employed. One of the oldest is Carson's *Anticorrosion paint*, used for out-door work only, such as farm buildings, implements, fencing, &c., all kinds of iron work, brick, stone, compo, &c. It is stated to be lower in price and as lasting twice as long as the best white lead. The powder, in which state it is supplied, is composed of ground glass bottles, scoriæ from lead works, burnt oyster shells, and the required matter for the colour that may be chosen. 112 lbs. of this paint requires 7 gallons of raw linseed oil and 1 gallon of turpentine; to be mixed over-night; 2 coats are required on paint 3 on new work; 3 or 4 on brick, compo, &c.; everything to be well scraped first,

and the paint rubbed in well. It is thus more laborious to put on than common paint; it wears out the brushes in a very short time, and as it lasts so long, painters will seldom use it. The appearance of a surface painted with it is rough, resembling that of unrubbed cast iron or freestone. It will blunt the edges of carpenters' tools when being sawn or cut through.

2273*b*. *Oxide of iron paint*, of various colours, is a ferruginous paint, for iron and wood, made at Matlock. Messrs. Peacock and Buchan have successfully applied their *improved coating composition* to many iron vessels and life boats, for many years, and it is found to preserve the plates, keep the iron cleaner, and to stand the sea air and salt water much better than most, if not all, other paints. The *Pure Carbon paint* protects iron from rust, and is valuable for all outside work. When *tar* is used as a paint, about a pint of spirits of turpentine is put to a gallon of tar as driers, or a larger quantity if it be required to dry quickly. The addition of yellow ochre will change the black to several shades of brown.

2273*c*. The *Bideford and mineral black paint* has been exclusively used in H. M. dockyards, &c., for the last forty years. "Its superiority is observable in the preservation of wood, iron, and canvas; it covers the work well, dries quick and hard, is more durable, and does not blister like other blacks, and has a body inferior only to white lead." The *Torbay iron paints*, made at Brixham, in Devonshire, have been much used in dockyards, &c, for coating materials under water, or in a position to be affected by damp. Their peculiar characteristics are, great covering properties, 62 lbs. effectually coating as large a surface as 112 lbs. of lead paint; economy, durability, protection of iron from corrosion, arresting oxidation at any stage, and resistance to sulphurous and other gases. (Hunt, *Handbook*, 1862. *Builder*, xx. 527.)

2273*d*. The *Iron minium paint*, by A. de Cartier, manufactured at Auderghem, near Bruxelles, is a pure oxide of iron mixed with about one-fourth its weight of siliceous clay, and not containing any acids. It is now extensively used in this and other countries for painting the ironwork of ships, gas-holders, &c., superseding red lead and other pigments for such purposes. It is said to be solid, durable, cheap, and, above all, to preserve iron from oxidation, and of hardening wood. It is a dark brown in colour, but mixes easily with other colours, such as black, yellow, green, &c. To test its purity, it is said to be sufficient to dilute it with a small quantity of water, spreading it on paper, when, if pure, the edges of the paper will preserve the special tint of the iron minium. If a change of tint is perceived, an adulteration has been effected.

2273*e*. Warner's *Silicate of iron paint* is sold prepared in genuine boiled linseed oil, of a great variety of colours, for painting iron work. It is said to stand extreme heat and damp, and not to be affected by the strongest acid, sea water, sulphuretted hydrogen, or ammonia; and to be equally well adapted for iron or wood. It adheres so tenaciously, that sheet iron may be bent until it breaks, without the paint coming off. The powder, when boiled up with tar, is a very cheap preservative for iron or wood.

2273*f*. When visiting Paris in 1860, the present editor was much struck with the appearance of the margins of the stairs at the hotel. On examination, they proved to be covered with a thickish coat of a hard compound, having rather a glossy surface, and somewhat of a light orange tinge. A water-closet which had been out of order on one morning was not only repaired, but the seat and riser, the floor, and the wall to a height of three feet, covered with this mixture, and ready for use by the next day. The tiled floor of the manuscript room at the library of St. Génévière, which had been covered with the same mixture, was then in various stages of obliteration according to the traffic. The attendant there spoke very highly in favour of its cleanliness. It is believed to be composed of 10 lbs. of purified yellow wax, 10 lbs. of linseed oil, 8 lbs. of spirits of turpentine, and 5 lbs of common resin. The wax is dissolved separately in the linseed oil, and the resin in the spirits of turpentine by heat, and are subsequently intimately mixed, when they form a pasty compound. In this condition it is used as priming, being nearly colourless after application. Pigments ground up in oil in the usual way are added in the proportion of one-third of the vehicle, and then spirits of turpentine added in quantity sufficient to produce the desired amount of liquidity. So soon as the turpentine has evaporated, the coat of paint will support rubbing, if not too hard, without damage, but it takes some time to become *completely* hard. It is put on in one coat, without apparently any of the smell or inconveniences attending the ordinary process of painting.

2273*g*. The use of *distemper* is older than that of oil and varnish. *Whitewashing* is a kind of distemper, especially when size is used with it. Common distemper colour for walls is Spanish white, or *whiting*, broken into water, to which is added strong size whilst warm, and then allowed to cool, when it should appear a thin jelly; two coats are generally necessary. The old work should be first washed by a brush with water. This process in old publications is called, "painting in water colours." It is much used for ceilings, and always requires two, and sometimes three, coats, to give it an uniform appearance. It is not generally known that walls which have been distempered cannot afterwards be *limewhited*, in consequence of the lime when laid on whiting turning yellow; oil colours, however, can be applied, and then white lead is used as the vehicle. Papered rooms

coloured in this manner, especially over flock papers, look well, as the raised pattern can be seen through the coats of colour. Rooms may be distempered and dry again in a day, with little dirt. When wood is covered with distemper, it is liable to swell with the damp. Rooms that are to be afterwards *varnished* are prepared in two ways: I. By applying the intended distemper colour, and then covering it with as many coats of varnish, coloured or uncoloured, as may be required; but if the wood be not dry, the colour becomes hardened and flakes off. II. The colour is ground and mixed up with varnish, which produces a better result. If the last coat of varnish be applied colourless, it then forms a glazing to the under tints, and its brilliancy will be greater. The use of size here, again, produces a considerable saving of varnish. For new plaster work a coating of size is desirable.

2273*h*. *Distemper*, and *fresco painting*, are subjects we do not think well to treat in this section, as they would come under "Decorative painting," a higher branch of artistic skill.

2274. Some colours dry badly, black especially, and in damp weather they require a *drier*, as it is called, which may be made from equal parts of copperas and litharge, ground very fine, and added according to circumstances. Drying oil is made as follows:—To 1 gallon of linseed oil, put 1 lb. of red lead, 1 lb. of umber, and 1 lb. of litharge, and boil them together for two or three hours. Great care must be taken that the oil does not boil over, on account of the danger to which the premises would be thereby exposed. Thus, in a pot capable of holding fifteen gallons, it would not be prudent to boil more than one-third of that quantity.

2275. Painters' putty is made of whiting and linseed oil, well beaten together.

2276. *Graining* (or *combing*, as it is termed, in some late specifications) and *marbling*, or the imitation of real woods and marbles, is done by the painter. *Mahogany grained* in 1798 is the earliest notice the writer on the subject in the Architectural Publication Society's *Dictionary*, had found; *grained wainscot* appeared in 1815. Imitation *wainscot* is obtained by giving the painted work a coat *in oil* of a brownish tone, the colour being thicker than usual; this is then scratched over by combs of bone, with blunt points, and of various degrees of coarseness, leaving the ground visible. The cross white veins or *champs* are next taken out with the corners of a piece of soft leather doubled up. The next process, which in cheap work is omitted or carelessly done, is *over-veining*; this is effected with a wide flat brush, the hairs of which are long and slender, dipped in transparent colour, when the hairs stick together in a sort of lock; the cross veins of the wood are dexterously imitated with this tool, and show the other veins below. Other expedients have been devised to imitate knots, veins, mottles, &c., of various woods. The little dark spots with a lighter shade round them in maple wood, are imitated by dexterous touches with the tips of the fingers on the wet pigment. Almost every other wood, as well as wainscot, is imitated in distemper, for which small beer and water, mixed with Vandyke brown and burnt sienna, according to the tint required, is found to be sufficiently glutinous without the aid of size, to prevent it smearing during the application of the coat of copal varnish which follows soon afterwards. Graining operations are always done after the wood has been painted; in best work, indeed, the coats are thicker than usual to afford a good ground for the combing. Taken with the subsequent varnishing, grained work is considered to be more lasting than painted work. Certain tools have been invented for performing this work; the grain has been imitated by machinery; and grained papers have been printed from the grain of the wood itself. To save the delay consequent on painting and all its annoyances, the editor of this edition explained, in 1857–8, his system of graining on the wood itself, whereby only a preparatory sizing is necessary; the result is that scarcely any smell of paint is perceived; a greater brilliancy in effect is attained; and the woodwork may be left to dry until the last moment.

2276*a*. *Marbling* is painting on a prepared painted surface, an imitation of the material as exact as the talent of the painter will admit, and requires no detailed explanation.

2276*b*. *Varnishing*, a subsequent operation to both of the above processes, requires much care and the use of good material, the best copal varnish, to bring out the colours of the work. Many qualities of varnish are manufactured, as;—finest copal for imitation woods, &c.; copal oak, for grained interior work; mahogany varnish, being darker in colour; fine hard-drying oak varnish, drying in about 8 hours, and used for seats in churches, &c.; dark hard-drying oak varnish, used after deal has been stained; paper varnish, for paper-hangings, &c. Where expense is not an object, two or three coats are applied, especially to marbling, each coat being well rubbed down to obtain an even surface and a high degree of polish. To restore the gloss of varnished graining, of marbling, or of varnished paper, the whole must be well cleaned, then sized afresh, and revarnished. But the original colour of the work can never be fully reproduced, as the varnish darkens by time. Brunswick black varnish, a quick drying jet black, is used for grates, iron work, &c. Copal cabinet varnish, and a white, and a brown, hard varnish, and French polish, are used for cabinet-makers' work. A water flatting varnish renders paperhangings washable without imparting a gloss. These varnishes are all as made by Mander, Brothers, Wolverhampton.

2276*c*. To clean varnished work, soap and water applied carefully with a sponge, and

the use of warm woollen cloths to dry the work, is very efficacious. The steps of wooden staircases, painted, grained, and varnished, last a very long time, and neither dust nor dirt adhere so easily to such work, as to paint. Real woods, especially wainscot, are prepared for receiving coats of varnish, by being first sized to prevent the rise of the grain which ensues when the slightest quantity of water touches it. When to be polished, they are well smudged over a short time previously, with Russian tallow. A preparation called *Lethicium* is said to remove paint from wood in twenty minutes, doing away with the necessity for burning it off. A *hypo-nitro kali* has been introduced for the same purpose.

2276*d*. *Sand paper, glass paper, emery paper*, and *emery cloth*, of various degrees of fineness are employed to rub down work to a surface. It is made by the pulverized material being placed in fine sieves, and by a gentle motion, distributing it by hand over the paper or cloth prepared for its reception.

2276*e*. *Stains*, as substitutes for paint, the tints resembling oak, mahogany, rosewood, walnut, and satinwood, cause the natural grain of the deal on which they are applied, to appear. The wood is then sized and varnished; their durability is stated to be at least three times that of paint in interior work, and only at half the cost. This is Stephen's preparation. Naylor's *stain* is said not to require sizing, and to stand exposure to the weather. Swinburn's *Transparent staining and anti-dry rot fluids* are chemically prepared, and show the natural grain and feathery appearance of the wood. When sized and the proper varnish used, they are said not to fade or blister by exposure to the weather.

2277. In the outside work and stairs, the process of *sanding* is frequently adopted. It is performed with fine sand thrown on the last coat of paint while wet. Cement work is generally *coloured* with its own cement mixed up with water. Roman cement or black cement, as it is sometimes called, must have a wash or two; and while Portland cement is declared not to require any colouring, certain it is, that in London, not many years pass over before its dirty look urges a colouring or painting process. The process of painting the artificial cements, such as Parian, &c., is noticed in par. 2251*f*.

2277*a*. *Gilding* is of two kinds, burnished, and mat or dead, gilding. The former is seldom used in architectural decoration. The latter is done in oil-size on woodwork; in water-size on plastering. The gold leaf of various thicknesses, but generally about $\frac{1}{23\frac{1}{200}}$ of an inch, is called "single," "double," and "thirds," and of tints, is furnished in books of 25 leaves, each leaf being $3\frac{1}{8}$ by 3 inches, or in the book 18 inches and $\frac{9}{8}$ of an inch superficial, covering about 1 foot of plain work. It should not be too thin nor have too much alloy. Gilding on metal is effected by first giving it a coat of paint or some other substance to prevent oxidation. Gold, absolutely pure and of extra thickness was applied to the iron-work of the great tower at Westminster; and double gold leaf, pure, was used in the reading room of the British Museum. It has been stated, that if just before commencing to gild, each leaf of the book be *slightly* rubbed over with wax, sufficient only to cause the adhesion of the gold, that gilding in the open air, even in windy weather, may be done without the loss of a leaf, as the stickiness of the gold-size will overcome that of the wax, and no part be blown away, as is generally the case.

2277*b*. A *gold paint*, patented by H. Bessemer, is now much used, which, by the highly improved manufacture of bronze powder, has greatly reduced its price in England, although very much is still purchased from the German dealers. As an impalpable metallic powder, its application to plaster, wood, &c., is effected by using a camels' hair brush, which is dipped into a little of the powder and rubbed up in a small portion of transparent gummy varnish, by which it adheres to the surface. For all outdoor works it requires to be varnished over for better preservation.

2278. With painting is often connected the practice of *paper-hanging* by the same artificer. The various sorts of paper used for lining walls it would be useless to describe. We have only to mention that papers are printed 12 yards in length, such a length being called a *piece*, and 1 foot 8 inches wide; hence, 1 yard in length contains 5 feet superficial; therefore, any number of superficial feet divided by 60 (the length 36 × 1 ft. 8 ins.) will give the number of pieces wanted for the work; 1 piece in 7 or 8 is allowed for cutting and waste to common papers, and any odd yards are allowed as a piece. French papers contain about $4\frac{1}{2}$ yards superficial per piece, being of various widths. In best papers this allowance for waste is not enough. Borders are 12 yards or 36 feet in each length, each being technically *a dozen*. A ream of printed paper of 20 quires of 24 sheets to the quire, is equal to 28 pieces of paper, or each piece contains 17 sheets. Arsenical green in printed papers is considered injurious to health, from its flaking off in light particles, and floating in the air, when it is taken into the lungs while breathing. This colour may be at once detected by placing a few drops of ammonia on it, whereby the green will be changed into a deep blue. The methods of manufacturing marble, granite, and wainscot wall papers, is well described in the *Builder* for 1865, page 912, and which need not be here entered upon. Satin papers should be hung over a *lining paper*. The paperhanger has to provide and hang materials required for covering damp walls.

2278*a*. Walls of rooms should *always be stripped* before the new paper be put up, a process

usually attempted to be shirked, even when charged in the estimate. In bad common plasterer's work, the setting coat often comes off in parts with the paper and has to be repaired. The walls are usually prepared for papering by a coat of *clearcole.*

SECT. XIII.

SPECIFICATIONS.

2279. The importance of an accurate specification or description of the materials and work to be used and performed in the execution of a building, is almost as great as the preparation of the designs for it. The frequent cost of works above the estimated sum, and its freedom from extra charges on winding up the accounts, will mainly depend on the clearness, fulness, and accuracy of the specifications; though it is but justice to the architect to state that extras arise almost as often from the caprice of his employer during the progress of the work, as from the neglect or carelessness of the architect in making the specification. A specification should be made in all cases of new designs, additions, or alterations in reference to designs, which, the more they are given in working drawings by the architect, the better will it be for his employer, no less than for the artificer.

2280. It is impossible to frame a set of directions which shall be applicable in all cases. What we here propose to do is, to give something like a list or skeleton of the component parts of buildings, from which the architect may select such as are suitable to the particular case whereon he may be engaged. We have not carried this into the repairs and alterations of houses, because, with difference of application, we apprehend what we are placing before the student will enable him to carry the system forward in such cases without any difficulty. The works of each artificer are as follow: —

2281. EXCAVATOR. To take down any old buildings and impediments that may be on the site of the new works. If any old materials are to be used again, he is to clean, sort, and stack them for re-using in such parts of the premises as may be directed. The rubbish, as well from these as from any superfluous earth that may come out of the basement and foundations, if not wanted for raising the ground or for other purposes, he is to cart away, either wholly, or to such part of the premises as may require it, on direction to that effect, as well as all rubbish that may accumulate in executing the works.

To dig out for basement story (where one is to be) for the foundations, areas, drains, floors, and all other works requisite. To beat down to a solid consistence the ground forming the beds of the trenches for receiving the foundations and walls, and after they are in, he is to fill in and ram down the ground with wooden rammers; to level, and to do such other rough groundwork as may be necessary for forming the sectional ground lines shown upon the drawings. In basements no earth is to be left nearer than 9 inches to any floor or other timbers, such cavities being by the specification to be filled in with dry lime core. And, finally, he is to leave the ground altogether free from all useless soil or other materials.

To bale out or pump out and remove all soil and water which may be necessary for laying the foundations, whether arising from springs, drains, cesspools, rain, or otherwise, and to be answerable for all accidental damage that may occur whilst the foundations and walls are carrying up, as also, when buildings adjoin, for all damage that may occur to neighbouring buildings.

2282. BRICKLAYER. The brickwork is to be executed with the very best hard well-burnt *grey stocks* (*or kiln-burnt red stock bricks, if the others are not to be had*), to be laid in flat joints, and so that every four courses shall not exceed 11½ inches in height.

When better bricks are used for *facing* external walls, they are to be specified as *best marle stocks, second marle stocks,* or *Suffolk white bricks,* as the case may be, in which case it must be specified that no headers of the facing are to be cut off, except where absolutely necessary to form good bond. Fronts so faced must be described to be either carried up with a neat flat parallel ruled joint, or to be afterwards tuck-joint pointed if a very finished face is wanted, though the latter is not altogether a very sound practice. In old work the joints may be described to be raked out, the brickwork washed, stained, and tuck-joint pointed.

No *place* or *samile* bricks to be allowed in any part of the work, under a penalty of two shillings for every such brick that may be detected to have been used.

The *mortar* is to be compounded of stone lime and sharp clean drift sand (if the work be of importance), to be ground in a pug-mill, or otherwise to be well tempered and beaten with wooden beaters, and to be in the proportion of one heaped bushel of lime to two of sand.

Bricklayer. (2282*a*.)

When the foundations are bad *concrete* should be provided, and is thus described: it is to be formed in the proportion of six parts of Thames or other unscreened clean ballast, and one part of fresh-burnt Dorking (or other) *stone* lime, beaten to powder on the premises, and unslaked. They are to be thoroughly mixed in small quantities at a time, the lime at mixing being slaked with as small a quantity of water as possible. The concrete, after mixing, is to be dropped from a stage to be formed by the contractor, so as to fall into the trench provided for its reception from a height of at least 12 feet. The thickness of the concrete thus executed may vary from 4 feet to 18 inches in height, according to the badness or goodness of the foundation.

English bond should be directed, and the work should be specified to be flushed up at every course with mortar. No bats to be allowed except for closures; and for sound work every fourth course to be *grouted* with liquid mortar, and in the foundations every course, or at least every second course. The walls, chimneys, their shafts and other works are to be carried up of the height and thicknesses and in the manner shown and figured on the several plans and drawings, together with all brickwork requisite for the completion of the house. If the architect prefers, he may particularise these, but the drawings will show his meaning better. When the work is within the metropolitan district, and not required to be of particularly great solidity it will be sufficient to describe that the thicknesses of the walls, their heights above the roofs, &c., shall be conformable to the regulations contained in the Building or other Act of the locality where one exists.

When the work is to appear without a stone or plaster facing, there must be described *rubbed* and *gauged arches* for all the external openings that will be seen in the principal fronts, of 9 or 14 inches in depth (or more according to their span), accurately cut, and set closely in front, in back, and on their sofites. To the other openings the arches are to be described plain arches, closely set; those which appear externally to be tuck-pointed on their outside faces. Over all lintels, too, in external walls, the specification should provide uncut accurately formed arches.

When *fascias* are formed of brick, they must be described with their projections, as also all cornices formed by the arrangements of bricks, whereof the heads may be required to show as modillions; but a drawing should, for the latter, always appear on the drawing or specification.

When the shafts of chimneys are carried up above the roof, out of the common way, they must be referred to drawings; otherwise what relates to them and their flues is merely described as follows: — *Turn*, *parget*, and *core* the chimney flues, and finish the shafts with salient courses 6 inches in height, with *double plaintile creesing* thereto, and for each flue provide and fix a large-sized chimney mould; the upper courses of the shafts above the creesing to be laid in Parker's cement. In most cases, now, the flues are covered with square chimney moulds, cast of Parker's cement, and may be described as plain or moulded, and otherwise ornamented.

When parapets are not to be coped with stone or cement, they must be described as finished with double plaintile creesing, and a brick on edge thereover, all laid in Parker's cement.

Generally, where weather is to be provided against in upper courses and elsewhere, the laying in Parker's cement must be described.

Turn *trimmers* of 4-inch brickwork to all the fire-places for receiving the hearths throughout the building, except where the hearths lie on ground in basement stories.

Where there are basement stories, or the story is on the ground. Describe piers 9 inches square, or continued walls 9 inches thick, to carry the sleepers whereon the joists of the floor or the courses of paving stone are to lie; in either case the cavity is to be filled, for at least 9 inches in height, with dry lime core.

Bed in mortar all bond timber, wall or other plates, lintels, wood bricks, templets, stone, or other work connected with the brickwork. All the door and window frames to be bedded in and pointed round with lime and hair mortar. Execute all requisite beam filling.

When the building is faced with stone, or stone dressings are used; to the above must be added — back up and fill in solid with brickwork all the stone work and iron work that is set in the brickwork.

If cornices, fascias, &c. are to be run in Parker's cement, or other sort of plaster, the instruction is — Prepare and fix brickwork, and such Yorkshire stone slabs and other materials as may be necessary for forming the several external cornices, pediments, strings, sills, and dressings to openings, in Parker's cement, or other cement, as the case may be, as shown on the drawings.

Turn arches in cement (if wanted) for carrying entrance or other steps. Provide all brickwork for stone steps. Turn vaults of brickwork (describe thickness not less

BRICKLAYER. (2282*b*.)

than 9 inches) over the intended cellars, according to the drawing, and properly cut all groins of intersections. The spandrels to be filled in with solid brickwork up to the level of the internal crown of the vaulting, the whole grouted with liquid mortar. When the centering is struck, the sofites of the vaultings are to be evenly and fairly cleaned off, and pointed.

Construct round the building a dry drain, as shown on the drawings, the top of the wall thereof to be level with the sections of the ground. Ram down the ground at the back thereof as the work is carried up, and provide such stone stays from the building as may be necessary for maintaining such wall in its place.

To execute proper barrel drains for draining the premises, as shown on the plans, to fall into a main sewer, or cesspool, as the case may be. The principal drains to be 1 ft. 6 in. and the smaller ones 12 inch barrelled drains, with half-brick rims, and the lower half of each drain composed with pure Parker's cement. At the foot of all rain-water, soil, and waste pipes, proper brick funnels are to be formed to lead down to the drain, the same to be constructed in Parker's cement. From all sink-stones funnels and drains to be formed to lead to the principal drains. N. B. We have here described the sizes of drains as for a moderate-sized mansion. We might say that 30 inches is the maximum diameter likely to be required for a large building, and none should be made less than 9 inches wide with half-brick sides, three courses high, curved top and bottom.

When a portico is designed, provide and execute walls for carrying the columns of portico, as shown on the plan, all piers or cross walls for receiving the landings, and brickwork to receive the steps. If the portico be of large size, describe discharging arches above the architrave in the space over intercolumniations, and from return columns to main walls. If a pediment, back up with brickwork behind the tympanum of pediment quite up to under side of raking cornice of pediment.

Wells, when above 6 feet in diameter, should be described to be steaned in a thickness of one brick, and when less than that size, in half a brick.

When water cannot be carried off to a public sewer or running stream, *cesspools* must be formed to receive it, and allow, if possible, its absorption by the earth. They are usually 3 feet 6 inches to 5 feet clear diameter, and are to be described as circular on plan, steaned round with hard stocks, in half a brick thick, laid dry till within 18 inches of the top, which 18 inches are to be laid in Parker's cement. If there be privies or water-closets far apart, each must be provided with a cesspool. Cesspools are sometimes domed over in brickwork, with a circular stone let into the eye or opening at the top of the dome; or they may be described to be covered with Yorkshire stone.

If any fence walls are required, their footings, thicknesses, heights, and lengths are to be mentioned, and of what bricks they are to be built. If any thing peculiar in their form, a section and elevation should be given.

Bricknogged partitions, which in practice ought, if possible, to be avoided, and are only to be justified where room is an object, are described as with bricks laid flat, or on edge, filled in between the quarters, ties, &c. of the partition.

Strong closets for plate or deeds require merely description of thickness of walls and brick arch, and usually 4-inch walls brought up for holding the requisite number of shelves. The same of wine cellars, whose bin walls must be mentioned.

Paving with bricks is described to be either of stocks, paving bricks, malm paviors, or clinkers, which may be laid flat or on edge in sand, mortar, or cement, and either straight-coursed or herring-bone.

Paving with tiles is usually in mortar; the tiles may be either 10 or 12 inches square.

All splays, ramps, and *chases* to be cut where wanted; the two former to be rubbed where necessary, and the latter to be pargetted

Brick ovens (one 10 feet wide and 8 feet 6 inches deep will bake twelve bushels of bread, and one 8 feet wide and 7 feet deep will bake eight bushels, and so in proportion) are to be constructed with Welsh lumps or fire bricks for fire-place, domed over, and hooped with iron hoops. The bricklayer is to provide the bars, plate door, bar to the archway of door, and other ironwork, and to carry up a proper flue from the fire.

Iron ovens. The bricklayer is to set in proper brickwork an iron oven capable of baking two bushels of bread.

Coppers and stewing stoves to be set neatly in brickwork, the latter in guaged brickwork with tile top, and proper flues carried up therefrom.

Columns to porticoes or fronts which are to be coated with cement must be described of such diameters as the drawings for finishing require, with entablature, &c., as the case may be, carried up in Parker's cement.

In describing stables, besides what may be applicable from the foregoing directions, two *air-flues* are to be constructed to each stall and loose box, 9 inches square, and

Bricklayer. (2282c.)

carried up over the racks within the thickness of the brickwork, communicating at their tops with the external air by curved tops to secure them from the penetration of the rain. *Dung-pit walls*, whose dimensions depend on the size of the stables. *Lime white* walls of stables.

If roofs are covered with tiles, either pan or plain. The description for the former will be either laid dry, or bedded in lime and hair, or pointed outside or inside, or on both sides; or if glazed pantiling, to be so described, laid to a 10-inch gauge on stout fir laths, with hip, ridge, and valley tiles, filleting cutting to splays, beam filling, painted T nails, hip hooks, &c. *Plain tiling* is described as laid to a close guage on heart of oak double laths, with all the plaintiles pegged. The hip and ridge tiles to be set in Parker's cement, with T nails dipped in melted hot pitch in all the joints. Strong, similarly pitched, wrought iron hip hooks. Filletings of Parker's cement, with strong cast iron nails for forming a key driven into the walls or other brickwork at intervals, close enough to secure the same.

In cases of underpinning the bricklayer is to cut all holes for the needles, and to remove the old work, and to bring up the work in Parker's cement on concrete foundation; and, finally, drive the cast iron wedges for bringing the work to a solid bearing.

Where inverted arches are used in foundations they must be shown on the drawings.

Provide, according to the extent of the job, a certain number of rods of brickwork for such extras as may be ordered by the architect; and if the whole or any part thereof should not be wanted, a deduction to be made on settling the accounts for so much thereof as shall not have been used, at a price per rod to be named.

To build all the walls level, except otherwise directed; to be answerable for all damage that may occur to the work, by settlements or otherwise, during the time of building, and to make good the same as the architect shall direct; and, further, to perform all such jobbing work as shall be necessary for completely finishing the building. To provide good sound and sufficient scaffolding, which is to remain for the use of the mason, carpenter, and other artificers that may have occasion to use the same.

To pay the proper fees to the district, sewer, and paving surveyors, and to give the necessary notices and obtain the proper licences in their departments for executing the works. This now applies in many towns besides London, under Local Acts.

2283. Slater. To cover the roofs with the best strong Westmoreland, Tavistock, Welsh rag, imperial, queen, duchess, countess, ladies, or double slating, (as the architect may think most appropriate, each being named in the order of the value and quality,) securely fixed with best strong copper nails. Every part to be properly bonded, especially at the eaves and heading courses thereof, with slates cut to keep the bond uniform. No slates to be laid lengthwise.

Fillets against the brickwork, where requisite, of Parker's cement; such fillets to be formed with nails driven at proper intervals to form a hold for the cement (where lead step flashings are intended the fillets need not be described). Fillets of brick or stone may be built up with the wall, level or raking; and if they should be preferred by the architect, they must be described in the bricklayer's or mason's works.

All the slating is to be rendered up perfect on completing the building, and all jobbing work to be performed that may become necessary as the work is carried on.

If the slating is required to be rendered as air-tight as possible, it must be described to be pointed on the inside with stone lime mortar, with a proper quantity of hair therein; but the pointing of either slates or tiles, from the constant expansion and contraction arising from heat and cold, soon falls out and becomes useless. Slater to be answerable twelve months for his work.

If slate skirtings and cisterns are intended about the building, they must be described, as also sinks, steps, and other modern applications of the material.

2284. Mason. The stone to be used in a building generally depends of course on the place where it is to be built, unless, without regard to expense, the employer determines on the use of any particular sort; in which case the account of the different quarries of the provinces, given in Chap. II. Section II. of this Book, will furnish the architect with the means of describing the best of its sort. For the choice, therefore, where it is left to the architect to decide, we must refer him to that account. In the neighbourhood of London that from the island of Portland is most used. Granite is chiefly used where great strains and pressures occur, or where wear and tear and the action of the weather indicate its employment.

Having described the sort of stone selected to be of the best quality, free from all vents, shakes, &c., the next direction is, that it shall be throughout laid in the direc-

MASON. (2284a.)

tion of its natural bed in the quarry; and if the whole building is of stone, many of the following particulars will be unnecessary,—which of them will immediately speak for themselves. Where the building is only faced with stone, the specification will run as follows:—The . . . fronts (describing them) are to be faced with Portland (or other, as the case may be) stone ashlaring in courses to fall in with the courses of brickwork, carried up after the manner of Flemish bond. The stretchers of such ashlaring being 4½ inches deep and the headers 9 inches, with bond stones running through the whole thickness of the wall in the proportion of $\frac{1}{18}$ of the face, to be introduced where the piers allow. No quoins to show a thickness of less than 12 inches. The whole to be cramped with cramps to the satisfaction of the architect, the mason finding the same, and properly running them with lead.

In cases where the building is of brick with stone dressings, the specification will run thus:—To provide and set a Portland stone (or other stone or granite) plinth all round (or part, as the case may be) the building, . . . feet . . . inches high and 8½ thick, in stones not less than 3 feet in length, the vertical joints to be cramped with T cramps not less than 12 inches long. Describe whether joints are to be close or channelled, and whether ashlar is to be rusticked (rockworked). To provide and fix at the angles of the building, as shown upon the drawings, solid quoins of Portland (or other, as the case may be) stone [here describe whether close, chamfered, or channelled joints, and whether rusticked (rockworked)] of the length and height shown.

To provide and fix, as shown, string courses, scantling . . . inches by . . . . inches, throated and bevelled on the upper face, and the joints plugged with lead.

To provide and fix, as shown on the drawings, a cornice and blocking course, scantling . . . by . . . , moulded according to the drawings, the bed to be such that the weight of each block of stone in the projecting part shall not be equal to that on the bed by one fourth of its cubic contents. The same to be executed according to the drawings; to have proper sunk water joints, and to be channelled and plugged with lead at all the joints.

Blocking course, as shown on the drawings, . . . inches high, . . . thick on the bed, and . . . on the top, plugged with lead at all the joints, with solid block at the quoins returned at least 24 inches.

Balustrades (if any) to be provided of the heights and sizes shown on the drawings and section thereof. The balusters to be wrought out of stone, allowing at least 1 inch of joggle at their ends into the plinth and impost. All the vertical joints to be well plugged with lead; the impost to be cramped with cast iron (or bell metal), and the whole to be securely fixed. The half balusters to be worked out of the same block of stone as their adjoining pedestal.

Columns and pilasters (if any), with pedestals, capitals, bases, plinths, &c., and entablature, to be provided and fixed as shown on the drawings. The columns and pilasters not to be in courses of more than . . . blocks of stone. The architraves to be joggled from those resting on the columns or pilasters themselves, and these as well as the frieze and cornice to break joint over the architrave. The architraves, if blocks of stone can be supplied large enough, to be in one block from centre to centre of column, with return architraves in like manner. The whole of the entablature (as well as the pediment, if any) to be executed with all requisite joggles and cramps (and if a pediment be projected, the apex to be in one stone) as shall be approved by the architect. The pilasters (if any) to be bonded not less than . . . inches into the wall, against which they are placed in every other course. The sofites of the portico to be, as shown on the plan and sections, formed into panels and ornamented. Provide and let into the top of the architrave good and sufficient chain bars, with stubs on the under side for letting into every stone composing the architrave.

If the portico be very large, it is not necessary to make the frieze solid, but concealed arches should be turned in the space from column to column to support the superincumbent weight of the cornice and pediment. If the columns are fluted, it must be mentioned.

When a pediment, the tympanum may be described to be faced with ashlaring.

To construct and fix dressings and sills to the external windows and doors, as shown on the drawings, with all such throated, sunk, moulded, carved, rebated, and other works as may be necessary.

If a portico is shown, to provide and fix of solid . . . stone . . . steps round the portico scantling . . . by . . . , properly back-jointed and worked all over; and within the portico to provide and fix a complete landing of stone, at least 4 inches thick (or less, if a small portico), in slabs, as shown. The joints of the steps and landings are to be joggled and run with lead.

Mason. (2284*b*.)

All ornaments, carving, enrichment of capitals, of columns and pilasters, and of such as may be shown in the entablature, is to be executed in an artist-like good style. Models from the working drawings are to be made at the contractor's expense, and the whole to be executed to the satisfaction of the architect.

The order may be described if the working drawings are not sufficiently made out.

Provide and fix plinths and base mouldings to the portico, as shown on the drawings, to be worked out of (describe stone) . . . stone of . . . by . . . scantling.

Finish the chimney shafts with mouldings as shown in the drawings, or with sunk moulded and throated copings, . . . inches wide and . . . inches thick.

To describe sills generally, take the following: —

Sills to . . . windows of Portland stone, 9½ by 6 inches.

Sills to . . . windows moulded and of Portland stone, 14 by 8 inches.

Sills to . . . windows of Aberdeen granite, finely tooled, scantling 14 inches by 9 inches.

Sills to . . . windows of Portland stone, 9 by 5 inches.

All window sills are to be properly sunk, weathered, and throated, and at each end to be 4 inches longer than the opening.

To provide and lay to all the walls Yorkshire stone 3 inches thick and 4 inches on each side wider than the several lowest footings, in slabs of one length across the width of the footing.

If balconies to a house, describe thus: — A balcony landing of Portland stone . . . . inches thick, moulded on the edges and the pieces joggled together, and run with lead, to be provided with holes cut therein for the iron railing. The said balcony is to be tailed into the wall, and securely pinned up.

Steps to doorways must be described as to scantlings. All external steps should be weathered.

Where story posts are used in a front, it is well to place along the front two pieces of parallel square Aberdeen or other good granite curb scantling, 12 inches by 9 inches, cut out to receive the bases of the columns and story posts.

For a back staircase, carry up and construct a staircase from the basement to the principal floor, with solid Yorkshire quarry steps 13 inches wide and 6½ inches high, properly back-jointed and pinned into the brickwork; cut holes for the iron balustres. N. B. This sort of staircase of Portland will serve also for back stairs of upper flights. That from the basement may also be made of granite street curb, 12 by 7 or 8 inches. A staircase may, for cheapness, be made of Yorkshire stone paving 3 inches thick, wrought with fair tooled edges, and securely pinned into the brickwork.

Principal stairs to be of Portland stone (as may be), to extend from principal to . . . floor, with steps and square (or semicircular, as may be) landings, entirely of solid stone, tailed 9 inches into the brickwork, with moulded nosings and returned nosings, and also at the back. The sofites to be moulded to the shapes of the ends of the steps. The landings to be 6 inches thick, with moulded nosings and joggled joints, run with lead, to be inserted at least 4 inches in the walls, but such as tail into the walls, as steps, must go at least 9 inches into the walls.

When the under sides of the steps of the geometrical staircase are not moulded, the nosings are returned so as to fall beyond the upright line of the succeeding tread; in this case the sofite or string is plain wrought.

Pave the entrance hall and principal staircase, together with (any apartments wished) with the best . . . marble, and border according to the pattern drawn.

The back staircase (and such other parts as require it) is to be paved with Portland stone 2 inches thick, laid in squares, and with a border 8 inches square.

Dairy, if any, to be paved with . . . . stone, in regular courses . . . . inches thick. Provide a shelf or dresser round the said dairy of veined marble 1 inch thick, and a skirting round it 6 inches high. The dresser to go into the wall 1 inch, and to be supported on veined marble piers 4 inches square.

Pave the scullery, larder, pantry, passages, lobbies (and such other places as may require mention), with rubbed Yorkshire stone 2½ inches thick, laid in regular courses with close rubbed joints.

Pave the bottom of the air drain with Yorkshire paving.

Yards may be paved with 2½-inch Yorkshire paving, or such other as the place affords, as in common use. The same to basement stories.

To fit up the wine cellar with bins, as per drawing, with 3-inch Yorkshire stone shelves (some prefer slate), fairly tooled, and set in Parker's cement.

To provide and fix a warm bath of veined marble; rendered waterproof by being properly set in Dutch tarras, and plugged and cramped with copper at the joints, with all requisite finishing. A marble step round two sides of the bath. Cut all holes

MASON. (2284c.)

necessary for laying on the water. A bath may be similarly made of slate, which is of course much cheaper.

Where iron girders are used, describe . . . . pieces of granite street curb, each . . . . feet long, to receive the ends of the cast iron girders.

Where chimneys project without support from below, corbels must be described proportioned to the weight they have to carry. The best corbel, however, is the gradual projection of the work by inverted steps, which, if there be height to hide them, should always be the mode of execution.

Cellar doorways should have in each of them three pieces of Portland or other such stone, 18 inches wide, 18 inches long, and 9 inches high, cut out to receive the hinges and also the rim of the lock.

All fire-places should have back hearths of 2½-inch rubbed Yorkshire stone.

The commonest chimney-pieces that can be described are of 1½-inch Portland stone jambs, mantels, and shelves, 6 inches wide; with slabs of 2-inch Portland stone, 24 inches wide, and 6 inches or a foot wider on each side than the width of the opening

For those of butler's and housekeeper's rooms drawings are usually given.

A kitchen chimney is described as jambs and mantel (in one piece) of 2-inch Portland stone, 10 (or 12) inches wide, with a slab of 2½-inch rubbed Yorkshire stone, if used with a wood floor; but sometimes the whole width of that side of the kitchen is paved.

For the several rooms where marble chimney-pieces are to be placed, chimney-pieces are described to be provided of a given value, varying in the less important to the best apartments, from eight or ten up to 100 guineas or more in value, of such marble as the employer may select: but if the working drawings have been fully prepared, this is a matter which need not be left in uncertainty. It must always be provided in the specification that the slabs are included, and that the price is or is not (as the case may be) to include the carriage and fixing.

Sinks of Portland or other stones, 7 inches thick (describing the size required), to be provided and fixed as shown in the drawings, with holes cut for the grating and socket-pipe, and fixed with all requisite bearers or supports, complete.

Sink stones to drains to be provided where shown on the plan.

The joints of the masonry generally are to be where exhibited on the drawings, and the work is to be left perfectly cleaned off, all necessary joggles, joints, rebates, moulded, sunk, weathered and throated works, grooves, chases, holes, back joints, and fair edges, that may be necessary in any part of the work, and all jobbing, though not particularly mentioned under the several heads, is to be performed that may be requisite for the execution of the building, and all the work is to be well cleaned off before delivering it up. The whole of the work is to be warranted perfect, and any damage that may occur to it by reason of frost or settlement within two years after the completion of the building is to be repaired, under the architect's direction, at the sole expense of the contractor.

All mortar is to be of the same quality as that described in the bricklayer's work.

The contractor is to provide lead to run the cramps and joints.

In works within the metropolitan district, the contractor is to pay the expense, under the commissioners of sewers or paving, as the case may be, of making good the street paving to the areas, plinths, and steps abutting thereon.

To provide and fix under the contract . . . . cubic feet of . . . . stone, including plain work and setting thereto, also . . . . superficial feet of 2½-inch Yorkshire paving, laid in regular courses; and in case the whole or any part of either or both should not be wanted, the quantity not used or directed shall be deducted from the amount of the consideration of the contract after the rate of . . . . per foot of cubic stone and . . . . per foot superficial for the Yorkshire paving, including the workmanship and fixing thereof.

In stables, granite should be provided to receive the heel-posts if cast iron be not employed, and at the piers of gates, hinge and spur stones, the latter, of granite, if to be had, should be described. The caps and bases of the last can be described only with reference to the drawings of them.

The paving of stables and their courts is described thus: Prepare the ground for paving (stating where) with good and sufficient hard materials, and pave it with Aberdeen granite paving, properly dressed and sorted, 8 inches deep and 5 inches wide at the top and bottom thereof. The whole to be laid with good currents upon a layer 4 inches at least in thickness of good rough gravel, the joints of the surface to be run with stone lime and river sand grouting. It is to be well rammed, and the contractor is to relay, at his own expense, all such parts as may sink within eighteen months of the work being completed.

Where the work is within the metropolitan district, or within a town, a sufficient hoarding must be erected for enclosing the premises during the execution of the

Mason. (2284*d*.)

works, which is to be removed and carried away when they are complete. So, also, all shoring is to be provided, if the works be alterations, or the adjoining buildings may be injured by carrying them into effect. The shoring is to be performed in a safe, scientific, and workmanlike manner, of the fronts, floors, or otherwise, as the case may be.

2285. Carpenter and Joiner. Where the extent of the works requires a clerk of the works: a direction must be given to provide, erect, and maintain, during their performance, a temporary office for the clerk of the works, with all appurtenances complete, with stool, table, and all other requisite furniture.

All materials requisite for completion of the buildings according to the drawings are to be provided by the contractor. The oak is to be of English growth; the timber not specified of oak is to be of the best Dantzic, Riga, or Memel yellow fir. No American, Swedish, or Scotch fir to be used in any part of the building. All the floors and joiner's work are, except where otherwise directed, to be of the best Christiana deals. The timbers and deals are to be cut square, entirely free from sapwood, shakes, large knots, and all other defects. If any part or parts of the joiner's work should shrink or fly within eighteen months from the finishing and fixing the same, the contractor is to take down, refix, and make good the same, together with all works that may be affected thereby, at his own expense.

No joists, rafters, or quarters are in any case, unless particularly so directed, to be more than 12 inches clear distance from one another.

To provide and fix, ease, and strike all centering and turning pieces for the vaults, arches, trimmers, and other works. Provide all temporary shores that may be necessary. Fix all iron-work of every description. Provide and fix all necessary templets, linings, blocks, stops, casings, beads, springing fillets, angle staffs, grounds, linings, backings, furrings, cappings, and other finishings incident to carpenters' and joiners' works, together with all necessary grooving, rebating, framing, tonguing, housing, beading, mitring, framing, and other workmanship necessary for completing the works.

To provide good and secure casing for all the stone dressings, to protect the same from injury during the execution of the works; and any accident arising from neglect in this respect is to be made good at the expense of the carpenter.

Bond timber. One tier is generally enough for basement story.
Two tiers in the other floors, unless very lofty.
One tier in the upper story.

4 inches by 2½ inches all around the walls, except where intercepted by the chimneys, to be lapped together, where joints occur, at least 6 inches, and to be properly spiked together. Party walls may be bonded with iron hooping, if thought proper, for a greater security against fire.

To find and fix all wood bricks for fixing the finishings to.

Provide and fix all lintels, and filling in lintels that may be necessary to the several openings: each to be 4 inches high, of the width of the brick work, and 16 inches longer than the opening.

Two small lintels will do if the width of the sofite be considerable, and arches as directed in the bricklayer's work be turned.

For ground or rather basement floors, walls are brought up for receiving oak sleepers, 5 by 3 inches; on which fir joists 4½ by 2½ are generally the scantlings employed.

For other floors. Wall plates 6 by 4 are described.

Girders - - -
Joists of all descriptions, according to the kind of floor -
Trimmers and trimming joists

} All which, with their requisite scantlings, will be found in Practical Carpentry. (2013, *et seq.*)

Cradling to the girders and such parts as may be necessary to form panels and coffers on the under side for the ceiling, if such be practised.

Where it is necessary to truss the girders, that must be stated.

Cock down all girders on the wall plates. Pin bridging joists to binders with ¾-inch oak pins.

For roofs, wall plates should be at least 6 inches by 6 inches.

For the different timbers of the several sorts of roofs, the reader will refer to the section on Practical Carpentry, where they are described, and scantlings given of works that have been executed. (2027, *et seq.*) Ceiling joists also to be described.

To what is there found, we may add, that hips and ridges rounded for lead ought to be 10 by 2.

Carpenter and Joiner. (2285*a*.)

Where close boarding is used, it should not be less than ¾ to an inch thick. If battens for slating, they should be 2½ inches wide; the first should be nailed with eightpenny nails. Provide lear boards.

We prefer, on many accounts, and, indeed, ourselves usually adopt, the Italian method of laying the rafters horizontally as so many purlines. For the boarding not lying lengthwise towards the gable, any wet that may find its way on to it from defective slates or lead, is not apt to lodge against and rot the edges.

Flats are described with wall plates usually 6 by 6. Trimmers and trimming joists against chimneys, and where skylights occur; and 1¼ inch yellow deal boarding, listed, free from sapwood, laid with a current of 1½-inch to 10 feet lineal, with 2½ drips to heading joints, of lead rolls to longitudinal joints, and inch yellow deal risers not less than 4 inches wide next the gutter

Gutters to the roof or roofs are to be as shown on the plan, with inch yellow deal bottoms on strong fir bearers, and laid with a current of 1½ inches to every 10 feet; 2½ rebated drips, and at the sides to have ¾-inch deal lear boards, 9 inches wide. Gutter boards are rarely more than 1¼ inch thick.

Gutter plates, if any, to be described, but they should never be used without support from below.

Trim for trap doors, if any, leading to the roof, and provide and fix dormers with all necessary framing.

Cheeks, doors, beaded stops and linings, and ironmongery. Boarding for slating or lead to top and cheeks, as the case may be.

Dormers may be similarly described for windows in the roof.

Quartered partitions, where shown on the plan, with heads and sills 4 inches by 4 inches. Ties above the doors 4 inches by 5 inches. Posts 4 inches by 3½ inches. Braces or struts 3 inches square. Quarters 4 inches by 2 inches, and three tiers of interties, 1 inch by 2½ inches. In cases where partitions are to be trussed for carrying either their own or some additional weight, reference must be made to drawings.

To put to . . . . floors (or to the whole if desired) *sounding boarding* of ¾-inch rough deal, fixed upon fillets, to receive the *pugging*. (See 2287*a*.)

All external walls should be described to be battened. The thickness of the battens is usually from ¾-inch to 1¼-inch, their widths 2½ inches, and they are placed from 7 to 12 inches apart. If no bond timber to nail them to, plugs must be let into the walls.

Bracketing and cradling is usually, for cornices, coves, &c., 1¼ inch thick; for entablatures, circular sofites, and waggon-headed ceilings, 1½ to 2 inches thick.

All bearers to be fixed and provided as shall be necessary.

Weather boarding is usually described as ¾ inch or 6 boards to a 3-inch yellow deal, wrought, or wrought and beaded; or as 1-inch or 4 boards to a 3-inch deal.

Luffer boarding ought to be of 1-inch deal, wrought two sides and splayed.

Warehouse posts must be described with their relation to the weight they are to carry (see Beams and Pillars, 1635. *et seq.*), the caps to them should be long, so that they may not press into the girders, and, if practicable, iron dowels should pass through the girders to catch the bases of the posts in the floor above.

In ordinary cases fir story posts are about 9 inches square. Oak caps, 3 feet long, with splayed ends 9 by 6. Floors are usually rough, not less than 1½-inch deal rebated.

Water trunks are made of sizes from 4 to 6 inches or more square, of ¾ inch to 1¼-inch deal. They are always to be described as pitched and fixed complete, with hopper heads and shoes, wall hooks, holdfasts, &c.

Park paling is of the following varieties, and must be described accordingly: —

4-feet oak cleft pales, 2 arris rails and oak posts.
5-feet oak cleft pales, 2 arris rails and oak posts.
6-feet oak cleft pales, 3 arris rails and oak posts.

If there is to be an oak plank at the bottom, and oak capping at top, they must be specially mentioned.

To provide and fix . . . cubic feet of Baltic yellow fir timber, with all labour thereto, beyond the quantity necessary for the work herein described, to be used in such additional works as may be directed by the architect; and if the whole or any part thereof should not be ordered, the same shall be deducted from the amount of the consideration of the contract, after the rate of . . . per foot cube. All additional fir, if any should be ordered, is to be taken at the like price of . . . per foot cube.

The varieties of *floors* are as follow, each set of thicknesses being enumerated in the order of their increasing value. Batten floors are for better rooms.

CARPENTER AND JOINER. (2285*b*.)

¾-inch *white* deal, rough, with edges shot.
¾-inch *white* deal, wrought, and laid folding.
¾-inch *yellow* deal, rough, with edges shot.
¾-inch *yellow* deal, wrought, and laid folding.
¾-inch *white* deal batten floor, wrought, and laid folding.
¾-inch *yellow* deal batten floor, wrought, and laid folding.
1-inch *white* deal, rough edges shot.
1-inch *white* deal, wrought, and laid folding.
1-inch *white* deal, wrought, and laid straight joint and splayed headings.
1-inch *yellow* deal, rough edges shot.
1-inch *yellow* deal, wrought, and laid folding.
1-inch *yellow* deal, wrought, and laid straight joint and splayed headings.
1-inch *white* deal batten floor, wrought, and laid folding.
1-inch *white* deal batten floor, wrought, and laid straight joint and splayed headings.
1-inch *yellow* deal batten floor, wrought, and laid folding.
1-inch *yellow* deal batten floor, wrought, and laid straight joint and splayed headings.
1¼-inch *white* deal, rough edges shot.
1¼-inch *white* deal, wrought, and laid folding.
1¼-inch *white* deal, wrought, straight joint, and splayed headings.
1¼-inch *yellow* deal, rough edges shot.
1¼-inch *yellow* deal, wrought, and laid folding.
1¼-inch *yellow* deal, wrought, straight joint, and splayed headings.
1¼-inch *white* deal batten floor, straight joint, and splayed headings.
1¼-inch *white* deal batten floor, straight joint edge nailed, and splayed headings.
1¼-inch *yellow* deal batten floor, straight joint, and splayed headings.
1¼-inch *yellow* deal batten floor, straight joint, edge nailed, and tongued headings.
1¼-inch *white* deal batten floor, edge nailed, and tongued headings.
1¼-inch *yellow* deal batten floor, edge nailed, and tongued headings.
1¼-inch *yellow* deal batten floor, dowelled with oak dowels, with mitred and glued borders.
1¼-inch *yellow* deal, clean batten floor, dowelled with oak dowels, with mitred and glued borders.

Warehouse floors are of
1½-inch *yellow* deal, rough edges shot.
1½-inch *yellow* deal, wrought, and laid folding.
1½-inch *yellow* deal, wrought, and straight joint, and splayed headings
2-inch *yellow* deal, rough edges shot
2-inch *yellow* deal, wrought, and laid folding.
2-inch *yellow* deal, wrought, and laid straight joint and splayed headings.
All these last may be ploughed, rebated, and feather-tongued.

The floors of inlaid or *parquetry* work must form, when to be provided, special subjects of specification; they must be described according to drawings, on which are to be marked the different woods to be used in their formation.

The varieties of *skirtings* are classed as under, beginning with the commonest sort: —
½-inch deal square skirting.
¾-inch deal square skirting.
¾-inch deal torus skirting.
1-inch deal square skirting.
1-inch deal square skirting, rebated and backed plinth, with fillet nailed to floor.
1-inch deal torus skirting.
1¼-inch deal square skirting.
1¼-inch deal torus skirting.
1¼-inch deal torus skirting, rebated and backed plinth, with fillet nailed to floor.

If any of these, as to stairs for instance, are raking, and to be scribed to steps, they must be so described, and so if any of them are to be ramped, and similarly if they are to be scribed to moulded nosings, as also if they be circular on the plan.

Dados in their varieties are as follow, premising that they are nailed to grounds which should be mentioned.
¾-inch deal keyed.
1-inch deal keyed.
1¼-inch deal keyed.
1¼-inch deal keyed, ploughed and tongued.
1¼-inch deal keyed, feather-tongued.

CARPENTER AND JOINER. (2285c.)

Scribed to steps, circular on plan, and wreathed, or ramped: those matters must be mentioned.

Of *wainscotting* with fascia and skirting, the different kinds are subjoined in the order of their quality.

1-inch deal, square framed
1-inch deal, square framed dwarf
1¼-inch deal, square framed
1¼-inch deal, square framed, dwarf
1¼-inch deal, bead butt or moulded
1¼-inch deal, bead butt
1¼-inch deal, bead flush

} The number of panels high to be specified.

When any of these are raking, or to have a beaded or moulded capping, or both or either, such must be specified.

Partitions of deal for the division of rooms are only used in taverns and the like; but where they are wanted, as for a mere separation in servants' rooms, they may be employed. Their varieties are —

1-inch deal board, and braced with ½-inch panels.
1¼-inch deal, braced with ¾-inch panels.
1¼-inch deal, rough, and ledged edges shot.

} These are scarcely to be employed.

1¼-inch deal, wrought both sides, and ploughed.
1¼-inch deal, wrought both sides, tongued, and beaded.
1¼-inch, square framed.
1¼-inch, square framed.
1½-inch, bead butt, moulded and square.
1½-inch, bead flush and square.
1½-inch, moulded on both sides.
2-inch, square framed.
2-inch, bead butt or moulded and square.
2-inch, bead flush and square.
2-inch, moulded on both sides.
2-inch, moulded and bead flush.
2-inch, bead flush and bead butt.
2-inch, bead flush on both sides.

These, as well as any preceding and following parts of a specification, will, of course, have reference to what is wanted in the design which it is the architect's object to describe in such specification.

Grounds. — We have mentioned grounds generally (2166.); but it may be as well here to insert their several sorts: for instance, —

Those of ¾-inch deal, of 1-inch deal, of 1¼-inch deal, of 1½-inch deal, and whether circular; also 1-inch, 1¼-inch, and 1½-inch skeleton grounds, which it is, perhaps, for security against extras, as well to repeat.

Door cases are usually employed on basement stories, and should be of oak, though fir is constantly used for them. They fit into the brickwork, and are usually about 5 by 5 inches, and they should be tenoned (the tenon being well pitched or set in white lead) into the stone step, on which they ought to be placed; for the sill, into which it is the practice to place them, soon rots, however good the material.

Door linings and their sofites. — These are either plain or framed, the former being of the commoner sort, and the latter for better work and places. They may be enumerated as follow: —

1-inch deal, single rebated.
1-inch deal, double rebated (that is, so that the door may hang on either side).
1¼-inch deal, single rebated.
1¼-inch deal, double rebated.
1½-inch deal, single rebated.
1½-inch deal, double rebated.

Either of the foregoing, if to be beaded on the edge, must be so described. Of framed linings and sofites for doors there are —

1¼-inch, square framed in one panel and double rebated.
1¼-inch, square framed in one panel and double rebated, bead butt or moulded.
1¼-inch, square framed in one panel and double rebated, bead flush.
1½-inch, square framed in one panel and double rebated.
1½-inch, square framed in one panel and double rebated, bead butt, or moulded.
1½-inch, square framed in one panel and double rebated, bead flush.

If the panels in the linings are to be raised, to correspond with panels of doors, they must be so described.

CARPENTER AND JOINER. (2285*d*)

Framed back linings are as follow: —

1-inch deal, two panel square.
1-inch deal, two panel square, bead butt.
1-inch deal, three panel square.
1-inch deal, three panel square, bead butt.
1-inch deal, four panel square.
1-inch deal, four panel square, bead butt.

If there be more than four panels, or they are splayed on the plan, or if bead flush, or of a greater thickness, they must be so specified.

Backs, elbows, and *sofites* to windows are described as —

1-inch deal, keyed.
1-inch deal, keyed, framed square.
1¼-inch deal, framed square.
1¼-inch deal, framed square, moulded, or bead butt.
1¼-inch deal, framed square, bead flush.
1¼-inch deal, square framed sofite, with one edge circular. } Applicable to bay win-
1¼-inch deal, square framed sofite, with two edges circular. } dows.
1¼-inch deal, square framed sofite, moulded, or bead butt.
1½-inch deal, framed square.
1½-inch deal, framed square, moulded, or bead butt.
1½-inch deal, framed square, moulded, or bead flush.

If any of these are splayed, fancy moulded, and with cappings, when also they are circular on the plan, they must be so particularly specified, inasmuch as the price is thereby enhanced.

Boxings for shutters are of the following varieties: —

1-inch deal, splayed boxings.
1-inch deal, proper boxings.
1¼-inch deal, splayed boxings.
1¼-inch deal, proper boxings.
1¼-inch deal, boxings with circular head.
1-inch deal, boxings for sliding shutters, with pulley pieces, beads, fillets, and grooves, complete.
1¼-inch deal, boxings for sliding shutters, with pulley pieces, beads, fillets, and grooves, complete.

These, if to be double hung, must be so described.

Window shutters. — As in the foregoing parts of a specification, we shall proceed from the common to the better sorts.

¾-inch deal, ledged or clamped.
¾-inch deal, ledged, or clamped, in two heights.
1-inch deal, clamped.
1-inch deal, clamped in two heights.
1-inch deal, clamped in two heights, one panel, bead butt, and square.
1-inch deal, clamped in two heights, one panel, bead flush, and square.
1-inch deal, clamped in two heights, one panel, bead flush, and bead butt.
1¼-inch deal, two panels square.
1¼-inch deal, two panels square, in two heights.
1¼-inch deal, two panels square, in two heights, moulded, or bead butt, and square.
1¼-inch deal, two panels square, in two heights, bead flush, and square.
1¼-inch deal, two panels square, in two heights, bead flush, and bead butt.

These may be described of 1¼-inch deal; but the back flaps need not be more than one inch, and the additional panels in height, projecting mouldings, if any, and other variations from the general description, must be mentioned.

Sliding shutters are to be described in their varieties, as follow: —

1-inch deal, two panels square, hung with lines and weights.
1¼-inch deal, two panels square, hung with lines and weights.
1¼-inch deal, bead butt and square, hung with lines and weights.
1¼-inch deal, bead flush and square, hung with lines and weights.
1¼-inch deal, bead butt and moulded, hung with lines and weights.
1¼-inch deal, bead flush and bead butt, hung with lines and weights.

These, if of 1¼-inch deal, and if more panels in height, must be so described; so also if they are circular on the plan; and if patent lines are to be used for the hanging, they must be mentioned.

Outside shutters, now rarely used, even in the provinces, except for shop fronts, must be mentioned, to make our description complete; they are of

1¼-inch deal, three panels, bead butt and square.
1¼-inch deal, three panels bead flush and square.

CARPENTER AND JOINER. (2285*e*)

1¼-inch deal, three panels, bead flush and bead butt.
1¼-inch deal, three panels, bead flush on both sides.
1¼-inch deal, three panels, bead butt and square.
1¼-inch deal, three panels, bead flush and square.
1¼-inch deal, three panels, bead flush and bead butt.

If these are circular on the plan, or contain more than three panels in height, the specification must so state.

Staircases are described as under, beginning with the commonest.

1-inch yellow deal, steps, risers, and carriages.
1¼-inch deal, steps, inch risers, and carriage.
1¼-inch deal, steps and risers glued up and blocked to close string moulded nosings, and two fir carriages.
1¼-inch deal, steps and risers mitred to cut string, and dovetailed to balusters.
1¼-inch deal, steps to winders, mitred to cut string, and dovetailed to balusters, one end circular.
1¼-inch deal, steps to winders, mitred to cut string, and dovetailed to balusters, both ends circular.

If the risers are to be tongued to the steps, if feather jointed, or if of clean deal, such must be stated in the specification.

1¼-inch deal, wrought steps, risers, and strong carriage.
2-inch deal, wrought steps, risers, and strong carriage.
1¼-inch oak, treads and risers mitred to string and dovetailed with fir carriage (with solid quarter ends to steps if required), also curtailed step and riser (2187, *et seq.*), returned moulded and mitred nosings, circular, if necessary, with cut plain (and circular) brackets.

Housings to ends of steps and winders, and the same to moulded nosings and circular ends, are to be specified.

String boards to staircases to receive the ceilings of stairs (or strings as they are called), are—

1-inch deal, framed.
1-inch deal, framed, rebated, and beaded.
1¼-inch deal, framed string board.
1¼-inch deal, framed string board, sunk and beaded.
1¼-inch deal, framed string board, sunk, beaded, and moulded.
1¼-inch deal, framed string board, sunk, beaded, moulded, and mitred to risers.
1¼-inch deal, wreathed outside, string glued upright, rebated, and beaded.
1¼-inch deal, wreathed outside, string glued upright, rebated, beaded, and sunk.
1¼-inch deal, wreathed outside, string glued upright, rebated, beaded, sunk, and moulded.

If the string is to be glued up in thicknesses, that must be specified, as also all plain or moulded circular cuttings or ramps.

1-inch deal, plain wall string.
1¼-inch deal, plain wall string.
1¼-inch deal, plain wall string.
2-inch deal, plain wall string.

If moulded, to be so described.

Handrails to staircases are described as—

1¼-inch deal, plain wreathed.
1¼-inch deal, plain wreathed.
2-inch deal, plain wreathed.

If moulded, state so.

Deal moulded 2¼-inch handrail.
Deal moulded 2¼-inch handrail, ramped (or circular where required).
Deal moulded 2¼-inch handrail, wreathed and twisted.
Honduras mahogany or wainscot moulded handrail. To be described if necessary with ramps, circular and twist, or with scroll and twist to the curtail step.
Spanish mahogany handrail is also similarly described.

If grooved for balusters, circular, or sunk for iron cores, mitred and turned caps, such to be mentioned.

Balusters and newels are described—

Deal square framed newels.
Deal square framed newels, chamfered.

Single and double turnings to newels to be mentioned, as also pendent drops, when used.

Deal square bar balusters.
Deal square bar balusters, dovetailed.

Carpenter and Joiner. (2285*f*.)

Turned balusters according to drawing, when necessary.

Planceer rounded on both edges, or moulded, as the case may be.

Fix all iron balusters and stays.

Sash frames are of great variety, whereof the following is a list: —

Deal cased frame for 1½-inch sashes, oak sunk sill with brass pulleys for single hanging.

Ditto, for double hanging.

Ditto, ditto, with circular head.

Ditto, circular on plan (and with circular head, when required).

Deal cased frames for 2-inch sashes, oak sunk sills with brass pulleys prepared for single hanging.

Ditto, prepared for double hanging.

If circular on head and plan, or either, such to be specified.

Deal-cased frames for 2-inch sashes, oak sunk sills with wainscot pulley pieces and beads, brass axle pulleys prepared to hang double.

If circular on head and plan, or either, such to be specified.

Deal cased frames for 2-inch sashes, oak sunk sills, mahogany pulley pieces and beads with brass axle pulleys, prepared to hang double.

The same description holds for 2½-inch sashes.

If, as before, circular on head and plan, or either, such to be mentioned.

Venetian frames are described as —

Deal cased frames for 1½-inch sashes, oak sunk sills, and prepared to hang single or double, as the case may be.

If circular on plan and head, or either, specify the same.

The above description for 1½-inch serves also for 2-inch and 2½-inch sashes.

If wainscot or mahogany, they must be so described.

Casement frames for French casements: —

Fir solid wrought frames for 1½-inch French casements, with oak sunk sills (plain or circular on the plan, as the case may be).

Fir solid wrought frames for 2-inch French casements and oak sunk sills (as before).

Fir solid wrought frames for 2-inch French casements and oak sunk sills (as before), with wainscot or mahogany styles and beads as may be correspondent with the sashes.

The same for 2½-inch sashes.

Fanlight frames over doors, which have nearly lost their employment from square lights having superseded them, are of —

1½-inch deal frames, square framed.

Ditto, semicircular head.

2-inch deal, square framed.

Ditto, semicircular head.

If elliptical, so describe them.

Sashes are to be described as follows: —

1½-inch deal ovolo (describe whether with circular head or circular on plan, if so).

2-inch deal ovolo (ditto).

2-inch deal astragal and hollow (ditto).

2½-inch deal astragal and hollow (ditto).

The above, if of wainscot, Honduras or Spanish mahogany, are to be so described, as also that they are to be hung single or double, as the case may be, with patent lines and iron weights, and patent sash-fastenings complete.

French casements are usually decribed as follows: —

2-inch deal ovolo casements. If with marginal lights or circular on plan, or both, describe them so; or if with astragal and hollow.

The same of 2½-inch, with the same modifications as in preceding article.

If either of the above be of wainscot, Honduras or Spanish mahogany, let them be so described.

It is usual to describe with these the hanging, which is commonly with 4-inch iron or brass butt hinges, and the species of fastening which it is common to place, at a sum varying from five to twenty shillings. When the turning Espaniolette fastenings are used, they must be particularly specified.

Shop-window sashes vary so much that we shall merely observe of their thicknesses, they are from 1½ to 2½ inches, and in the present extravagant rage for novelty among tradesmen, there is no end to the forms of their horizontal sections; — nothing, however *outré*, would be considered too extravagant for these people, and all that we can do is to say that, after describing their thickness, they are to be executed according to the drawings. In subjects of this kind too, the *stall*

CARPENTER AND JOINER. (2285*g*.)

board, and other fittings of the like nature, are to be specified in all, whereof the best way is to describe with reference to such drawings.

Friezes and cradling for cornices should always be referred to drawings, specifying generally their height.

Skylights, now usually made of metal; but if not, describe as follows: —

1½-inch deal ovolo skylight (if hipped, and with cross bars, state such).
2-inch deal ditto (ditto).
2½-inch ditto (ditto).

If astragal and hollow, or if of oak, such to be specified.

Kerbs for skylights are to be described —

1½-inch deal kerbs to circular skylights in two thicknesses, bevelled and chamfered.
2-inch ditto ditto.
2½-inch ditto ditto.

If elliptical, to be so specified.

Doors we shall, as in the preceding articles, describe, beginning with the commonest sort, for out-houses and the like.

¾-inch ledged wrought deal door.
Ditto, ploughed, tongued, and beaded.
1-inch wrought deal ledged ditto.
Ditto, ploughed, tongued, and beaded.
1¼-inch wrought deal ledged ditto.
Ditto, ploughed, tongued, and beaded.

1¼-inch and 2-inch deal ledged doors are similarly described.

These doors may be hung with HL or cross garnet hinges, or with cast or wrought butt hinges; and with bolts, locks, latches, and other fastenings, as the case may require. External doors with 4-inch butts, if that be the sort used, and internal ones with 3½-inch butts. Water-joint hinges are useful for light outside doors

Gates and coach-house doors are specified as —

2-inch deal, framed and braced, filled in with 2-inch deal, and ploughed, tongued, and beaded.
The same, filled in with battens.
2½-inch deal, framed and braced, filled in with 1-inch deal, ploughed, tongued, and beaded.
Ditto, filled in with battens.

If filled in with whole deal, it must be so specified.

2-inch deal bead butt and square gates, in eight panels.
2-inch deal bead butt and square gates, beadflush and square.
2-inch deal bead butt and square gates, bead flush on both sides.

If with more panels, or framed with a wicket, such must be specified.

The hanging of gates, and their hinges and fastenings, may be inserted according to the occasion of the work, at from 10*l*. to 15*l*. or even 20*l*., which may be declared in the specification as to the value at which they are to be provided.

1-inch deal 1-panel square doors.
1-inch deal 1-panel square doors, folding.

The above are rarely used: we shall now, therefore, proceed by the number of panels, up to 6-panel doors, beyond which they are to be so particularly specified, or with reference to drawings.

1¼-inch, 2 panels, square.
1¼-inch, 2 panels, bead butt and square.
1¼-inch, 2 panels, bead flush and square.
1¼-inch, 2 panels, moulded and square.
1¼-inch, 2 panels, bead butt on both sides.
1¼-inch, 2 panels, bead butt and bead flush.
1¼-inch, 2 panels, bead butt and moulded.
1¼-inch, 2 panels, bead flush on both sides.
1¼-inch, 2 panels, bead flush and moulded.
1¼-inch, 2 panels, moulded on both sides.

When hung folding, to be so specified.

1½-inch deal, 2 panels, square.
1½-inch deal, 2 panels, bead butt and square.
1½-inch deal, 2 panels, bead flush and square.
1½-inch deal, 2 panels, moulded and square.
1½-inch deal, 2 panels, bead butt on both sides.
1½-inch deal, 2 panels, bead butt and bead flush.
1½-inch deal, 2 panels, bead butt and moulded.
1½-inch deal, 2 panels, bead flush on both sides.

Carpenter and Joiner. (2285*h*.)

1½-inch deal, 2 panels, bead flush and moulded.
1½-inch deal, 2 panels, moulded on both sides.
2-inch deal, 2 panels, square.
2-inch deal, 2 panels, bead butt and square.
2-inch deal, 2 panels, bead flush and square.
2-inch deal, 2 panels, moulded and square.
2-inch deal, 2 panels, bead butt on both sides.
2-inch deal, 2 panels, bead butt and bead flush.
2-inch deal, 2 panels, bead butt and moulded.
2-inch deal, 2 panels, bead flush on both sides.
2-inch deal, 2 panels, bead flush and moulded.
2-inch deal, 2 panels, moulded on both sides.
2½-inch deal, 2 panels, square.
2½-inch deal, 2 panels, bead butt and square.
2½-inch deal, 2 panels, bead flush and square.
2½-inch deal, 2 panels, moulded and square.
2½-inch deal, 2 panels, bead butt on both sides.
2½-inch deal, 2 panels, bead butt and bead flush
2½-inch deal, 2 panels, bead butt and moulded.
2½-inch deal, 2 panels, bead flush on both sides.
2½-inch deal, 2 panels, bead flush and moulded.
2½-inch deal, 2 panels, moulded on both sides.

All these, as well as the following, must be specified as to be hung folding, if the nature of the work so requires.

1½-inch deal, 4 panels, square.
1½-inch deal, 4 panels, bead butt and square.
1½-inch deal, 4 panels, bead flush and square.
1½-inch deal, 4 panels, moulded and square.
1½-inch deal, 4 panels, bead butt on both sides.
1½-inch deal, 4 panels, bead butt and bead flush
1½-inch deal, 4 panels, bead butt and moulded.
1½-inch deal, 4 panels, bead flush on both sides.
1½-inch deal, 4 panels, bead flush and moulded.
1½-inch deal, 4 panels, moulded on both sides.
2-inch deal, 4 panels, square.
2-inch deal, 4 panels, bead butt and square.
2-inch deal, 4 panels, bead flush and square.
2-inch deal, 4 panels, moulded and square.
2-inch deal, 4 panels, bead butt on both sides.
2-inch deal, 4 panels, bead butt and bead flush.
2-inch deal, 4 panels, bead butt and moulded.
2-inch deal, 4 panels, bead flush on both sides.
2-inch deal, 4 panels, bead flush and moulded.
2-inch deal, 4 panels, moulded on both sides.
2½-inch deal, 4 panels, square.
2½-inch deal, 4 panels, bead butt and square.
2½-inch deal, 4 panels, bead flush and square.
2½-inch deal, 4 panels, moulded and square.
2½-inch deal, 4 panels, square, beat butt on both sides.
2½-inch deal, 4 panels, square, bead butt and bead flush.
2½-inch deal, 4 panels, square, bead butt and moulded.
2½-inch deal, 4 panels, square, bead flush on both sides.
2½-inch deal, 4 panels, square, bead flush and moulded.
2½-inch deal, 4 panels, square, moulded on both sides
1½-inch deal, 6 panels, square.
1½-inch deal, 6 panels, bead butt and square.
1½-inch deal, 6 panels, bead flush and square.
1½-inch deal, 6 panels, moulded and square.
1½-inch deal, 6 panels, bead butt on both sides.
1½-inch deal, 6 panels, bead butt and bead flush.
1½-inch deal, 6 panels, bead butt and moulded.
1½-inch deal, 6 panels, bead flush on both sides.
1½-inch deal, 6 panels, bead flush and moulded.
1½-inch deal, 6 panels, moulded on both sides.

If the panels of 1½-inch doors are raised, or if double marginal doors, so describe them.

CARPENTER AND JOINER. (2285*i*.)

Wainscot doors are usually as follow : —

1½-inch wainscot, 2 panels, square.
1½-inch wainscot, 2 panels, bead flush and square.
1½-inch wainscot, 2 panels, moulded and square.
1½-inch wainscot, 2 panels, bead flush on both sides.
1½-inch wainscot, 2 panels, bead flush and moulded.
2-inch wainscot, 2 panels, square.
2-inch-wainscot, 2 panels, bead flush and square.
2-inch wainscot, 2 panels, moulded and square.
2-inch wainscot, 2 panels, bead flush on both sides.
2-inch wainscot, 2 panels, bead flush and moulded.
2½-inch wainscot, 2 panels, square.
2½-inch wainscot, 2 panels, bead flush and square.
2½-inch wainscot, 2 panels, moulded and square.
2½-inch wainscot, 2 panels, bead flush on both sides.
2½-inch wainscot, 2 panels, bead flush and moulded.
1½-inch wainscot, 4 panels, square.
1½-inch wainscot, 4 panels, bead flush and square.
1½-inch wainscot, 4 panels, moulded and square.
1½-inch wainscot, 4 panels, bead flush both on sides.
1½-inch wainscot, 4 panels, bead flush and moulded.
1¾-inch wainscot, 4 panels, moulded on both sides.
2-inch wainscot, 4 panels, square.
2-inch wainscot, 4 panels, bead flush and square.
2-inch wainscot, 4 panels, moulded and square.
2-inch wainscot, 4 panels, bead flush on both sides.
2-inch wainscot, 4 panels, bead flush and moulded.
2-inch wainscot, 4 panels, moulded both on sides.
2½-inch wainscot, 4 panels, square.
2½-inch wainscot, 4 panels, bead flush and square.
2½-inch wainscot, 4 panels, moulded and square.
2½-inch wainscot, 4 panels, bead flush on both sides.
2½-inch wainscot, 4 panels, bead flush and moulded.
2½-inch wainscot, 4 panels, moulded on both sides.
2-inch wainscot, 6 panels, square.
2-inch wainscot, 6 panels, bead flush and square.
2-inch wainscot, 6 panels, moulded and square.
2-inch wainscot, 6 panels, bead flush on both sides.
2-inch wainscot, 6 panels, bead flush and moulded
2-inch wainscot, 6 panels, moulded on both sides.
2½-inch wainscot, 6 panels, square.
2½-inch wainscot, 6 panels, bead flush and square.
2½-inch wainscot, 6 panels, moulded and square.
2½-inch wainscot, 6 panels, bead flush on both sides.
2½-inch wainscot, 6 panels, bead flush and moulded.
2½-inch wainscot, 6 panels, moulded on both sides.
2-inch wainscot *sash-doors*, with diminished stiles, lower panel moulded, bead flush, with astragal and hollow sash.
2-inch wainscot sash-doors, with diminished stiles, lower panel moulded, bead flush, with astragal and hollow sash, moulded on both sides.
2½-inch wainscot sash-doors, diminished stiles, lower panels moulded, and bead flush, with astragal and hollow sash.
2½-inch wainscot sash-doors, diminished stiles, lower panels moulded, and bead flush, with astragal and hollow sash, moulded on both sides.

If any of these are to be hung folding, double margined, or moulded on the raising, such must be specified.

Mahogany doors as follows : —

2-inch Honduras mahogany doors, 2 panels, moulded and square.
2-inch Honduras mahogany doors, 2 panels, moulded on both sides.
2-inch Honduras mahogany doors, 4 panels, moulded and square.
2-inch Honduras mahogany doors, 4 panels, moulded on both sides.
2-inch Honduras mahogany doors, 6 panels, moulded and square.
2-inch Honduras mahogany doors, 6 panels, moulded on both sides.
2½-inch Honduras mahogany doors, 4 panels, moulded and square.
2½-inch Honduras mahogany doors, 4 panels, moulded on both sides.
2½-inch Honduras mahogany doors, 6 panels, moulded and square.

Carpenter and Joiner. (2285*k*.)

2½-inch Honduras mahogany doors, 6 panels, moulded on both sides.

If any of these are hung folding, with projecting mouldings, or with double margins, it must be so specified. The last set of doors, if required to be of a better description, may be specified of the best Spanish mahogany.

2-inch Honduras mahogany sash-door, astragal and hollow, bottom panel moulded and square.

2-inch Honduras mahogany sash-door, astragal and hollow, bottom panel moulded on both sides.

2½-inch Honduras mahogany sash-door, astragal and hollow, bottom panel moulded and square.

2½-inch Honduras mahogany sash-door, astragal and hollow, bottom panel moulded on both sides.

If hung folding, or with double margin, or diminished stiles, to be so specified.

External doors are of varieties, as follow: —

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels square both sides.

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels bead butt on the back.

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels bead flush on the back.

If the panels have raised mouldings, specify them.

2½-inch deal, 4 panels, the lower panels bead butt and square, upper panels square on both sides.

2½-inch deal, 4 panels square, bead butt on the back.

2½-inch deal, 4 panels square, bead flush on the back.

Specify raised mouldings, if any.

2-inch deal, 6 panels, lower panels bead butt and square, upper panels square both sides.

2-inch deal, 6 panels, lower panels bead butt and square, upper panels square, bead butt on the back.

Specify raised mouldings, if any.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square both sides.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square, bead butt on the back.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square, bead flush on the back.

If with raised mouldings, so describe them; also, if double margined, &c.

Any of these external doors, if hung folding, or with circular or curved heads, must be so specified.

Sash doors are of the following varieties: —

1½-inch deal, 2 panels, square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, bead butt and square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, bead flush and square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded and square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded and bead butt, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded and bead flush, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded on both sides, diminished stiles, and ovolo sash.

2-inch deal, 2 panels square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, bead butt and square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, bead flush and square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded and square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded and bead butt, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded and bead flush, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded on both sides, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, square, with diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, bead butt and square, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, bead flush and square, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded and square, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded and bead butt, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded and bead flush, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded on both sides, diminished stiles, and ovolo sash.

If hung folding, or with marginal lights, to be so described.

It is the practice in describing joiner's work, to specify the ironmongery used with it, that is, the hinges, locks, fastenings, and furniture; and we have accordingly mentioned the hanging and fastening of common doors, and gates, and coach-house doors

CARPENTER AND JOINER. (2285*l.*)

Common framed 4-panel doors are usually hung with 3½-inch butts and 7-inch iron rim stock locks. Better doors are hung with 4-inch iron or brass butts, mortice locks and brass nob furniture. Folding doors, if heavy, should have 4½ or 5-inch brass butts, and if necessary to clear mouldings, they should be hung with projecting brass butts, and should moreover be provided with flush and other bolts, and mortice locks and furniture. Doors of dining, drawing, and other rooms, where they are required to clear the carpet by rising as they open, should have 4 or 4½-inch rising joint butts. For closet doors, 3½-inch butts are usually described with brass tumbler locks and keys. External doors require the provision of larger locks, which are usually iron rim locks with 10 or 12-inch bright rod bolts, chains, staples, &c. Shutters when hung are with butts, which for the back flaps are of a less size, and spring bar fastenings should be specified to them. Brass nobs to the front flaps.

Moulded architraves to doors and windows are described by their width.

Columns and pilasters are usually described—

1½-inch deal diminished columns, . . . inches diameter.

1½-inch deal diminished columns, . . . inches diameter.

Pilasters similarly specified. Both one and the other to be glued up and blocked.

If fluted, to be mentioned; as also necking grooves to columns. Caps and bases according to the order, carved or of papier maché, as the expense will allow.

Entablatures got out of deal, as per drawing, provide glued, blocked, and fixed with all necessary brackets and grounds.

Water-closets are fitted up with 1-inch clean deal (wainscot or mahogany), seats, risers, and clamped flaps, square skirtings, all requisite bearers and pipe-casing; and the joiner is to attend on the plumber while fixing the basins and other work. *Privies* are described as to seats and risers the same as water-closets.

Cisterns, internal and external, must have their cistern cases proportioned in thickness to their sizes; thus one about 3 or 3 feet 6 inches long, and 2 feet 9 inches deep, will do on 1¼-inch deal dovetailed: it should be described with requisite bearers, and a cover of ¾-inch deal with a wood handle. For a good-sized external cistern, we should specify, provide and fix a wrought and dovetailed 2-inch deal cistern case, . . . feet long, . . . feet wide, and . . . feet deep in the clear. Find and fix all necessary bearers for the same, together with all other requisite fittings, and further provide a ¾-inch deal strongly ledged cover, with saddle-back fillets and water-channels at each joint, as shall be directed.

Cisterns for water-closets.

Each to have cistern cases of 2-inch deal capable of containing 36 cubic feet of water, fixed with strong bearers and ledged covers of ¾-inch yellow deal tongued and beaded.

Sinks, describe as under, when wooden ones lined with lead are used.

1½-inch dovetailed sink, enclosed with 1½-inch deal square-framed front, and door hung with 3-inch butts and other necessary ironmongery.

Warm bath.

To be fitted up (of the best Spanish mahogany) with riser, frame, and clamped flap, provided and fixed with all requisite bearers and other fittings and appurtenances. The flap to be moulded in front, and hung with 3½-inch butt hinges, and the riser panelled and moulded as shown in the drawings.

Dressers. The following is a specification for a good house.

Provide and fix a dresser in the kitchen, of 2-inch deal, with cross-tongued top 10 feet long and 2 feet 9 inches wide, supported on strong framed legs and bearers. 1-inch deal pot-board and bearers. Six 1½-inch sunk shelves, whose widths are to average 7 inches. Back of the shelves to be of 1-inch deal, wrought, beaded, grooved, and cross-tongued. 1-inch deal top, 14 inches wide, with moulded cornice. Five drawers with bottoms and dovetailed rims of ¾-inch deal. The fronts to be of 1-inch deal, beaded. A brass drop handle and a good patent tumbler lock to each drawer, together with all slides, runners, bearers, and other requisite appurtenances.

Dresser top for scullery, 1½-inch clean deal, 2 feet 6 inches wide and 6 feet long, cross-tongued and fixed upon strong wrought and framed legs and bearers.

Plate-rack for scullery to be provided over the sink, and of the same length. Sink as above described.

Spit-rack to be provided over the kitchen chimney, or other convenient place, as may be directed.

Dwarf closets, if any are used, may be of 1-inch deal, square framed and moulded in front, the doors to be hung with 2½-inch butts, and to have tumbler locks.

Pipe casings, wrought and framed, to be provided where necessary, to hide lead pipes of all descriptions, and fronts to unscrew for coming at the pipes in case of defects therein.

Carpenter and Joiner. (2285*m.*)

Fittings for larder, as follow: —

Provide a clean deal dresser top, 1½ inch thick, 2 feet 6 inches wide, and . . . feet long, to be feather-tongued and fixed on strong framed legs and rails. Two meat rails, 6 feet long, of wrought fir, 3½ by 2 inches, suspended from wrought iron stirrups. Provide also a hanging shelf, 6 feet long, 10 inches wide, and 1¼ inch thick, to be similarly suspended by wrought iron stirrups.

Laundry to be fitted up with 1½-inch clean white deal washing troughs, wrought two sides, and splayed and put together with white lead, as shown on drawing. 1¼-inch deal ironing board, wrought both sides and clamped, properly hung with hinges to a hanging stile. Provide two clothes racks, hung with pullies and ropes to the ceiling to raise and lower the same.

Dust bin, where shown on the plan, to contain 30 feet cube, the whole to be of oak, with proper slides, in front; or with brick walls and deal top, and cover with water joint hinges.

Arris gutters to eaves should never be of wood: zinc or copper are better materials, and we do not therefore think it necessary to describe them.

Fittings to shops are so various that they must be referred to drawings; and with their own distinct specification. So of *shop fronts.*

Stable fittings are specified as follow—where the old class of work is required:—

Mangers, &c. 2-inch deal bottoms and 1½-inch deal sides. Wrought oak manger-rails, 4 by 3 inches. Wrought, rebated, and rounded oak manger post, 6 by 4 inches, wrought and framed with bearers thereto. Oak heel-posts, wrought, 6 by 5 inches, and groove for partitions. Oak top rails, 5 by 4 inches, grooved and rounded at the top. Oak bottom rails, wrought, 4 by 4 inches, grooved and arris rounded off. 1½-inch deal partitions, wrought on both sides, ploughed, tongued, and beaded. 1¼-inch deal rails on each side, board wide, and the arrisses rounded off. Stable fittings have now become an almost distinct trade.

Fronts to hay-racks. Oak standard, 4 by 4 inches, wrought and framed into oak bearer under the manger. 1¼ inch deal fronts framed for the reception of cast-iron hay-racks well secured. Fix fir bearers and 1-inch deal partitions at each end of hay-racks, with fir arris rails 3 inches apart at the bottom of each rack.

Dressings over stalls connected with heel-posts. 1-inch deal frieze, wrought joints, feather-tongued, and backings thereto, segmental sofites and keystone in centre of arches. Impost moulding at the springings and moulded cornice to girt about 10 inches.

Line the walls to the height of 5 feet with 1-inch yellow deal, wrought, ploughed, tongued, and beaded, with a ⅝-inch beaded capping thereon.

Churches. To give general directions for the specification of a church would be impossible. The principles of its timbering may be collected from what has preceded. *Pewing* is executed as planned on the drawings, of whole deal (generally) square-framed partitions two panels high; 1½-inch framed doors and enclosures one or two panels high, with stiles, munnions, and top rails 3 inches wide, and bottom rails 6 inches wide. The panels of the doors and enclosures should not be more than a board in width, and the framework round them chamfered. The doors are hung with 3-inch butt hinges, and should have brass nob pulpit latches. Capping to the whole of the pewing, grooved and moulded according to drawing. *Pew fittings* are, 1½-inch wrought and rounded seats 12 inches wide, with proper bearers and 1¼-inch cut brackets not more than 3 feet apart. Seats rounded next the pew doors. *Flap-seats* in the galleries to have strong joints. All the pews to have ¾-inch book boards 6 inches wide, with ½-inch rounded capping bearers, and ½-inch cut brackets thereunder, not more than 2 feet 6 inches apart, and the ends rounded next the pew doors. If there be an organ, its enclosure and the free seats adjoining it should correspond with the pew enclosures. *Free seats* of 1¼-inch deal, as shown in the drawings. The seats to be 11 inches wide, rounded in front. Backs framed with stiles, munnions, and rails, 3½ inches wide, and the standards, ends, and bearers, according to the drawings. *Children's seats* to be of 1¼-inch deal, with brackets same thickness, not more than 2 feet 6 inches apart; at least 8 inches wide, and the flap seats, where they occur, to be hung with strong butts. *Pulpits and reading desks* are usually of 1¼-inch deal, framed according to drawings, with 1¼-inch doors, hung with brass hinges and pulpit latches. Whole deal floors on bearers, 1-inch book boards, cappings and bearers. 1-inch clean deal or wainscot steps and risers, moulded returned nosings, 1¼ inch, beaded, sunk and cut string boards, strong bracketed carriages. 1-inch square framed sofite under pulpit floor and stairs, mahogany or wainscot moulded handrail, with caps turned and mitred; square bar balusters with one in ten of iron; turned newels to block steps; seats of 1¼-inch deal, 13 inches wide, and proper bearers thereto, together with all appurtenances and requisite fittings for executing the drawings.

CARPENTER AND JOINER. (2285*n*.)

The carpenter and joiner is to provide all such jobbing work, in following or preceding the other artificers engaged on the works and their appurtenances, as may be requisite for the completion thereof in every respect, without any extra charge.

2286. FOUNDER, SMITH, AND IRONMONGER. For describing cast iron girders and columns, reference must be had to Chap. I. Sect. X. (1628*e*, *et. seq.*), wherein will be found the method of determining their scantlings—for which no rule can be given that is not dependent on the results there laid down. Having determined the weight to be borne, no girder (and such should be inserted in the specification) should be allowed to be used, that has not been previously tested by *weighting* it at the foundery.

Cast iron cradles are sometimes used for openings, which must be described for the particular occasions as they occur.

Chimney bars are described usually as follows: —

Provide and fix to kitchen chimney two wrought iron cradle bars, each 2 inches wide and ¾-inch thick, long enough to extend to the outside of the chimney jambs, and turned up and down at each end. The other chimneys are to have wrought iron chimney bars 3 inches wide and ½ inch thick.

Straps, stirrup irons, nuts, bolts, screws, and washers, together with all other wrought iron work for the roofs and partitions, to be provided, as may be requisite for tying in and securing all carpentry, and the smith is to deliver to and assist the carpenter in fixing or attaching the same.

Where the quantity is uncertain, a given weight beyond the above general direction should be provided in the contract, such part thereof as may not be wanted to be deducted from the accounts after the rate of . . . per cwt.

Provide all necessary cramps of cast and wrought iron, as may be directed, for the mason, the former to be used where the works are exposed to the air.

Wrought iron doors to be provided for strong room (or if opening in a party wall), folding, and of the best quality, as shown in drawing; with hinges and proper fastenings, of the value at least of 25*l*.

If *cast iron sashes* are used in any part of a building, they are to be provided with reference to drawings.

Wedges for underpinning must be described with reference to the thickness of walls they are to catch: each pair must be at least as long as the wall is thick.

Balusters to a back stone staircase and landings are described —

Wrought iron balusters, ¾ inch square, with turned wrought iron newel equal to 1½ inch diameter, with rounded handrail of wrought iron 1½ by ½ inch. The balusters and newel are to be riveted into the handrail at top, and at the bottom let into the stone work and run with lead.

Balusters to a principal staircase are described —

Ornamental cast iron balusters, as shown on the drawings, with top rail of wrought iron 1¼ by ½ an inch, let into and firmly screwed to the mahogany (or wainscot) handrail. The balusters and newels are to be riveted into the iron rail, and at the bottom they are to be let into the stonework and run with lead

Balusters of wrought iron to be provided for strengthening the principal staircase when not of stone. Every tenth baluster to be of wrought iron, properly fastened.

Provide and fix . . . knockers for . . . doors to . . . .

Air bricks of cast iron to be provided and fixed in the brickwork for the ventilation of the floors.

Air gratings, . . . in number, to be provided, 9 inches square, and fixed round the lower part of the walls of the house.

Area gratings, . . . to each area (if any there be), to be prepared and fixed of cast iron, with bars 1½ inch by ¾ of an inch, and not more than 1½ inch apart. Frames 1½ inch by 1 inch, and with strong flanges to let into the surrounding stone-work.

Window guards of wrought iron to the windows of . . . , and . . . bars to be 1 inch square and 4 inches apart, with framework of iron of the same substance securely fixed to the brickwork.

Cast iron rain-water pipe, for a large size stack, is described —

6 inches diameter, to lead from the roof down into the drain, with head and shoe complete.

Coal plates (if more than one) of cast iron, with proper fastenings to be fixed over the coal shoot.

Cast iron ornamental railing, as per drawing, to the windows, or to the stone balcony in front of the house, as the case may be.

Air traps of cast iron to all communications of surface water with drains to be of appropriate size, and provide all gully-hole gratings that may be necessary.

To provide for the carpenter's and joiner's works, and use and fix thereto, besides that

Founder, Smith, and Ironmonger. (2286*a*.)

which has been already described, all requisite spikes, nails, screws, and other proper ironmongery, and all requisite brass work, both to be of the very best quality.

Provide a copper, . . . inches diameter, and stewing stoves as shown on the drawings, with all requisite bars and iron work.

For fittings to stables describe —

No. . . . Cast-iron hay-racks, 3 feet wide and 2 feet high in the clear. $1\frac{1}{4}$-inch round staves, about 3 inches apart, the frames $1\frac{1}{4}$ by $\frac{3}{4}$ of an inch, with the arris rounded off next the staves. Provide and fix two manger rings in each stall.

Cast iron coping to the walls of the dung-pit of the thickness of $\frac{7}{8}$ of an inch, and returned on each side 4 inches down at the least.

Cast iron gratings to stable yards are usually described as of the weight of 1 cwt.

For church and chapel work, the founder's, smith's, and ironmonger's work is so dependent on the design, that no general instructions for specifications can be given. The following are the only peculiarities: —

Provide *cast iron saddle bars* for the windows $\frac{5}{8}$ by $1\frac{1}{4}$ inch, 12 inches longer than the clear width of each window, laid into and worked up with the brickwork, at the height shown on the drawings.

Provide to each window wrought iron framework for a hopper casement, as shown on the drawings, and fit up the same complete, with patent lines, brass pulleys, and all other requisite appurtenances.

2287. Plasterer. To *lath, plaster, float,* and *set* all the ceilings and strings of staircases, and the quartered partitions of the . . . chambers (such as servants' rooms) on attic stories.

To *render, float,* and *set* all brickwork in attic stories.

To plaster all sides of the kitchen offices and office passages with best floated rough stucco, lathed where requisite.

All the remainder of the sides of the interior throughout is to be executed with the very best floated stucco, lathed where requisite. Stucco of offices (or office buildings if any) to be finished with rough surfaces; all the rest of the stucco to be troweled quite smooth.

All the arched, groined, panelled, and coffered work, and the bands and architraves, to be executed in guaged stuff, in the best and most accurate manner.

To run plaster cornices round the several rooms, lobbies, passages, and other parts of the building, with enrichments thereto accurately modelled according to the drawings (the enrichments, if so wished, to be described as of papier maché). A centre flower to each room on the ground and one-pair floor, where marked, securely fixed to the ceiling. These are, on all accounts, better for security in the papier maché, as they can be then screwed to the ceiling.

Basement or ground story (or both, as the case may be) is to be run round in all the rooms, lobbies, passages, &c. with *skirtings of Parker's cement,* 10 inches high, $1\frac{1}{4}$ inch thick, whited when soft, and finally washed of stone colour.

The plasterer is to execute all necessary beads, quirks, and arrisses. To stucco all internal and external reveals, to dub out where the work may require it, so as to bring out all extra thicknesses and projections, and to counter-lath the work over large timbers and elsewhere, as may be necessary.

The lathing throughout is to be performed with lath-and-half heart of fir laths, free from sap. Enrichments to be carefully trimmed and finished off, and where heavy leaves or embossed work may require it, to be screwed with strong copper screws.

The ceilings on the two principal floors are to be distempered by the painter. All the rest of the ceilings, strings, and mouldings are to be whitened.

The sides of the rooms in the attic or garret (as the case may be) stories, as well as the lobbies, closets, passages, &c., are to be finished of such stone colour tints as the architect may direct.

Lime-white stables and coach-house walls, larders, sculleries, cellars, including vaulting under sides of floors where open, &c.

When Parker's cement is used for external works, describe as under: —

To stucco in the very best manner with Parker's cement, jointed to imitate masonry, the whole (or part, if such be the case) of the exterior of the building, with columns, pilasters, plinths, entablatures, strings, mouldings, labels, jambs, reveals, chimneys, chimney moulds, decorations, enrichments, and appurtenances of every kind, as shown on the drawings and profiles. Such works to be subject to such further instructions from the architect as he may think proper, and to be roughly coloured as each portion is executed, and finally coloured when the architect shall so direct, with weather-proof colour-

PLASTERER. (2287*a*.)

ing, fixed with Russia tallow, beer grounds, tar, and the other proper ingredients.

Where desired, decorative chimney pots, of Parker's or other cement, and of the value of two guineas, to be provided for each flue.

Pugging. To fill in upon the sounding boarding between the joists, where so provided, with good lime and hair pugging mortar, laid throughout 1 inch in thickness.

Roughcasting. For the mode of describing this, see Plastering, Sect. IX. (2249.)

2288. PLUMBER. To lay the *flats and gutters* with milled lead of 8 lbs. to the foot superficial. Where against walls, to be turned up 7 inches; where against slopes, as rafters, to turn up 10 inches. Rolls not to exceed 27 inches apart.

Work *flashings* of milled lead in the walls of 5 lbs. to the foot, and to turn down over gutters and flats. Where flashings adjoin the slopes of a roof, they should be described to be laid stepwise into the brickwork, and of an average width of 12 inches.

Hips and ridges to be covered with milled lead 6 lbs. to the foot, and at least 18 inches wide, well secured with lead-headed nails.

Where eaves gutters are used, describe as follows: —

To put round the eaves at the curb plate 4-inch copper (or zinc) guttering, fixed complete with bands and brackets, with copper (or zinc) pipes . . . . inches diameter, with neat heads and appropriate shoes to lead into the gutter or drain.

Domes should be covered with lead from 6 to 8 lbs. to the foot superficial, according to their size, and must be well secured with proper seams or rolls thereto.

For coverings of *zinc* the reader is referred to Sect. VIII. Chap. II. (1792, *et seq.*) and Sect. VII. Chap. III. (2224*g*.) of this Book.

Tops and sides of dormers to be covered with 5-lb. milled lead, turned down all round full 8 inches. A flashing of 5-lb. milled lead 30 inches wide, to be fixed over the sill of the dormer door or window, as the case may be.

Aprons of 6-lb. milled lead, and 10 inches wide, should be described to sky-lights.

External mouldings of wood should be covered with 6-lb. milled lead, to turn up 6 inches, and to have flashings of 4-lb. milled lead let into the brickwork, and to be turned down 5 inches.

To fix . . . . *stacks of rain-water pipes* from the gutters to the drains, of (5) inches bore, turned up from milled lead of 8 lbs. to the foot superficial, and securely fixed with ornamental cistern heads as shall be approved by the architect, and 2-inch strong overflow discharging pipes. Similar description for conveying water from a portico. A lead rose is often placed over water pipes to prevent stoppage.

No pipes but of lead or zinc should be used against stone buildings. Cast iron pipes should only be used to offices.

In London, it is usual to specify that the water should be laid on for the service of the house in following manner (Regulating cisterns are required by some Companies):—

To lay on from the main of the . . . . . Company water with $\frac{3}{4}$-inch strong cast lead pipe to the cistern of the upper water-closet, with ball-cock complete. Similarly to lower water-closet and to such other cisterns as are provided, with ball-cocks, &c. complete, and to pay all official fees.

Line the sinks in the scullery and butler's pantry (and other small ones, if any) with 6-lb. milled lead, and fix thereto 2-inch waste pipes, with brass bell traps complete to go into the drains.

Line the kitchen cistern with milled sheet lead, bottom 9 lbs. and sides 6 lbs. to the foot, with all soldering thereto. To provide to the same a $1\frac{1}{4}$-inch waste pipe. Line the kitchen sink with lead of 8 lbs. to the foot, to turn well over the woodwork and to have a 2-inch strong waste pipe to lead into the drain, with brass bell grate complete. A $\frac{3}{4}$-inch service pipe and brass cock to be provided from the cistern for supplying water to the sink.

Roses pierced with holes of sufficient dimensions to be provided of 10-lb. lead to gutters and rain-water cesspools.

Water closets to be constructed and fitted up in every respect complete, with blue basin, and the very best patent valve apparatus. Soil pipe of $4\frac{1}{2}$-inch bore out of 8-lb. lead, to lead into drain with strong D trap, lead service box, 10 inches by 7, and 6 inches deep, of 10-lb. milled lead; 5-lb. lead safe under pan, with 2-inch swan-necked waste pipe. 1-inch supply pipe to the basin, and all other pipes, wires, cranks, handles, and other proper fitments. The *cistern* is to be lined, bottom with 8-lb. cast lead, and sides with 5-lb. milled lead. $1\frac{1}{4}$-inch waste pipe, soldered in below the dip, with washer and waste complete. (See 2218.)

Inferior water closets to be provided with strong cast iron trapped pan (or stoneware syphon pan) with water laid on, and in all respects to be fitted complete.

Provide all stench-traps that may be requisite where the pipes communicate with the drains.

PLUMBER. (2288*a*.)

For a cold bath provide and fix a . . . feet . . . inches bath of copper of 16 ounces to the foot superficial, tinned on the inside, and painted in japan to imitate marble, or as may be directed. Lay on the water with strong $1\frac{1}{4}$-inch lead pipe, with brass cock, and fix $2\frac{1}{2}$-inch strong lead waste pipe, with brass washer and plug, thereto.

If the hot bath be not of marble, the following clauses will describe the several positions and varieties of the boilers by which a supply of hot water is obtained in the present day:—

I. Provide a Tylor and Sons' 5-feet 2-inch taper oval-end copper (or galvanized tinned iron) bath, white marbled inside, with copper pipes, mounted in wood cradle, with $1\frac{1}{2}$ inch deal framing panelled with French polished Honduras mahogany top. Three of Tylor and Sons' inch roundway bath taps, S.B., with socket keys and handsome levers, hot, cold, waste. A Tylor and Sons' patent bath boiler, with stove front to fit opening of fireplace, with doors and damper (no setting required). Inch lead pipe from cold water cistern to boiler, $\frac{3}{4}$-inch lead pipe to relieve boiler up to and turned over top of cistern (or any convenient outlet). Inch lead pipe for hot, cold, waste, and overflow pipes to bath. Lead safe with waste under cocks, and leave the work perfect; as estimated, at 39*l.* 0*s.* 9*d.*, exclusive of carriage and any bricklayer's, plasterer's, or carpenter's work, cutting away for pipes and making good, fixing bath framing, and graining and varnishing it. A galvanized tinned iron bath is 6*l.* less.

II. Tylor and Sons' 22-gallon copper chimney boiler, with wrought iron band, with bolts and nuts to carry ditto, and stove front to fill up opening in fireplace, with sliding blower, revolving damper, soot door, and bars; as estimated at 38*l.* 0*s.* 9*d.*

III. Tylor and Sons' copper saddle boiler with unions, a stove front to suit ditto, with sliding blower, revolving damper, soot door and bars. A galvanized wrought iron cistern, close top, with manhole screwed down, to be fixed with two lines of inch wrought iron pipe from boiler to hot cistern, inch ditto to supply cold water to hot cistern, $\frac{3}{4}$-inch ditto to relieve hot cistern, inch hot, cold, waste, and overflow pipes to bath, &c.; as estimated at 47*l.* 4*s.* 3*d.*

IV. Provide a 5-feet (larger or smaller, as deemed necessary) strong best make improved kitchen range, with strong wrought iron back boiler with close top, wrought iron oven, and line fireplace with panelled covings. A galvanized wrought iron hot water cistern, &c.; as estimated at 61*l.* 3*s.* 9*d.*

V. The range fitted with two boilers, one for the bath, the other for domestic use; where a fire is kept sufficiently large to work two boilers, they are recommended. Estimate 4*l.* extra to No. IV.

VI. A range with partially closed fire instead of one with open fire. 4*l.* 15*s.* extra to No. IV.

VII. Tylor and Sons' 22-gallon copper dome-top boiler, with furnace iron work, doors, bars, and damper, and continue as No. I. This boiler may be fixed in the basement, and will supply a hot bath in any apartment below the level of the cold water cistern. As estimated, 43*l.* 15*s.* 3*d.*

NOTE. In I., the bath and boiler may be fixed in the same or separate apartments; open or close fire at pleasure. All the estimates are framed presuming on a cold water cistern and a rain water pipe, or a drain, being within 10 feet of the room. In III., the hot water cistern is placed over the fireplace in the room. In IV., the hot cistern is supposed to be 25 feet above the boiler. In VII., the cold cistern is supposed to be 25 feet above boiler. The waste pipe from the bath to the drain should always have as great a fall as possible, and never be laid to so small a fall as allowed by placing it within the depth of the floor.

Common pumps are generally described as 3-inch pumps, with neat cast iron cases fixed complete, with proper lead suction pipe to bring sufficient supply of water from well, and all other appurtenances. The manufacturer's stock to be seen if others be required.

To provide and fix (this where the water is not laid on, as in London), a $3\frac{1}{2}$-inch lifting engine pump, with brass barrel; and provide from the well . . . feet of $1\frac{1}{2}$-inch strong suction pipe. Service pipes to the cisterns, with all cocks and joints that may be necessary.

Provide all wrought copper and zinc nails that may be wanted for laying the metal works.

To provide in the contract . . . . cwt. extra of cast sheet lead, including labour and all proper materials as may be wanted and directed by the architect; and if the same or any part thereof should not be used, there shall be a deduction made for the same on making up the accounts, after the rate of . . . . per cwt. for such portion thereof as shall not have been used. Also extra of milled lead.

2289. GLAZIER. To glaze all the windows with best crown glass; the offices with second crown glass. To glaze all the front windows with best sheet glass; or with best flattened sheet; or with patent plate; or with British plate; as the case may be, and according to the weight to be specified. For varieties of glass and glass for other purposes, see Chap. II. Sect. XII. *par.* 1870, *et seq.* The architect very often names the manufactory from which the glass is to be procured, to ensure the proper quality being supplied.

All the glazing is to be properly bedded, stopped in, sprigged, and back-puttied, the convex side outwards (of crown and sheet glass), to be free from specks, blisters, or other blemish; and to be left whole and clean, on the works being rendered up as complete.

The whole of the windows, including the hopper ventilators and the diamond shaped ventilator (of the church, robing room, &c.), are to be glazed with .... glass, in strong lead quarries, firmly soldered at the angles, and tied to the saddle bars. The lights to be fixed into the grooves and stopped in with white lead.

2290. PAINTER. To knot (with silver leaf in best work), to pumice down and smooth, to stop, and otherwise to properly prepare all the wood and other works intended for painting.

To paint four times in oil, or till they bear out, with the best oil and colour, all the internal and external wood and iron works, all the stucco, and all other works that are usually painted.

The walls of the principal staircase, lobbies, and entrance hall are to be imitations of marbles, jointed like masonry, in blocks of sizes as shall be directed, and twice varnished with the best copal.

The doors, shutters, dadoes, skirtings, boxings, architraves, and other dressings on the ground and one-pair floors (and others if required), are to be grained wainscot (or other wood as may be specified), in an artist-like manner, and sized, and varnished twice with best copal varnish.

If any of the mouldings of doors and shutters are to be gilt, specify the same.

Distemper the ceilings (or as follows):—

The ceilings and cornices on ground and one-pair floor to be painted four times in oil, and flatted and picked in with such extra colours as may be directed.

To flat extra, of such tints as may be directed, all the rest of the stucco work and wood work on the principal and one-pair floors.

Sashes to be finished on the outside of .... colour. The plain painting to be of tints of brown, drab, or stone colour, as may be directed.

To French polish in the best manner the handrail of the staircase, the mahogany work of the bath and water closet, and other parts (if any).

2291. PAPERHANGER. To prepare and bring to a proper face all the walls and surfaces intended for papering.

To hang with figured paper, value .... per yard, the rooms (to be described) on the .... floor, with borders (as may be desired).

The remainder of the rooms to be hung with paper .... per yard, with or without borders.

Where satin paper is to be put up, or any of the more expensive descriptions, then to underline, or line the walls, with lining paper, and hang with .... paper of .... shillings per piece, the rooms on the .... floor. Borders also, if thought desirable, must be specified.

To paper the entrance passage or hall, staircase, and landings, up to .... with Siena marble (or other) paper, value .... per yard, hung in blocks, or hung horizontally and lined to sized blocks with brown lines (or black pencil), twice sized, and varnished (once or twice) with best copal.

Provide and fix with needle points a ¾-inch gilt .... moulding round the dressings, and along the top and bottom of the .... room, or .... rooms.

All the patterns are to be approved by the architect or his client.

2292. BELLHANGER. To provide and fix with all necessary wires (concealed or otherwise), pulls, cranks, and every other appendage, bells from the following places:—[Here enumerate the places.].

It is usual to mark the place both up and down stairs where the bells are to be hung; and where there are many of them together they are sometimes described to be so tuned as to form a musical scale.

The electric, or the pneumatic, bell system will depend upon the patent selected.

SPECIFICATION ADDENDUM FOR RECENT IMPROVEMENTS.

2293. Excavator. Cover over the spaces under paved or tiled floors (except where the tiles are laid on joists) with broken bricks well rammed and grouted with liquid mortar. This layer is to be made of sufficient thickness to receive 6 inches of concrete, which is to be properly rammed and covered with a layer of 2 inches of fine concrete, finished with a level surface.

2293*a*. Bricklayer. Foundations to piers of arches to be in brickwork of hard bricks, laid in cement, and every course throughout the foundations to be well grouted.

When the building is to be heated with hot air or hot water, then;—build furnace room where shown on plan, with flues as necessary: or, build channels for hot water pipes under floors; the channels to be 2 feet high by 12 inches wide in the clear, resting upon 3 inches of concrete and a double course of Bangor duchess slates to form channel floors; the sides to be half a brick thick in mortar.

Build 9-inch sleeper walls to support ends of joists of wood floors abutting upon paved floors (as in a church), and build half-brick honeycomb sleeper walls on one brick footings, 4 feet apart, under all wood floors in basement, or on ground floor when not excavated under.

Lay in drains of glazed socketed stoneware pipes of Lambeth (or other) manufacture, as shown on drawings, of the clear internal diameters there figured, and at the depths below the surface as figured. Provide all necessary bends and junctions. All the pipes to be jointed in cement, and the drains to be properly connected with the sewer (or cesspool). The outlet of the drain to have a galvanized iron flap to shut flush all round.

Insert a damp-proof course of Bangor slates in cement in all walls throughout their entire thickness 3 inches lower than the general level of the ground floor (and where else as needed). See Chap. III. Sect. I. *par.* 1886*b*, *et seq.*, for other methods of obviating the rise of damp.

The moulded bricks to be carefully made in accordance with the detail drawings, and to be trimmed up before they are placed in the kiln. They are to be made a little thicker than the other bricks, so that the beds and joints may be rubbed true before they are laid; they are to be set in fine mortar, and (before the scaffolding is struck), they are to be rasped, rubbed with gritstone, and the arrises to be made as straight and true as stonework.

Work into the exterior and interior faces of the walls (if required), crosses, diapers, zigzags, or other patterns; and form bands, string-courses, &c., with white, black, red, or other bricks, as shown on the elevations, &c. The red and black bricks are to be laid in blue-black mortar, or the joints to be raked out and pointed with the same.

Brick relieving arches that are visible, are to be formed of three or four courses of red and black bricks, alternately or otherwise, as shown, or as the architect may hereafter direct.

A specimen brick of every description, splayed, moulded, for facing, &c. to be submitted to the architect for his approval before the commencement of the work.

Hollow walls for exposed situations. The external walls above the plinth line are to be built with a hollow cavity in the middle of about 3 inches, having courses of bonders or through stones not more than 1 foot apart in height, and of various widths, but never more than 2 feet 6 inches apart. At the level of the top of the plinth, a course of thick slates, or of thin stones, is to be worked on the walls, closely bedded in strong mortar under all the voids or flues thus formed, and a small aperture, 9 inches by 6 inches, is to be made for the admission of air and to carry off any moisture that may have been driven in; openings into each of these flues are also to be made between the joists of the different floors for ventilation. Other methods of building such walls are described in Chap. III. Sect. II. *par.* 1902*c*.

2293*b*. Mason. All cramps to be of copper; iron cramps not to be allowed (see *par.* 2284*a*.). Lead joggles, and slab slate dowels to be inserted in the joints where directed.

The quoins, jambs, string-courses, hoodmoulds, buttress weatherings, copings, and dressings generally, to be strictly worked according to detail drawings, and to be dragged, chopped, tooled, or rubbed (according to the quality of the stone) so as to be truly worked in every particular.

All the tracery and mouldings to be set out full size, and cut and set to the right jointing as approved by the architect or the clerk of the works.

The caps and bases to piers to be in large stones. The caps and bases to dwarf shafts

MASON (2293*b*).

(if any), and the corbels under wall pieces or other roof timbers, to be well pinned into walls, and sunk and dowelled to receive shafts or timbers.

The tower and spire to be carefully carried out in accordance with detailed drawings. The spire to spring from squinch arches or from the solid broaches (or as the case may be), and gradually reduced towards the top, each stone to be wrought and cut to its through bed and inclination of its plane, the parts (as shown) to be in solid ashlar and carefully tailed and bonded. The bands, mouldings, cornices, strings, &c., to be worked as shown, and continued round; the storm lights to be formed with solid sills, heads, &c.; the vane to drop through the finial and to be securely fixed. The windows of the tower and the storm lights of the spire, to be grooved for louvres of wood or slates (or to be filled in with thin slabs of stone with ornamental piercings).

Turn relieving arches over all arches of nave, chancel, &c., formed of different coloured stones, arranged as directed, and form bands, diapers, crosses, &c., of same where shown. The stones for parti-coloured work to be Pennant, Caen, Temple Quiting, Red Forest of Dean, Silver Grey Forest of Dean, Red Mansfield, Whinstone, or Blue Warwickshire, stone (or local stone, if of suitable colour).

Provide shafts where shown of Derbyshire, Devonshire, Purbeck, or other marble, or of alabaster, serpentine, Aberdeen or Peterhead granite (or other as may be selected), to be well polished; and to be sunk, dowelled, and secured into caps and bases.

Shafts in angles of doorways (if any) to be of any suitable dark stone (if necessary) to contrast with the jamb.

Pave the entrance hall, passage, &c.; or if a church, pave the passages, porches, &c., where coloured on plan, with Minton's (or other) encaustic tiles, one third (or more or less) being figured, combined with chocolate and black tiles, value . . . . per yard superficial, manufacturers' prices. Pave the chancel (usually with richer tiles) with tiles value . . . . per yard superficial.

Face the walls of . . . . with Minton's glazed (or other) tiles, value . . . . per yard superficial, to be secured with cramps of stout copper wire inserted in holes in edges of the tiles.

All the tiles to be of the best quality, free from blemishes; to be set in Roman cement, and to have all cement removed from their face after the work is finished; the edges of the tiles to be rubbed, where necessary, to ensure neatness of workmanship, and care is to be taken that they are not injured by the workmen after they are laid.

The steps to the sanctuary and chancel to be of rubbed Portland, Red Mansfield, Robin Hood, Craigleith, or other hard stone or marble, in lengths of not less than 10 feet, very carefully set and bedded, pinned, joggle jointed, and run and plugged with lead, and back-jointed to receive tile paving.

The base mouldings of the tower, jambs and arches of the windows and doors throughout the building, and whatsoever parts are tinted . . . . upon the elevations, are to be of tooled or dragged masonry.

The plinths, eaves, string courses, and the labels over the windows and doors, are to be of Ketton (or other suitable) stone, finished with a dragged or tooled face.

Regularity in the quoin stones is not desired, but they may be worked and set in any reasonable scantling so as best to bond in, and harmonise with, the intermediate rubble. The upper beds of the stones to be laid with a slight inclination outwards, and as close as their nature will allow. Every precaution is to be taken to avoid risk of the settling of the work from imperfect beds and open joints. The work is to be carried up regularly all round the building. In the case of a church with a tower, the walls of the latter are to be specified, to be built up very slowly and without being bonded into those of the church, but are to have slip joints or chases worked in them for forming the connection; this is in all cases to be so free as to allow for the settlement of the masonry without injury to the work in the church walls: with this exception, no part of any wall is at any time to be raised more than three feet higher than another, during the progress of the works.

The walls of the tower of a church are to be built quite solid, and inverted arches are to be turned under all the large apertures therein. All flat headed apertures are to be covered with York (or other) lintels, of thickness proportionate to the width of the opening.

The coping of the gables to be of Bramley Fall or other stone that is not porous, worked as shown, and the apices of the (here enumerate which) gables to be surmounted by crosses worked in Ketton or other stone, according to drawing, set with copper dowels.

Walls with concrete cores. The external face to be built up in courses of hammered, scabbled, or sawn stone. The internal face to be built up in sawn (or other) ashlæ.

Mason (2293*b*).

or in rough brickwork, in English bond, or rubble if it is to be plastered. The body of the walls to be filled in with strong concrete, composed of 1 part of ground stone lime and 6 parts of clean sharp gravel, filling in interstices. At every 2 feet 6 inches in height a double course of bricks is to be set in mortar; and at every 8 feet 6 inches in height, a bonding through stone, from 10 inches to 1 foot 3 inches deep, is to be fixed. Stone chippings may be mixed with the gravel forming the concrete.

Kentish Rag. The Kentish rag to be of the best quality, from the quarries at Boughton, sound and free from hassock, laid in random courses, gulletted and pointed with dark mortar. A sufficient number of bond stones to be built in, one through stone (at least) to each yard superficial.

Bath Stone. To be the best Bath stone from Sumpsion's, Pictor's, or Randall and Saunder's Combe Down quarries (no Farleigh Down stone to be used), to be laid on its natural bed in all cases, and cleaned off when set. All plinths, bases, and other work for a height of 4 feet above the ground level to be of Box Ground stone.

Flint work. (Flint walling is of the following descriptions:—Rough, or as the flints are dug; random, or broken without any regard to regularity; split, so that they are true on the face and oval in form; or, split and squared, by which neat and square work is produced.) The walling is to be built in the soundest manner with . . . . flints (state which of the four descriptions is to be used), laid in mortar compounded of quick-setting stone lime and coarse sharp sand, free from loam; bricks, tiles, pebbles, &c., may be bedded in the centre or core of the wall. The long flints to be selected and laid as through stones, and the string-courses, &c., to be laid entirely through the thickness of the wall, so as to give additional bond. The work to be kept as dry as possible during the construction, to be protected by boards in wet weather, and to be covered in as soon as possible after completion. No grouting to be used. If the walling is faced with half-flints, care is to be taken in laying them to keep their upper surfaces as level as possible, to prevent rain driving into the centre of the wall; firmly pin up the lower bed with fragments.

Random walling of local stone. The stone for the walls generally is to be brought from . . . . (state the quarry), that for the foundations (unless brickwork is used for them) to be of large size; all those in the visible surface of the walls are to be carefully hammered, scabbled, or sawn (as the quality of the stone and nature of the work may require). All stone used in the main walls of the building to be of good scantling, and no very thin stone will be allowed in any part.

2293*c*. Carpenter and Joiner. The trusses of roofs are to be framed as shown, and of timbers of the scantlings respectively figured, or as here specified. They are to be mortised, tenoned, arched, notched, moulded, chamfered, and stopped, as shown on the detail drawings; and to be bolted and strapped with wrought iron straps, forged with ornamental ends; all bolts to have washers and nuts, notched as shown.

The curved ribs (if any) to be put together in (three) thicknesses, so as to break joint, to be wrought all over, and the joints to be tongued. These (three) thicknesses are to be screwed close together with long screws, and bolted with $\frac{1}{2}$-inch bolts between each joint. The centre thickness to be tenoned into the timbers on which it abuts. Tongue a bold 3-inch bead to underside of same.

The hammer-beams (if any) are to be cogged down upon the wall plates, and framed to the ribs, and bolted, as shown. The principals are to be notched and tenoned to the hammer-beams, and well spiked to ribs, and tenoned together and pinned at top. The collars (if any) are to be firmly tenoned into and spiked to principals. The purlins are to be notched down and housed into the principals on each side, and spiked. The king-post or queen-posts are to be framed in the usual manner.

All the timbers of the roofs exposed to view are to be wrought, and the angles moulded, or chamfered, or stop chamfered.

All roofs (if exposed to view) to be boarded above the rafters with $\frac{7}{8}$-inch wrought matched V jointed boarding, laid diagonally, and securely nailed to rafters and covered with (asphalted) felt (or specify, to lath on the top of rafters and plaster between the same). Lay battens 3 inches by 1 inch over the boarding or laths, on the back of every rafter, and on the battens lay 3 inch by 1 inch slating battens (or double oak tiling laths if the roof be tiled), fixed to a proper gauge for the sized slates required.

In churches, the floors under the seats are usually of wood, and require rebated and chamfered oak margins, 6 inches by 4 inches, laid flatwise, where they abut upon paved floors. These margins are to be mortised or dowelled to receive bench ends, and the wood floors to be kept 3 inches above the tile floors on which they abut.

CARPENTER AND JOINER (2293*c*).

The whole of the seating throughout to be formed as detail drawings, of good, well-seasoned, English oak (or otherwise), to be wrought, chamfered, and stopped, or moulded and cut, as shown or required; to be carefully framed and put together. The bench ends to be (at least) 3 inches thick, tenoned and pinned to the chamfered oak sill. The backs to have solid moulded oak capping. The seats to be $1\frac{1}{4}$ inches thick, and the book-boards to be 2 inches thick (fixed flat or sloping), edges chamfered, all to be well housed and cut into bench ends. Fix cut brackets not more than 4 feet apart, under the seats; and cut brackets, not more than 3 feet apart, under the book-boards. All the seats to be kept clear of the piers (if any).

Doors. Those on the exterior are to be 2 inch wrought, ledged, framed, and braced, folding (or other) doors, with stop chamfered, arched heads, stiles, rails, and braces, covered on the outside with $\frac{3}{4}$-inch wrought, tongued, and V jointed, oak boarding, hung to solid oak frame (or on hinge-hooks let into stone jambs), with strong, heavy, wrought iron mediæval hinges, and fastened with best rim dead lock cased with oak, and a heavy wrought iron latch with bold ornamental drop handle and plate, key-plate, &c., all wrought according to detail drawing (or a price to be stated for each article). The frames to be of oak, 6 inches by 4 inches, wrought, double rebated, stop chamfered, grooved, &c, tenoned into stone steps, and to have extra strong hooks on plates screwed to same.

For a dwelling house; the principal entrance door to be of deal $1\frac{1}{2}$ inches thick, framed flush, with V joints inside; the exterior to be cased with $\frac{3}{4}$-inch oak boards, with moulded fillets over the joints, the same to return round the head, and to die at bottom on an oak rail, 9 inches deep, sometimes having sunk quatrefoils, &c. The door to be hung on wrought iron ornamental hinges to hooks let into the jambs (or screwed to frames); an 8-inch rim lock and ornamental drop handle, escutcheon, and key-plate, and two 8-inch barrel bolts.

The back, or side entrance, door to be $1\frac{1}{4}$-inch, framed, ledged, and braced, covered with $\frac{3}{4}$-inch wrought oak boarding with chamfered joints, nailed on with rose nails driven through and clenched; hung on hinges and fastened with lock and bolts, similar to those specified for front entrance.

The internal doors may be of the following varieties:—

$1\frac{1}{2}$-inch four-panelled, with hollow on the room side, and $\frac{3}{4}$-inch diagonal V boarding next the hall or passage; to be hung with fleur-de-lys or ornamental wrought iron hinges, made to clasp the door so as to show on both sides, and fastened with wrought iron latches and ornamental drop rings.

$1\frac{1}{2}$-inch four-panelled, square framed, stop chamfered, filled in with upright or diagonal V jointed boarding, and hung on hinges as previously specified.

Cupboard fronts to correspond with the doors of their respective rooms, hung on ornamental S, HL, or other similar hinges, fastened with small tumbler locks, wrought iron key plates, and small twisted or other drop handles.

The *ceilings* of the principal rooms;—after they are plastered, to be divided into square panels about . . . feet square, by nailing thereon hollowed fillets $2\frac{1}{2}$ inches by 1 inch (or more), neatly scribed at intersections, with staff beads 1 inch (or more) diameter, nailed along the centre of the same, mitred at intersections, and conveyed round walls as a cornice. Care is to be taken in laying the joists so that they may form nailing points for these panel ribs.

The principal *staircase* to have $1\frac{1}{4}$-inch pitch pine (or other) treads, with rounded nosing and hollow moulding under same, and inch risers, glued and blocked to fir carriages; the ends of the steps to be housed into $1\frac{1}{4}$-inch wall strings, and 2-inch outer string boards, sunk and staff beaded, and finished at the top with a boldly moulded capping, framed at the bottom and corners into 6-inch square newels, with moulded finials, bases, and pendents, as drawing. Boldly moulded oak handrail, 4 inches wide and 6 inches deep, with $1\frac{1}{2}$-inch square oak balusters, stop chamfered.

The *landings* to be formed by joists resting upon boldly moulded stopped beams, as shown on sections.

The *tiled floor* (when laid on joists):—spike fillets to joists, at 3 inches below their upper surfaces; fill in between the same with inch rough boarding. The vacuity to be filled up with pugging of concrete flush with the upper surface, finished with a layer inch thick of Roman cement smoothly floated to receive the tiles.

2293*d*. PLASTERER. If the walls of a church are to be plastered, the stone jambs to windows and doors are usually specified to project one inch beyond the face of wall, so as to form a stop for plaster, and afterwards cleaned off and left flush.

Lath for, and plaster to, the spaces between the rafters (unless the boarding is intended to be left visible).

2293*e*. Slater or Tiler. Cover the *ridges* with socketed roll Staffordshire ridge tiles set in cement; the tiles to be grooved for cresting (if any). Cover the *hips* with proper lapping hip tiles or rolled hip tiles. Provide ornamental *tile cresting* (if any), and fix same on ridges where shown on elevations.

Cover the roofs with good sound plain tiles, combined with ornamental tiles, to form patterns, as shown; every tile to be pegged with a good English oak peg, and laid in mortar to a 3-inch lap.

Cover the roofs with best Bangor slates; the bands and diapers to be formed of Carnarvon or Westmoreland green, or other coloured slates; or courses to be laid of slates cut to a notched pattern.

The slater to provide slates to form damp-proof course in walls; and for the bottoms of hot water pipe channels (if any).

2293*f*. Smith. Provide and fix $\frac{1}{2}$-inch square saddle bars to all the windows, with lead lights; to be fixed on an average 12 inches apart.

Provide and fix to outside of windows, where necessary, 1-inch square stancheons, not more than 6 inches apart, with ornamental heads forged to drawing, let into (frames or) stone sill at bottom, and passed through saddle bars with mortises formed thereon.

For church windows with tracery heads, provide and build in across the springing of the arch of all windows of 3 lights and upwards, wrought iron bars 2 inches by $\frac{1}{2}$-inch, corked, and well turned up 2 feet from jambs, on each side; these bars to be well galvanized, and fixed with play for expansion or strain, in notches through the mullions.

Provide . . . . wrought iron hopper (or other) casements, and fix one to each light of each window (or as many as necessary). If hoppers are used they are to rest on the sill, and be hinged next to it, so that when closed the exterior glazing may be flush, and to be fitted with opening racks and fastenings.

Provide all requisite straps, bolts, nuts, and washers for the various roofs. Where visible, the straps are to be worked to detail drawings; and the washers and nuts to be notched and stamped as directed.

Provide and fix according to drawing, the wrought (or cast) iron vanes, crosses, ridge cresting, guards to areas, balconies, &c.; all to be securely fixed; the vanes and gable crosses to have stems as long as possible, and to be leaded into the stone or screwed to the roof timbers, as the case may be.

Provide and fix ornamental wrought iron hinges, latches, key-plates, closing rings, &c., on doors, as specified in carpenter's work, all to be strictly worked according to detail drawings.

Provide and fix an ornamental cast iron grating to pattern, to cover hot water pipe channels.

Provide and fix to all overhanging eaves 4-inch cast iron eaves gutter, with all necessary angle pieces, valley pans to internal angles, swan-necks, and socket pipes cast on the gutter to lead into heads of rain water pipes. The gutters to be fixed on strong wrought iron brackets screwed to the feet of the rafters; and the joints to be screwed together and bedded in red lead putty. Rectangular down pipes are now frequently used, with ornamental ears or bands.

Provide and fix Newall's (or other) copper wire lightning conductor with point, properly secured, to . . . . (the highest portion of the building), and brought down with all requisite insulators; the end to be carried into the earth for a depth of 3 feet from the surface.

2293*g*. Glazier. Glaze all the windows (of the church) and tracery heads (if any) with quarries and borders in strong church lead $\frac{3}{8}$-inch wide. The lead to be secured to the saddle bars and stancheons with strong copper wire, soldered to lead, and securely twisted round the saddle; the glazing to be properly cemented, to be let into the grooves of stonework, and neatly pointed with lime and stone dust.

The glass to be Powell's quarries, or Hartley's patent rough cathedral glass, $\frac{1}{8}$-inch thick. The quarries to be of one tint, and the borders of another tint (as for instance, green and yellow).

Skylights and windows, in exposed situations, where much light is not required, may be glazed with Hartley's rough plate glass, $\frac{1}{4}$-inch thick, or less.

Water-closet and similar windows (where privacy is desired), with Hartley's patent rough plate glass, $\frac{1}{8}$-inch thick; with fluted glass; or with diapered, or with embossed glass.

Any other windows to be glazed with ribbed, enamelled, embossed, or stained glass must be enumerated.

Provision to be made in window sills and skylights (where practicable), for conveying condensed water to the exterior of the building.

2293*h*. PAINTER. Stop with coloured stopping, twice oil with linseed oil, and twice varnish with best copal varnish, the exterior doors and frames.

Stop with stained stopping, and knot with coloured knotting, the wrought woodwork of roofs; brush the whole twice with boiled oil, and once varnish the same. Pick out the chamfers and mouldings in roofs with vermillion, cobalt blue, chocolate, pale yellow, and white, in two oils, and stencil patterns thereon, according to drawing.

Deal seats, or benches, are to be knotted with stained knotting, stained with .... stain (approved by the architect), and twice varnished with tackless varnish.

In a dwelling house;—all the wrought woodwork (except the floors, and the work executed in oak) to be stained with .... stain, once coated with linseed oil, and twice varnished with the best copal varnish. Or, if the deal has been picked, it may be left plain, and only varnished. Or, if selected with much care, the deal and pine may be polished. Inside *oak* work is best left to obtain an effect by use, but where immediately desirable, it may be once or twice oiled.

Pick out the ornamental ironwork on doors, roofs, screens, &c., in black or dark blue. A pattern or diaper is sometimes done in gold leaf upon it.

All paint and varnish to be of the best quality; sizing and mineral turpentine will not be allowed.

2293*i*. BELLHANGER. The front (and side) entrance doors to have bold pendant mediæval wrought iron pull, according to detail drawing.

The pulls in the principal rooms to be bronze or iron lever pulls of mediæval character, and very strong; the wire of strong copper, to be conveyed in zinc secret tubing; the cranks to be best horn cranks. Floor boards over bell wires to be screwed (not nailed) down for ready removal.

2293*j*. GAS FITTER. Lay on from the main, strong wrought iron welded tubing of the necessary diameter, with all necessary bends; junctions, stopped ends, T pieces, &c.

Provide and fix in each of the principal rooms a pendent corona of . . . lights, value . . *s*. each, fitted with balance weights and a ball and socket joint. Fix bronzed (or brass) bracket burners in passages (or where else required), value . . *s*. each.

Church lights are of wrought iron, bronze, or brass, standards, coronæ, brackets, &c., according to their situations, for gas or for candles (specify value of each).

All lights to be fitted with argand, fish-tail, or batswing burners. Ground glass, or figured glass globes, where stated, are sometimes included by the architect.

2293*k*. We now close this general outline of a specification (which has been submitted as nothing more than a skeleton for filling up as different cases may require) by adding a general form of a contract, with the usual conditions. This requires as much variation to meet each particular case, as does the specification.

2294. CONDITIONS. That all the works shall be executed in the best and most workmanlike manner, to the satisfaction of [Here add employer's name], or his architect, without reference thereon to any other person. If any alterations should hereafter be made by order of (*the employer*), or his architect, by varying from the plans or the foregoing specification, either in adding thereto or diminishing therefrom, or otherwise however, such alterations shall not vacate the contract hereby entered into, but the value thereof shall be ascertained by the said architect, and added to or deducted from the sum hereinafter mentioned, as the case may be; nor shall such alterations, either in addition, diminution, or otherwise, supersede the condition for the completion of the whole of the works, but the contractor shall, if such alterations, of whatever sort, require it, increase the number of his workmen, so that the same, as well as the works contained in the above particulars, shall be completely finished, and so delivered up to (*the employer*), on or before the day of , in the year , on failure whereof the contractor shall forfeit and pay to (*the employer*), the sum of for every day that the work remains unfinished and undelivered as aforesaid, which sum the said (*the employer*) shall be allowed to stop as liquidated damages out of any moneys that may be due and owing to the said contractor on account of the works.

If any doubt or doubts should arise during the execution of the works, or at measuring the extras should any occur, or at making out the accounts as to any extras or other works for which the contractor may consider he may have a claim, over and above the sum hereinafter mentioned, the admission and allowance of any such claim or claims shall be judged of, determined, and adjusted solely by the architect to (*the employer*), without reference in any way to any other person; it being the intention of these conditions that all such works of every kind that may be necessay for completely finishing the works proposed, for the rectification of any failure from whatever cause arising, and the well maintaining, sustaining, and supporting the whole of the works, as well as alterations and additions, should such be made, so that the whole may remain sound and firm, are implied in the foregoing specification, although the same may not therein be specifically expressed.

If the contractor shall neglect or refuse to carry on the works with such dispatch as is thought proper by the architect, it shall be lawful for (*the employer*) or his architect, and either of them is hereby empowered to employ such other person or persons as (*the employer*) or his architect, or either of them, may think fit or necessary, to finish and complete the several unfinished works, after having given notice thereof in writing six days before employing such person or persons, such notice to be left either at the contractor's shop, counting-house, or usual place of abode, without effect, and the amount or amounts of the bill or bills of any artificers that may be so employed shall be deducted out of any moneys that may be due and owing to the said contractor, or any part thereof, as the case may be.

It is hereby agreed, this day of , in the year , between (*the employer*), on the one part, and (*the contractor*) on the other part, that he, the said (*the contractor*), for his executors, administrators, and assigns, doth hereby promise and agree to and with the said (*the employer*), to do and perform all the works of every kind mentioned and contained in the foregoing particulars, and according and subject to the conditions above recited, and according to the plans prepared and referred to, at and for the sum of pounds; and the said (*the contractor*) doth hereby agree to abide by and be subject to the several clauses, conditions, and penalties hereinbefore mentioned and contained.

In consideration whereof the said (*the employer*) doth hereby promise and agree to pay to the said (*the contractor*), on the certificate of the architect, the aforesaid sum of pounds, in separate payments, it being agreed that neither of the said payments, except the last, shall amount to more than two-thirds of the value of the work done at the time of such certificate being given.

In witness whereof the said parties have hereunto set their hand, the day and year above written.

A. B. (the employer.)
Witness, E. F. C. D. (the contractor.)

Sect. XIV.

MEASURING AND ESTIMATING.

2295. The practice of measuring is dependent on rules already given under Mensuration, in Sect. VI. Chap. I. of this Book (1212, *et. seq.*), in which are described the methods of ascertaining the superficial and solid contents of any figure. The application of them to architecture, in the practice of measuring and estimating the different parts of a building, forms the subject of this section.

2296. For the purposes of measuring, the common instruments are a pair of 5-feet rods, divided into feet, inches, and half inches, and a 2-feet rule divided into inches and eighths and twelfths of inches, beyond which subdivision, measurements are rarely carried in this country.

2297. The mode of what is called squaring dimensions, as usually practised by duodecimals, will be now explained.

2297*a*. Duodecimals are a series of denominations beginning with feet, wherein every inch in the lower denomination makes twelve in that next above it; they form a series of fractions, of which the denominations are understood, but not expressed. The dimensions are taken in feet, inches, and twelfths of an inch, but not nearer, except in works of the greatest nicety. Feet and inches are marked with their initial letters, but twelfths or seconds by a double accent, thus 2″, and thirds by a triple accent, thus 5‴.

2297*b*. To multiply duodecimals together, write down the two dimensions to be multiplied in such way that the place of feet may stand under the last place of the multiplicand; begin with the right hand denomination of the multiplier, and multiply it by every denomination of the multiplicand, throwing the twelve out of every product, and carrying as many units as there are twelves to the next. Placing the remainders, if any, under the multiplier, so that the like parts in the product may be under like parts of the multiplicand, proceed with every successive figure of the multiplier towards the left, in the same manner, always placing the first figure of the product under the multiplier. Then the sum of these partial products will be the whole product. In duodecimals there will be as many denominations below feet as in both the factors taken together.

Example 1.—Multiply 7 ft. 5 in. by 3 ft. 4 in.

7 : 5	
3 : 4	
2 : 5 : 8	
22 : 3	
24 : 8 : 8	

Example 2.—Multiply 24 ft. 8 in. 8″ by 3 ft. 7 in.

24 : 8 : 8	
3 : 7	
14 : 5 : 0 : 8	
74 : 2 : 0	
88 : 7 : 0 : 8	

2297*c*. In example I. there is only one place of duodecimals in each factor; there are therefore two places in the product. In the second example there are two places of duodecimals in the multiplicand and one in the multiplier, which make, together, three; there are therefore three denominations in the product. This method of placing the denominations of the factors gives the correct places of the product at once; since like parts of the product stand under like parts of the multiplicand. It also shows the affinity between duodecimals, decimals, and every series or scale of denominations whereof any number divided by the radix of the scale makes one of the next towards the left hand. The consideration is, moreover, useful in discovering readily the kind of product arising from the multiplication of any two single denominations together.

2297*d*. When the number of feet runs very high in the factors, it will be better to write down the product of each multiplication, without casting out the twelve, and add together those of each denomination beginning on the right, and divide by 12, to carry to the next higher place, then add these, and so on, as often as there are places in the whole product.

Example.—Multiply 262 ft. 5 in. by 54 ft. 8 in.

262 : 5
54 : 8
2099 : 4
1048 : 20
13100 : 250
$197 = \frac{2369}{12}$
14345 : 5 : 4

Thus, under inches, the products being set down and added, they amount to 2369, which, divided by twelve, gives 197 to carry to the place of feet, and 5 remainder. Then adding the feet together with the quantity carried, it gives the whole number of feet; while the operation is extremely simple and free from the troubles of either side operations or useless stress on the memory.

2297*e*. The division of the foot into 12 parts renders the application of the rules of *practice* very valuable in the computation of duodecimals. The practical rule is to set down the two dimensions one under the other, that is, feet under feet and inches under inches, and multiply each term in the multiplicand by the feet in the multiplier, beginning at the lowest; and, if the numbers be large, put down the inches without carrying 1 for every 12 from inches to feet. Then, instead of multiplying by the inches, take such aliquot parts of the multiplicand as the inches are of a foot; after which add the lines together, carrying 1 for every 12 inches.

Example 1.—Multiply 7 ft. 5 in. by 3 ft. 4 in.

4 in. $= \frac{1}{3}$. 7 : 5
3 : 4
22 : 3
2 : 5 : 8
24 : 8 : 8

Example 2.—Multiply 262 ft. 5 in. by 54 ft. 8 in.

8 $= \frac{2}{3}$. 262 : 5
54 : 8
1048 : 270
1310
87 : 5 : 8
87 : 5 : 8
$23 = \frac{281}{12} : 4$
14345 : 5 : 4

The same examples have been used to show the relative advantages of the two methods.

2297*f*. Thus far we have treated of the squaring of dimensions to obtain the superficies of work. To learn the solidity of certain materials, such as timber, stone, and some others, the dimensions have to be cubed. The process is similar to the above, and is continued a further step. One example will suffice to explain the method, and we will take the figures given in the above system.

Example.—What is the cube of a block of stone, 7 ft. 5 in. wide, 3 ft. 4 in. thick, and 2 ft. long?

7 : 5
3 : 4
22 : 3
2 : 5 : 8
24 : 8 : 8 super.
12
296 : 8 : 0 cube.

2297*g*. The abridgment of the labours of practical men is always a matter of importance—being identical with the saving of time which is lost in calculation, and which with the architect is of the utmost importance, when it is recollected what multifarious duties he has to discharge. Hence the following table of squares, cubes, and roots of numbers, up to 1000, will be most acceptable to him. The first column of the table shows the number, the second the square of such number, the third exhibits its cube. In the fourth column is found the square root of the number, and in the fifth its cube root. Thus, looking to the number 61 in the first column, its square is found to be 3721, its cube 226981, its square root 7·8102497, and its cube root 3·936497. Again, taking the number 784, we find its square to be 614656, its cube 481890304, its square root 28, and its cube root 9·220872.

2297*h*. A *power* is that number which is obtained by multiplying a number several times by itself. A square is the number multiplied by itself; a cube by multiplying it twice by itself. The square is called the second power; the cube is called the third power; when multiplied again by itself it becomes the fourth power, which is commonly called the *bi-quadrate*; and so on:—

Power,	Of No. 2.	Of No. 3.	Number.	4th Power.	5th Power.
I.	2	3	1	1	1
II. or	square 4	or square 9	2	16	32
III. or	cube 8	or cube 27	3	81	243
IV.	16	81	4	256	1,024
* V.	32	243	5	625	3,125

X.	1,024	59,049	10	10,000	100,000
XI.	2,048	177,147	11	14,641	161,051

2297*i*. We shall now at once proceed to the general principles on which the measurement and estimation of work in the several artificers' departments are conducted.

2298. Digging is performed by the solid yard of twenty-seven cubic feet (that is, 3 feet × 3 feet × 3 feet = 27 feet). Where the ground is soft in consistence, and nothing more is necessary beyond cutting with a spade, a man may throw up a cubic yard per hour, or 10 cubic yards in a day; but if of firmer quality, *hacking* becomes necessary, and an additional man will be required to perform the same work; if very strong gravel, more assistance will be required. If, therefore, the wages of a labourer were 2*s*. 6*d*. per day, the price of a yard would be 3*d*. for cutting only, without profit to the contractor; 6*d*. for cutting and hacking, and 9*d*. if two hackers be necessary. In sandy ground, where wheeling becomes necessary, three men will remove 30 cubic yards in a day to the distance of 20 yards, two for filling and one for wheeling. But to remove the same quantity in a day to a greater distance, an additional man for every 20 yards will be required.

2299. The method of ascertaining the quantity of excavation will, of course, be obvious; the quantity is the length multiplied into the depth and width. In the cases of trenches merely dug for the reception of walls, which, of course, are sloped to prevent the earth falling in on the excavators, a mean width is to be taken. Thus, suppose an excavation 24 feet long, 4 feet wide at top, and 2 feet at the bottom (average width therefore 3 feet), and 5 feet deep, we have for the quantity of yard $\frac{24\times3\times5}{27}=13{\cdot}33$ cube yards.

2300. Brickwork. In measuring and estimating the value of brickwork, the following points must be remembered. A rod of brickwork is a mass $16\frac{1}{2}$ feet square; hence the quantity of superficial feet which it contains is $272\frac{1}{4}$ feet ($16{\cdot}5\times16{\cdot}5$), but the $\frac{1}{4}$ of the foot is too trifling to make it worth while to embarrass calculations with it, and consequently 272 feet is universally taken as the superficial standard content of a rod. Its standard thickness is one brick and a half (or $13\frac{1}{2}$ inches). Hence it follows, that a cubic rod of brickwork would be 272 feet × $13\frac{1}{2}$ inches = 306 feet cube. The allowance for the number of bricks is taken on an average at 4500. Much, however, depends on the closeness of the joints and the nature of the work. In walling, a reduced foot is generally taken as requiring 17 bricks; a foot superficial in Flemish bond, laid in malm facing, about bricks; and a foot superficial of gauged arches, 10 bricks. In paving, a yard requires 8 paving bricks, or 48 stock bricks, or 144 Dutch clinkers laid on edge, or 36 bricks laid flat.

2301. In tiling, which is measured by the square of 100 superficial feet, a square will require 800 at a 6-inch gauge, 700 at a 7-inch gauge, and 600 at an 8-inch gauge. The gauge necessarily regulates the distance of the laths, and, at the same time, must be dependent on the slope of the roof, which, if flat, should not be less than 6 inches, as for instance, above the kerb in a kerb roof; and not more than 8 inches in any case. A square of plain tiling requires about on an average a bundle of laths, two bushels of lime, and a of sand, and at least a peck of oak pins. The laths are sold in bundles of 3, 4, and 5-feet lengths. A bundle of the 3-feet contains eight score, the 4-feet six score, and the 5-feet five score to the bundle. The nails used are fourpenny; they are purchased by the long hundred, that is, of six score, and, in day work, are charged by the bricklayer 5-score to the hundred. The name of nails, as fourpenny, fivepenny, &c., means fourpence, fivepence, &c. per hundred. The number of nails required for a bundle of 5-feet and 6-feet laths, are 500 and 600 respectively.

2302. A square of pantiling requires 180 tiles laid at a 10-inch gauge, and a bundle of 12 laths 10 feet long.

2303. In lime measure, what is called a hundred is 100 pecks, or 25 striked bushels (old measure).

2304. In sand measure, 18 heaped bushels, or 21 striked bushels, equal to 1 yard cube, is a single load, and about 24 cubic feet 1 ton.

2305. In mortar 27 cubic feet make 1 load, which on common occasions contains half a hundred of lime with a proportional quantity of sand. Eleven hundred and thirty-four cubic inches make a hod of mortar; that is, a mass 9 inches wide, 9 inches high, and 14 inches long. Two hods of mortar are nearly equal to half a bushel. The following measures and weights it may be also useful to remember: —

23½ cubic feet of sand = 1 ton; hence 1 cubic foot weighs 95·3 lbs.

17½ cubic feet of clay = 1 ton; hence 1 cubic foot weighs about 130 lbs.

18 cubic feet of common earth = 1 ton; hence 1 cubic foot weighs nearly 124 lbs.

306 cubic feet of brickwork = 13 tons; hence 1 cubic foot is equal to full 95 lbs.

2306. In the measurement of brickwork, from the surface being 272 feet and the standard thickness 1½ brick, it will be immediately seen that nothing more is requisite than, having ascertained the thickness of each part of the work, to reduce it to the standard thickness above stated, and this will be found sufficiently easy in almost all cases. Where, however, this cannot be done, we can always ascertain with sufficient accuracy the cubic contents in feet of any mass of brickwork; and dividing by 306 we have the number of rods.

2307. We here present an illustration in a wall of the most common occurrence (*fig.* 808.), which we will suppose 20 feet long without reference to any wall which might return from it, and thus diminish its length in measuring therewith a *returning wall*. The following is the method of entering and calculating the dimensions.

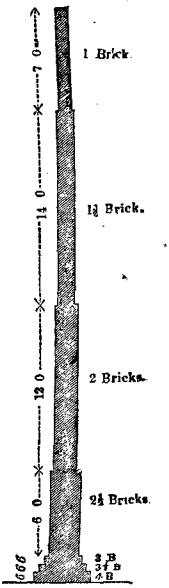

Fig. 808.

	Length multiplied by the Height.	Area.	Number of Bricks in Thickness.	Factors to reduce the Area to Standard of 1½ Brick.	Thickness reduced to 1½ Brick in Feet sup.
Footings 6 courses	20·0 × 6	10·0	4	2⅔	26·8
	20·0 × 6	10·0	3½	2⅓	23·4
	20·0 × 6	10·0	3	2	20·0
Basement wall	20·0 × 6·0	120·0	2½	1⅔	200·0
Ground-floor wall	20·0 × 12·0	240·0	2	1⅓	320·0
One-pair wall	20·0 × 14·0	280·0	1½	1	280·0
Two-pair wall	20·0 × 7·0	140·0	1	⅔	93·4
					963·4

Therefore the total is 963·4 superficial feet 1½ brick thick, and $\frac{963}{272}$ = 3 rods, 147 feet.

2308. Upon this principle the measuring and estimation of brickwork is conducted, and having the price and quantity of bricks in a rod, and the lime, sand, and labour, which will presently be given, we may come to a pretty accurate knowledge of its value. But there are other articles which will require our attention, to which we shall presently advert. Before proceeding, however, we may as well observe that the above result of 3 rods 147 feet might have been similarly obtained by cubing the mass of brickwork and dividing the whole mass by 306, but with much more labour.

2309. In measuring walls faced with bricks of a superior quality, the area of such facing must be measured, or allowance extra is made in the price per rod of the brickwork.

2310. All apertures and recesses from any of the faces are deducted.

2311. Gauged arches are sometimes deducted and charged separately, sometimes not; but whether deducted or not does not signify, as the extra price must be allowed in the latter case and the whole price in the former. Rubbed and gauged arches, of whatever form, are measured and charged by the superficial foot.

2312. The angles of groins, outside and inside splays, bird's mouths, bull's noses, are measured by the lineal or running foot; but cuttings are measured by the foot superficial. Chimneys are measured solid to allow for the trouble of forming and pargetting the flues. The opening at bottom, however, is to be deducted.

2313. Quarters in bricknogging are measured in, as are all sills, stone strings, and timber inserted in walls. Two inches are also allowed in the height of brickwork for bedding plates if no brickwork be over them.

2314. Ovens, coppers, &c. are measured as solid work, deducting only the ash holes; but all fire stone, Welsh lumps, tiles, &c., though measured alone, are not to be deducted out of the brickwork. Pointing, colouring, &c. to fronts, is measured by the foot superficial. Plantile creesing by the foot lineal.

To estimate the value of a rod of brickwork, the method is as under: —

	£	s.	d.
4500 stocks, at per thousand - - - - -	0	0	0
1½ hundred of lime = 37½ striked bushels containing 27 feet cube to the hundred - - - - - - - - -	0	0	0
2 loads of sand - - - - - - - - -	0	0	0
Labour and scaffolding - - - - - - - -	0	0	0
	0	0	0
Per cent. profit - - - - - - -	0	0	0
Per rod - - - - - - - -	0	0	0

2315. In measuring and estimating all sorts of artificers' works, the method usually adopted for saving labour in making out the account is to arrange in separate columns each sort of work, and then to add them up and carry the total to the bill. In brickwork, where walls are of different thicknesses, these with their deductions are arranged in separate columns, and then all are reduced to the standard thickness.

2316. The common measure for tiling is a square of 10 feet, containing therefore 100 feet superficial. Claims are made for the eaves to the extent of 6 inches; but in pantiling this ought not to be allowed, as a claim not founded in justice, though custom is pleaded for it.

2317. The following table shows the number of bricks necessary for constructing any number of superficial feet of walling from 1 to 90,000, and from half a brick to 2½ bricks thick; and thence, by addition only, to any thickness or number required, at the rate of 4500 bricks to a reduced rod. Thus, if it be required to find the number of bricks wanted to build a piece of work containing 756 feet super. of walling 1½ brick thick, we find by inspection for 700 feet 11580 bricks; for 50 feet, 827 bricks; and for 6 feet, 99 bricks; in all, 11580 + 827 + 99 = 12506.

Table showing the requisite Quantity of Bricks for a given Superficies of Walling.

10000	75000	70000	65000	16666⅔	15000	13333⅓

The use of the foregoing tables it can scarcely be necessary to explain, They are such as to indicate, on inspection, their value; and we shall therefore leave them without further comment for their application.

2322. When work is performed by the day, or the materials used are to be numbered, as ofttimes necessarily occurs, fire bricks, red rubbers, best marle stocks for cutters, second best ditto, pickings, common bricks, place bricks, paving bricks, kiln-burnt bricks, and Dutch clinkers are charged by the thousand.

2323. Red rubbers, kiln and fire-burnt bricks, are also charged by the hundred. Foot tiles and ten inch tiles are charged either by the thousand or hundred.

2324. Sunk foot tiles and ten-inch tiles with five holes, now never used in the south of England, are charged by the piece.

2325. Pantiles, plaintiles, and nine-inch tiles are charged by the thousand.

2326. Oven and Welsh oven tiles, Welsh fire lumps, fire bricks, and chimney pots are also sold by the piece.

2327. Sand, clay, and loam are charged by the load; lime sometimes by the hundred weight; but the *hundred* of 100 pecks is the more usual measure in and about the metropolis. Dutch terras is charged by the bushel, which is also sometimes the measure of lime. Parker's cement is similarly charged.

2328. Pantile and plaintile laths are charged by the bundle or load; hair and mortar by the load; hip hooks and T tiles by the piece.

2329. Neither here, nor in the following pages, is it intended to convey to the reader more than the principles on which an estimate is founded. The prices of materials are in a state of constant fluctuation; and though when we come to the consideration of the prices of joiner's work, we intend, from the ingenious computations of Mr. Peter Nicholson, to give something approaching a constant value from the known performance of a good workman, it is to be recollected by the student, that cases so vary as to make it impossible to give a list of prices and value, that would be of any value at the period of a month from the time of his reading this paragraph. The details of prices he must constantly watch if he intends to do justice to his employer.

CARPENTRY AND JOINERY.

2330. The works of the CARPENTER are the preparation of piles, sleepers, and planking, and other large timbers, formerly much, but now rarely, used in foundations; the centering on which vaults are turned; wall plates, lintels, and bond timbers; naked flooring, quarter partitions, roofing, battening to walls, ribbed ceilings for the formation of vaulting, coves, and the like in lath and plaster, posts, &c.

2331. In large measures, where the quantity of materials and workmanship is uniform, the articles are usually measured by the square of 100 feet. Piles should be measured by the foot cube, and the driving by the foot run according to the quality of the ground into which they are driven. Sleepers and planking are measured and estimated by the foot, yard, or the square.

2332. Plain centering is measured by the square; but the ribs and boarding, being different qualities of work, should be taken separately. The dimensions are obtained by girting round the arch, and multiplying by the length. Where groins occur, besides the measurement as above, the angles must be measured by the foot run, that is, the ribs and boards are to be measured and valued separately, according to the exact superficial contents of each, and the angles by the linear foot, for the labour in fitting the ribs and boards, and waste of wood.

2333. Wall plates, bond timbers, and lintels are measured by the cubic foot, and go under the denomination of *fir in bond.*

2334. In the measurement and valuation of naked flooring, we may take it either by the square or the cube foot. To form an idea of its value, it is to be observed, that in equal cubic quantities of small and large timbers the latter will have more superficies than the former, whence the saving is not in proportion to the solid contents; and the value, therefore, of the workmanship will not be as the cubic quantity. The trouble of moving timbers increases with their weight, hence a greater expenditure of time; which, though not in an exact ratio with the solid quantity, will not be vastly different, their sections not varying considerably in their dimensions. As the value of the saving upon a cube foot is comparatively small to that of the work performed by the carpenter, the whole cost of labour and materials may be ascertained with sufficient accuracy when the work is uniform.

2335. When girders occur in naked flooring, the uniformity of the work is thereby interrupted by the mortices and tenons which become necessary; thus the amount arising from the cubic quantity of the girders would not be sufficient at the same rate per foot as is put on the other parts, not only because of the difference of the size, but because of the mortices which are cut for the reception of the tenons of the binding joists. Hence, for

valuing the labour and materials, the whole should be measured and valued by the cubic quantity, and an additional rate must be put upon every solid foot of the girders; or, if the binding joists be not inserted in the girders at the usual distances, a fixed price must be put upon every mortice and tenon in proportion to their size. The binding joists are not unfrequently pulley or chase-morticed for the reception of the ceiling joists; sometimes they are notched to receive the bridging joists on them, and they should therefore be classed by themselves at a larger price per foot cube, or at an additional price for the workmanship, beyond common joisting. All these matters must be in proportion to the description of the work, whether the ceiling joists be put in with pulley mortices and tenons, or the bridgings notched or adzed down.

2336. Partitions may be measured and estimated by the cube foot; but the sills, top pieces, and door heads should be measured by themselves, according to their cubic contents, at a larger price; because not only the uniform solidity, but the uniform quantity, of the workmanship is interrupted by them. The braces in trussed partitions are to be taken by the foot cube at a larger price than the common quartering, on account of the trouble of fitting the ends of the uprights upon their upper and lower sides, and of forming the abutments at the ends.

2337. All the timbers of roofing are to be measured by the cubic foot, and classed according to the difficulty of execution, or the waste that occurs in performing the work. Common rafters, as respects labour, are rated much the same as joists or quarters; purlins, which require trouble in fitting, are worth more, because on them are notched down the common rafters. The different parts of a truss should, to come accurately at the true value, be separately taken, and the joggles also separately considered, including the tenons at the ends of the struts; morticing tie beams and principals, forming the tenons of the truss posts, morticing and tenoning the ends of the tie beams and principals, are in another class. The strapping is paid for according to the number of the bolts. Common or bridging rafters' feet are also to be considered; the size and description of the work being always matter for the consideration of the architect.

2338. It is usual and fair to measure the battening of walls by the square, according to the dimensions and distances of the battening.

2339. Ribbed ceilings are taken by the cubic quantity of timber they contain, making due allowance for the waste of stuff, which is often considerable. The price of their labour is to be ordered by the nature of the work, and the cubic quantity they contain.

2340. Trimmers and trimming joists are so priced as to include the mortices and tenons they contain, and also the tenons at the extremities of the trimmers. But to specify all the methods required of ascertaining the value of each species of carpenter's work would be impossible, with any respect to our limits. They must be learned by observation; all we have to do is with the principles on which measuring and estimating is conducted.

2341. When the *carcass* of the building is completed, before laying the floors or lathing the work for receiving the plastering, the timbers should be measured, so that the scantlings may be examined and proved correct, according to the specification; and in this, as a general rule, it is to be remembered that all pieces having tenons are measured to their extremities, and that such timbers as girders and binding joists lie at least 9 inches at their ends into the walls, or $\frac{1}{3}$ of the wall's thickness, where it exceeds 27 inches. In the measurement of bond timber and wall plates, the laps must be added to the net lengths. If a necessity occur for cutting parallel pieces out of truss posts (such as king or queen-posts), when such pieces exceed 2 feet 6 inches in length, and $2\frac{1}{2}$ inches in thickness, they are considered as pieces fit for use, deducting 6 inches as waste from their lengths.

2342. The boarding of a roof is measured by the square, and estimated according to its thickness, and the quantity of boards and the manner in which they are jointed.

2343. Where the measurement is for labour and materials, the best way is, first, to find the cubical contents of a piece of carpentry, and value it by the cubic foot, including the prime cost, carting, sawing, waste, and carpenter's profit, and then to add the price of the labour, properly measured, as if the journeyman were to be paid. It is out of the question to give a notion of any fixed value, because it must necessarily vary, as do materials and labour; hence no tables or price-books are ever to be depended upon; they gull the unwary, and mislead the amateur who consults them. The only true method of forming a proper estimate is dependent on the price of timber and deals, for which general tables may be formed, and some will be presently given.

2344. It is, perhaps, unnecessary to repeat that a load of fir timber contains 50 cube feet: if, then, we know the price of the load in the timber merchant's yard, we may approximate the value of a cube foot as under. We will suppose the price to be, at the moment of estimating, 4*l.* 10*s.* per load. We shall then have—

	£	s.	d.
Prime cost of a load of fir	4	10	0
Suppose the cartage (dependent on distance)	0	5	0
Sawing into necessary scantlings	0	10	0
	5	5	0
Waste in converting equal to 5 feet, at $2\frac{1}{10}$ s. per foot, the load being 105s.	0	10	6
	5	15	6
20 per cent. profit on 5l. 15s. 6d.	1	3	0
	£6	18	6

2345. Now, $\frac{6l.\ 18s.\ 6d.}{50} = 2{\cdot}77$ shillings, or 2 shillings and 9 pence and nearly 1 farthing per foot cube.

2346. It is only in this way that we can arrive at the value of work; and it is much to be regretted that from no species of labour of the carpenter have been formed tables capable of furnishing such a set of constants as would, by application to the rate of a journeyman's wages, form factors, or, in other words, furnish data for a perpetual price-book. As we have before hinted, the best of the price-books that have ever been published are useless as guides to the value of work. The method of lumping work by the square is as much as possible to be avoided, unless the surfaces be of a perfectly uniform description of workmanship; as, for instance, in hipped roofs, the principal trouble is at the hips, in fitting the jack rafters, which are fixed at equal distances thereon; hence such a price may be fixed for the cubic quantity of hips and valleys as will pay not only for them, but also for the trouble of cutting and fixing the jack rafters. Such parts, indeed, as these should be separately classified; but the analysis of such a subject requires investigation of enormous labour; and as it must depend on the information derived from the practical carpenter, is, we fear, not likely to be soon, if ever, accomplished.

2347. Mr. Peter Nicholson, a gentleman to whom the architect as well as the practical man are more indebted than to any other author on this subject, is the only person who has attempted to promulgate a system founded on the scientific basis to which we have just alluded; and we have much pleasure in here alluding to the value of his labour, and of placing before the reader *the extent* to which he carried it, regretting much that he did not further pursue an investigation, which we have carried to a greater extent, though not now so complete as we could have wished.

2348. It is manifest that if the average time of executing each species of work were known, no difficulty could exist in fixing uniform rates of charge for it; but, as we have observed, the parties who could best instruct us on the subject are those most interested in withholding such information as would be required for the purpose. We shall now proceed to the question, premising that, for the present, we are only dealing with the cost of labour, that of the materials being a simple affair, as we have already seen in the case of ascertaining the value of a cubic foot of fir, and as we shall hereafter see in ascertaining the value of superficial feet of deals of any thickness.

2349. In the subjoined tables, the price is represented by the days, or decimal parts of a day, in which one man can perform the quantity of that sort of work, against which such price is affixed. Hence, knowing the rate per day of such man's wages, it forms a factor by which the value of the labour of such quantity of work will be estimated. We begin by centering.

Centering.

For plain cylindric vaults, fixed per square	2·033 days.
For groins of cylindric vaults, fixed per foot super.	·057
For guaged brickwork, per foot super.	·073
For brick trimmers bridgewise, per foot super.	·041
For coach-head trimmers, per foot super.	·057
For apertures, per foot run	·02

2350. To apply this to practice, we will take the first article in the table, that of the centering of a cylindric vault, a square whereof, we see, will occupy a man 2·033 days to make and fix. Now, supposing such man's wages to be 5s. per diem, we have only to multiply 2·033 by 5s. = 10·165, or nearly 10s. 2d. for a square of such work. The other items being similarly used, will give the results whereof we are in search.

The next table is one composed of several miscellaneous articles, and is as follows: —

Fir in bond and wood bricks, at per foot run	·008 day.
Fir in templates, lintels, and turning pieces, at per foot run	·025
Planing fir, from the saw, per foot super.	·017
Rebating fir up to 2 in. by $\frac{3}{4}$	·025
Rebating fir from 2 in. by $\frac{3}{4}$ to 3 in. by $1\frac{1}{4}$	·041

Single beading, up to ¾ inch - - - - - ·008 day.
Single quirk beading, from ¾ inch to 1¼ - - - - ·012
Return beads, worth double.

The next table is for quarter partitions: —

Common 4-inch, per square - - - - - 1·033 days
Common 5-inch, per square - - - - - 1·113
Common 6-inch, per square - - - - - 1·307
Common 6-inch, circular plan, per square - - - 1·888
Common trussed frame, with king-post, per square - - 1·743
Common trussed frame, with king and queen-posts, per square 2·226

The subjoined is a table for naked flooring: —

Ceiling floor, framed with tie beams, binding and ceiling joists, fixed per square - - - - - - - - 1·355 days.
Ceiling floor, with tie beams and ceiling joists only, fixed per square - - - - - - - - 1·065
Ceiling joists only, fixed per square - - - - ·646
Single-framed floor, trimmed to chimney, and well holes less than 9 inches deep, fixed per square - - - - - 1·355
The same, above 9 inches deep, fixed per square - - - 1·646
The same, if trimmed to party walls, add extra per square, ·388.
Single-framed floor, with one girder, fixed per square - - 1·936
Strutting to be paid for extra.
Single-framed floor-case and tail-bays, fixed per square - - 2·130
For every extra bay, add per square, ·484.
Framed floors, with girders, binding and ceiling joists, fixed per square - - - - - - - - 3·581
Ground joists, bedded, fixed per square - - - ·775
Ground joists, framed to chimneys, fixed per square - - ·968
Ground joists, pinned down on plates and framed to chimneys, fixed per square - - - - - - - - 1·065
Girders reversed and bolted, per foot run - - - - ·097
Truss girder braces, 4 by 4, per foot run - - - - ·194
If any of the above works be executed in oak, add one third.

The following table is for roofing of various sorts: —

Common shed roofing, one story high, fixed per square - - ·968
Common shed roofing, two stories high, fixed per square - - 1·033
Common shed roofing, three stories high, fixed per square - - 1·113
Single span roofing, one story high, fixed per square - - 1·065
Single span roofing, two stories high, fixed per square - - 1·113
Single span roofing, three stories high, fixed per square - - 1·210
If the above are with purlins, add ·194 per square.
If purlins are framed diagonally, add ·388 per square.
Hips and valleys, per foot run - - - - - ·08
In common kerb roofing, add extra per square, when one side is kerbed - - - - - - ·194
When three sides - - - - - - ·357
When four sides - - - - - - ·516
Girt of roofing, with framed principals, collar beams, and purlins, fixed per square - - - - - - 2·323
Framed with principals, beams, king-posts, purlins, and common rafters, fixed per square - - - - - 3·484
If the principals and rafters are framed flush, and the purlins housed in, add ·387 day to the above.
Framed with principals, beams, king-posts, queen-posts, and common rafters, three stories, fixed per square - - - - 4·549 days.
The same, four stories, fixed per square - - - - 4·84
Hips and valleys, per foot run - - - - - ·145
Hip and ridge rolls, fixed in iron, per foot run - - - ·048
Bedded plates to common span roofing, per foot run - - ·008
Bedded plates to framed roofing, as above, per foot run - ·028
Diagonal and dragon pieces, per foot run - - - - ·065
Angular ties and struts, per foot run - - - - ·032
Rafters' feet and eaves bond, per foot run - - - - ·032

The table for guttering is as follows: —

Inch or inch and quarter deal and bearers, including 6-inch layer board, per foot super. - - - - - - ·057
The same in kerb roofs, per foot super. - - - - ·073

For furrings and battenings, table as follows: —

If the stuff be ¾ by 1½ inch, fixed per square	·872 day
If it has also to be cut out, add ·146 per square.	
Battenings with quarters, 3 by 2 inches, fixed per square	·92
Battenings to quarters, 3 by 2 inches to window piers, fixed per square	1·355
If the battens be fixed to plugs, add ·29 per square.	
When any of the above are circular on the plan, half as much more must be added to the price of the work.	

Table for bracketing, including plugging, is as under: —

To straight cornices, fixed per foot super.	·089 day
To coved straight cornices, fixed per foot super.	·065
If circular on the plan, add one half more.	
To groins in passages less than 4 feet wide, fixed per foot super.	·162
To the same above 4 feet, fixed per foot super.	·121

2351. The works of the JOINER consist in the preparation of boarding, which is measured and estimated by the foot superficial. Of this there are many varieties; as, edges shot; edges shot, ploughed, and tongued; wrought on one side and edges shot; the same on both sides and edges shot; wrought on both sides and ploughed and tongued. Boards keyed and clamped; mortice clamped, and mortice and mitre clamped. The value per foot increases according to the thickness of the stuff. When longitudinal joints are glued, an addition per foot is made; and if feather-tongued, still more.

2352. The measurement and estimation of floors is by the square, the price varying as the surface is wrought or plain; the method of connecting the longitudinal and heading joints, and also on the thickness of the stuff; as well as on the circumstance of the boards being laid one after another or folded; or whether laid with boards, battens, wainscot, or other wood. Skirtings are measured by the foot super., according to their position, as whether level, raking, or ramping. Also on the manner of finishing them, as whether plain, torus, rebated, scribed to floors or steps, or whether straight or circular on the plan.

2353. The value of every species of framing must depend on the thickness of the stuff employed, whether it is plain or moulded; and if the latter, whether the mouldings be struck on the solid, or laid in; whether mitred or scribed, and upon the number of panels in a given height and breadth, and also on the form of the plan.

2354. Wainscotings, window-linings, as backs and elbows; door linings, such as jambs and sofites, with their framed grounds; back linings, partitions, doors, shutters, and the like, are all measured and valued by the foot super. The same mode is applied to sashes and their frames, either together or separately.

2355. Skylights, the prices whereof depend on their plans and elevations, are also measured by the foot super.

2356. The value of dado, which varies as the plan is straight or circular, or being level or inclined, is measured by the foot super.

2357. In the measurement of staircases, the risers, treads, carriages, and brackets are, after being classed together, measured by the foot super., and the string board is sometimes included. The value varies as the steps may be flyers or winders, or from the risers being mitred into the string board, the treads dovetailed for balusters and the nosings returned, or whether the bottom edges of the risers are tongued into the step. The curtail step is valued by itself, and returned nosings are sometimes valued at the piece; and if they are circular on the plan, they are charged at double the price of straight ones. The handrail, whose value depends upon the materials and diameter of the well hole, or whether ramped, swan-necked, level, circular, or wreathed; whether got out of the solid, or in thicknesses glued up together, is measured by the foot run. The scroll is charged by itself, as is the making and fixing each joint screw, and 3 inches of the straight part at each end of the wreath is measured in. The deal balusters, as also the iron ones and the iron columns to curtail, housings to steps and risers, common cut brackets, square and circular on the plan, together with the preparing and fixing, are valued all by the piece. Extra sinking in the rail for iron balusters is valued by the foot run, the price depending on the rail as being straight, circular, wreathed, or ramped. The string board is measured by the foot super., and its value is greater or less as it is moulded, straight, or wreathed, or according to the method in which the wreathed string is constructed by being properly backed upon a cylinder.

2358. The shafts of columns are measured by the foot super., their value depending upon the diameter, or whether it be straight or curved on the side, and upon its being properly glued and blocked. If the columns be fluted, the flutes are taken in linear measure, the price depending on the size of the flutes, whose headings at top and bottom are charged by the piece. Pilasters, straight or curved in the height, are similarly measured, and the price taken by the foot super. In the caps and bases of pilasters, besides the mouldings, the mitres are charged so much each, according to the size.

2359. Mouldings, as in double-face architraves, base and surbase, or straight ones struck by the hand, are valued by the foot super. Base, surbase, and straight mouldings wrought by hand, are generally fixed at the same rate per foot, being something more than double-faced architraves. When the head of an architrave stands in a circular wall, its value is four times that of the perpendicular parts, as well on account of the extra time required to fit it to the circular plan as of the greater difficulty in forming the mitres. So all horizontal mouldings on a circular plan are three or four times the value of those on a straight plan, the trouble being increased as the radius of the circle upon which they are formed diminishes. The housings of mouldings are valued by the piece. The value of mouldings much depends on the number of their quirks, for each whereof the price increases. It will also, of course, depend on the materials of which they are formed, on their running figure, and whether raking or curved.

2360. Among the articles which are to be measured by the lineal foot are beads, fillets, bead or ogee capping, square angle staffs, inch ogees, inch quirk ogee, ovolo and bead, astragals and reeds on doors or shutters, small reeds, each in reeded mouldings, struck by hand up to half an inch, single cornice or architrave, grooved space to let in reeds and grooves. And it must be observed, that in grooving, stops are paid extra; if wrought by hand, still more; and yet more if circular. Besides the foregoing, narrow grounds to skirting, the same rebated or framed to chimneys, are measured by the foot run. Rule joints, cantilevers, trusses, and cut brackets for shelves are charged by the piece.

2361. Water trunks are valued according to their size by the foot run, their hopper heads and shoes being valued by the piece. Moulded weather-caps and joints by the piece. Scaffolding, where extra, must be allowed for. Flooring boards are prepared according to their length, not so much each; the standard width is 9 inches; if they are wider, the rate is increased, each board listing at so much per list. Battens are prepared in the same way, but at a different rate.

2362. The following memoranda are useful in estimating: —

1 hundred (120) 12-feet-3-inch deals, 9 inches wide (each deal containing, therefore, 2 feet 3 inches cube), equal $5\frac{2}{3}$ loads of timber.

1 hundred (120) 12-feet-$2\frac{1}{2}$-inch deals, 9 inches wide (each deal containing, therefore, 1 foot 10 inches cube), equal $4\frac{1}{2}$ loads of timber.

1 hundred (120) 12-feet-$1\frac{1}{2}$-inch deals equal 1 reduced hundred.

1 load of $1\frac{1}{2}$-inch plank, or deals, is 400 feet superficial.

1 load of 2-inch plank, or deals, is 300 feet superficial.

And so on in proportion.

Twenty-four 10-feet boards, at a 5-inch guage, will finish one square.

Twenty 10-feet boards, at 6-inch guage, will finish one square.

Seventeen 10-feet boards, at a 7-inch guage, will finish one square.

Fifteen 10-feet boards, at an 8-inch guage, will finish one square.

Thirteen 10-feet boards, and 2 ft. 6 in. super, at a 9-inch guage, will finish one square.

Twelve 10-feet boards, and 2 ft. 6 in. super., at a 10-inch guage, will finish one square.

Twenty 12-feet boards, at a 5-inch guage, will finish one square.

Sixteen 12-feet boards, at a 6-inch guage, will finish one square.

Fourteen 12-feet boards, at a 7-inch guage, will finish one square.

Twelve 12-feet boards and 4 feet super., at an 8-inch guage, will finish one square.

Eleven 12-feet boards, and 1 foot super., at a 9-inch guage, will finish one square.

Ten 12-feet boards, and 1 foot super., at a 10-inch guage, will finish one square.

Battens are 6 inches wide.

Deals are 9 inches wide.

Planks are 11 inches wide.

Feather-edged deals are equal to $\frac{3}{4}$-inch yellow deals; if white, equal to slit deal.

A reduced deal is $1\frac{1}{2}$-inch think, 11 inches wide, and 12 feet long.

2363. It may here be useful to advert to the mode of reducing deals to the standard of what is called a reduced deal, which evidently contains 1 ft. 4 in. 6 parts cube; for 12 ft. × 11 in. × $1\frac{1}{2}$ in. = 1 : 4·46, or in decimals, 12 ft. × ·91666 ft. × ·125 ft. = 1·375 cube ft. nearly. Hence the divisor 1·375 will serve as a constant for reducing deals of different lengths and thicknesses. Thus let it be required to find how many reduced deals there are in one 14 feet long, 10 inches wide, and $2\frac{1}{2}$ inches thick. Here 14 ft. × ·8333 ft. (or 10 in.) × ·20833 (or $2\frac{1}{2}$ in.) = 2·43042 cube feet, and $\frac{2\cdot43042}{1\cdot375} = 1\cdot767$ reduced deal.

2364. The table which is now subjoined exhibits the prices of deals and parts thereof calculated from 30*l.* to 95*l.* per hundred, a range of value out of which it can rarely happen that examples will occur, though it has fallen within our own experience during the late war to see the price of deals at a very extraordinary height. This, however, is not likely to happen again. The elements on which it is based are —

First.	Price of deals, each being 12 feet long, three inches thick, 10 inches wide. Then from $\frac{30l.}{120}$ we have the prime cost of each deal	5·00
Second.	Profit on prime cost, 15 per cent. - - - -	0·75
Third.	Planing both sides and waste, the former a constant depending on the price of labour (say 5*s.* per day used in the table), and the latter a variable, increasing with the cost price of the material -	0·8333
	6*s.* 7*d.* as in the table for a 12 feet deal =	6·5833

In the third element a *constant* (the planing) being involved and a *variable* (the waste) increasing with the cost of the material, the latter was eliminated by experiment and found equal to ·4166 shilling for every 10*l.* upwards of the price per hundred of the deals.

The width of the running foot is 9 inches. For instance at 45*l.* per cent. the cost of a foot super. (=144 in.) = 1·25*s.* = 1*s.* 3*d.* and of a foot run ·9375 shilling = $11\frac{1}{2}d.$ $\therefore \frac{144 \times \cdot 9375}{1 \cdot 25 \quad 12}$ = 9 inches.

Price per hundred.	Thickness.	10 feet long each.	12 feet long each.	14 feet long each.	Per foot run.	Per foot super.	Price per hundred.	Thickness.	10 feet long each.	12 feet long each.	14 feet long each.	Per foot run.	Per foot super.

2365. The above table we cannot suppose will require explanation; but as we wish to be quite explicit, we will merely take one example for illustrating its use, premising, that if deals are at a price between, above, or below that stated in the first column, the rules of arithmetic must be applied for the intermediate prices. Suppose deals, then, to be at 45*l.* per hundred; an inspection of the table shows that the value of $1\frac{1}{2}$-inch deal is 8*d.* per foot super., or 6*d.* run; that a 12-foot deal 2 inches thick is worth 6*s.* $8\frac{1}{4}d.$; and that a foot run of 3-inch deal 11 inches wide, which is the standard width, is worth $11\frac{1}{4}d.$ The preceding table, which is applicable purely to joinery, is all that can be given in general terms as to the prices of work; for that which follows we are again indebted, partly to Mr. Peter Nicholson, and partly to our own industry. The information is not all that could be desired on the subject, nor, as we have before said, can constants of labour be easily obtained for every article in a building; but, as far as they go, they must be considered valuable, though they seem not to have met with the reception they deserved. The value of the labour is given as before, in parts and decimal parts of a man's labour in each description of work per diem, so that the factor to be applied to each is the rate per diem at which the journeyman is engaged. The first table subjoined is one for doors, and in the first article of it, by way of application, suppose the wages of the joiner be 5*s.* 6*d.* per diem, that $=5{\cdot}5$ shillings will be the factor, and the price, therefore, of the labour on a $1\frac{1}{4}$-inch door, both sides square, will be $5{\cdot}5 \times {\cdot}06 = {\cdot}330$ shillings, or nearly 4*d.* per foot, without fitting and hanging. If to this be added the price of the quantity of deal used in it, from the foregoing table, we shall arrive at a result not far from its value. We proceed, then, in giving the constants of doors according to their most common descriptions.

Doors, $1\frac{1}{4}$ Inch thick.

2-panel, both sides square	per foot super. ·06
4-panel, both sides square	·07
6-panel, both sides square	·08
2-panel, quirk ovolo and bead, and square back	·1
4-panel, quirk ovolo and bead, and square back	·11
6-panel, quirk ovolo and bead, and square back	·12
2-panel, bead and flush front, and square back	·1
4-panel, bead and flush front, and square back	·11
6-panel, bead and flush front, and square back	·12
2-panel, bead and butt front, and square back	·09
4-panel, bead and butt front, and square back	·1
6-panel, bead and butt front, and square back	·11
2-panel, quirk ovolo and bead on both sides	·14
4-panel, quirk ovolo and bead on both sides	·15
6-panel, quirk ovolo and bead on both sides	·16
2-panel, bead and butt on both sides	·12
4-panel, bead and butt on both ends	·13
6-panel, bead and butt on both ends	·14
2-panel, bead and flush on both sides	·14
4-panel, bead and flush on both sides	·15
6-panel, bead and flush on both sides	·16

2366. In applying the above table to other thicknesses, for every additional thickness of one quarter of an inch the rate per foot super. must be increased ·005.

2367. When the panels are raised on one side, ·002 must be added, and double that (·004) when raised on both sides. If an astragal or ovolo is on one of the rising sides, ·003 must be added, and double that (·006) if such occur on both sides. Generally, if the number of panels be given, and the price per foot square on one side, with extra work on the other side, its price is one of the same number of panels, and the same number of panels on both sides minus the rate of the first from that of the last. But adding the difference of the second, we have the rate extra on both sides. Thus the rate is ·06 for $1\frac{1}{4}$-inch two-panel door, square on both sides, and for a two-panel door, square on one side, with quirk ovolo and bead upon the other, it is ·1. The difference is ·04, which added to ·1 = ·15 for the rate of $1\frac{1}{4}$-inch two-panel door, with ovolo and bead on both sides.

2368. We now turn to another of the items to be considered in measuring and estimating works, that of linings, wherein the difference of labour between square-framed door linings, backs, elbows, sofites, or wainscotings, and door square on both sides, where the panels and thicknesses are alike, arises only from planing the panels and the framing on the other side of the door. If the difference, therefore, per foot, on the rate of a door square on both sides, and one square on one side, with any extra work on the other side, be added to the rate of door-linings, backs, elbows, sofites, or wainscoting framed square, we shall have the rate per foot for door-linings, window-linings, or wainscoting, taking the extra work as above considered. The rails and stiles are taken in the rates as not rebated, and

the framed linings for walls or apertures are supposed as made of stuff one quarter of an inch thinner than the doors. Linings are uusually about an inch thick, being stiffened by fixing to the wall; but this depends on the distance of the panel's recess from the framing, and on the depth of the moulding employed.

FRAMED INCH LININGS.

1-panel, square as in backs - - - - - - per foot super.	·051
3-panel, square as in backs, and elbows measured together -	·071
4-panel, square as in backs, and elbows and sofites - -	·061
3-panel, moulded as in backs, and elbows together - -	·087
4-panel ditto and sofites measured together -	·077
3-panel, quirk moulded as in backs, and elbows measured together - - - - - - - -	·095
4-panel, quirk moulded as in backs, and sofites measured together - - - - - - - -	·085

Semicircular moulded sofites in two panels seven times the straight. For each additional quarter of an inch add ·005 to the foot super.

N.B. In the above table the backs, elbows, and sofites, though numbered as of 3 and 4 panels, are only of one panel each, the number being collected.

INCH AND A QUARTER DOOR-LININGS, ONE PANEL HIGH.

Rebated - - - - - - - - - per foot super.	·051
Rebated and beaded - - - - - - - -	·058
Double rebated, not exceeding 7 inches wide - - - -	·067
Double rebated, not exceeding 7 inches wide, and one edge beaded	·071
Double rebated, not exceeding 7 inches wide, and both edges beaded	·075

If the plan be circular, the price increases as the diameter diminishes.

Semicircular heads straight on the plan are worth five times as much as straight.

SHUTTERS, two panels in height, either shutters or flaps, inch framed, uncut If mouldings are described, they are considered as to be laid in, but if stuck on the framing, add ·012 to the rate. Add ·016 to the rate for every extra panel, and ·012 for any extra height, and ·008 if they are quirk moulded.

Square - - - - - - - - - per foot super.	·071
Bead butt and square - - - - - - - -	·1
Bead flush and square - - - - - - - -	·111
Bead flush and bead butt - - - - - - -	·131

Two panels in height, inch and quarter, uncut, adding for extras, as in the heading above.

Moulded and square - - - - - - - - per foot super.	·1
Moulded bead butt - - - - - - - -	·111
Moulded bead and flush - - - - - - -	·135
Moulded on both sides - - - - - - - -	·111
Ovolo and bead, or quirk ogee front, and square back - -	·103
Ovolo and bead, or quirk ogee front, with bead and butt back -	·123

WAINSCOTING, 1¼-inch, two panels high, with square fascia, framed up to ceiling.

Square - - - - - - - - - - per foot super.	·039
Moulded - - - - - - - - - -	·055
Quirk moulded - - - - - - - - -	·063
Bead and butt - - - - - - - - -	·051
Bead and flush - - - - - - - - -	·059
Bead and flush, with three reeds - - - -	·075

Should either of these be framed with raised mouldings, add ·008 to the rate, or framed with more, ·006 is to be added for each additional panel in height.

WAINSCOTING, 1¼-inch dwarf, one panel high, including square skirting.

Square - - - - - - - - - - per foot super.	·047
Moulded - - - - - - - - - -	·063
Quirk moulded - - - - - - - - -	·071
Bead and butt - - - - - - - - -	·059
Bead and flush - - - - - - - - -	·067
Bead and flush, with three reeds - - - -	·083

If dwarf wainscoting be framed with two panels in height, add ·016 to the rate, as in full wainscoting. When raked to stairs, ·023 extra, and when with raised mouldings, ·007. All cappings are measured run, and the skirtings of stairs must be taken separately from their wainscoting.

THREE-QUARTER-INCH or SLIT DEAL, from the bench.

Edges shot	per foot super. ·00
Wrought on one side	·01
Wrought on one side, grooved, tongued, and beaded	·02
Wrought on two sides, and edges shot	·02
Wrought on two sides, grooved, tongued, and beaded	·04

When joints glued, add per foot ·004.

INCH AND QUARTER DEAL.

Wrought on one side, and edges shot	per foot super. ·02
Wrought on both sides, and edges shot	·032
Wrought on one side, and ploughed and tongued	·036
Wrought on two sides, ploughed, tongued, and beaded	·052

With glued joints, add ·004 to the rate.

INCH AND HALF DEAL.

Edges shot	per foot super. ·008
Ploughed and tongued	·024
Wrought on one side, with edges shot	·02
Wrought on both sides, with edges shot	·036
Wrought on both sides, ploughed and tongued	·052

With glued joints, add ·012 to the rate.

TWO-INCH DEAL, from the bench.

Edges shot	per foot super. ·02
Ploughed and tongued	·036
Wrought on one side	·028
Wrought on both sides	·044
Wrought on both sides, ploughed and tongued	·056

With glued joints, add 016 to the rate.

TWO-AND-HALF-INCH DEAL, from the bench.

Edges shot	per foot super. ·028
Ploughed and tongued	·048
Wrought on one side	·048
Wrought on both sides	·063
Wrought on both sides, ploughed and tongued	·083

With glued joints, add ·016 to the rate.

THREE-INCH DEAL.

Edges shot	per foot super. ·032
Ploughed and tongued	·056
Wrought on one side	·056
Wrought on both sides	·08
Wrought on both sides, ploughed and tongued	·103

With glued joints, add ·016 to the rate.

INCH BOARDING, one side planed.

Ploughed and tongued	per foot super. ·24
Glued joint	·03
Clamped	·056
Mortice clamped	·063
Laid with straight joint in floors	·02
Keyed dado	·044
Keyed in backs and elbows	·056
Wrought on both sides, ploughed and tongued	·036
Wrought on both sides, glued joint	·04
Groove-clamped flaps to shutters, in one height	·053
Clamped flaps to shutters, in two heights	·071
Inch mortice, clamped, outside shutters	·063
Ledged doors, with plain joint	·044
Ledged doors, ploughed, tongued, and beaded	·056

PREPARING FLOORING BOARDS, guaged to a width, and rebated to a thickness not more than 9 inches wide.

Inch deals, 10 feet long	for each board ·063
Inch deals, 12 feet long	·075

PREPARING FLOORING BOARDS.

Inch deals, 14 feet long	for each board	·087
Inch and quarter deals, 10 feet long		·071
Inch and quarter deals, 12 feet long		·083
Inch and quarter deals, 14 feet long		·1
Inch and quarter battens, 10 feet long		·044
Inch and quarter battens, 12 feet long		·056
Inch and quarter battens, 14 feet long		·075

MOULDINGS, from the bench.

Double-faced architraves	per foot super.	·111
Base and surbase		·127
When above 4 inches girt, struck by hand		·127

In a combination of mouldings, with more than two quirks, add ·016 for each.

INCH AND INCH AND QUARTER FRAMED GROUNDS TO DOORS, from the bench.

Both edges square	per foot sup.	·028
One edge square, and the other rebated and beaded		·032
Rebated on one edge, and beaded on both edges		·036

Framed to a circular plan with flat sweeps, the head to be thrice the rate of straight, but the smaller the sweep the greater the rate.

RUNNING ARTICLES.

Beads and fillets	per foot run	·004
Bead or ogee capping		·016
Inch ogee		·016
Inch quirked ogee, or ovolo and bead		·023
Square angle staff, rebated		·028
Angle staff, rebated and beaded		·048
Single cornice or architrave		·048
Small reeds in reeded mouldings, stuck by hand to $\frac{1}{2}$ an inch		·004
Reeds above $\frac{1}{2}$ an inch, stuck by hand, including grooved space		·008
Grooves in ornamental work		·004
Narrow ground to skirting		·011
Narrow ground to skirting, rebated or grooved		·016
Narrow ground, framed to chimneys		·032
Double-beaded chair rail		·023

Plugging is included in the above rates. Such of the articles as are circular on plan, to be double rate.

Legs, rails, and runners to dressers	per foot run	·055
Rule joints to shutters		·063

STAIRS, inch and quarter nailed steps, with carriages.

Flyers	per foot super. fixed	·08
Winders		·111
Flyers, moulded and glued, with close string board		·103
Winders, moulded and glued, with close string board		·135
Moulded planceer under steps		·04
Housings to flyers	each	·127
Housings to winders		·2
Common cut brackets to flyers		·143
Common cut brackets to winders		·286

Fancy brackets to be paid for extra, according to their value

HANDRAIL, 2 inches deep and $2\frac{1}{4}$ inches broad.

Deal, moulded	per foot run fixed	·111
Deal, moulded and ramped		·495
Deal, moulded, level, circular		·413
Deal, moulded, wreathed		1·2
Mahogany, moulded, straight		·263
Mahogany, moulded, ramped		·831
Mahogany, moulded, ramped, swan-necked		·927
Mahogany, moulded, level, circular		1·08
Mahogany, moulded, wreathed, from 12 in. and above		1·6
Mahogany, moulded, wreathed, under 12 in.		1·8
Mahogany, moulded, wreathed, not less than 12 in. opening		2·8
Mahogany, moulded, wreathed, under 12 in. opening		3·4

HANDRAIL.

Extra sinking to rail, for iron balusters	per foot run fixed	·032
Extra sinking to rail, in ramp or wreath		·1
Mahogany moulded cap, wrought by hand, each		·495
Mahogany moulded cap, turned and mitred, each		·4
Mahogany scroll, each		1·8
Making and fixing each joint with joint screw		·231
Making model and fixing iron balusters		2·095
Making model and fixing iron columns to curtail, each		2·142
Preparing and fixing deal bar balusters, each		·04
Preparing and fixing deal bar balusters, dovetailed to steps		·056

Every half rail is measured two-thirds of a whole one; and all rails are measured 3 inches beyond the springing of every wreath or circular part.

All cylinders used in rails, glued up in thicknesses, to be paid for extra.

The following have not been before computed: —

FRENCH CASEMENT FRAMES.

Plain solid frames, oak sunk sills, weathered and throated for 1½ inch French casements, quarters not exceeding 4 by 3	per foot super. fixed	·045
Ditto, for 2-inch French casements, quarters 4 by 4		·057
Deal-cased frames, oak sunk sills, with wainscot stiles and beads, for 2-inch French casements		·086
Circular head, measured square		·258
Circular circular head, curve ¼ inch to a foot		·727
If with mahogany stiles and beads, add on the wainscot		·021
If any of the above are for 2½-inch sashes or casements, add on the deal		·014
If any on the wainscot		·021
If any on the mahogany		·028
Extra grooves or beads, add	per foot run	·014

Circular on plan, flat sweep, once and a half the straight.

Quirk on plan, double.

SASHES AND FRAMES, fitted and hung.

Deal cased frames, oak sunk sills, 1½-inch ovolo sashes, single hung brass pulleys, best white lines, and iron weights	per foot super.	·086
Ditto, double hung		·100
Ditto, double hung, circular head, measured square		·257
Ditto, circular on plan, flat sweep		·143
Deal cased frames, oak sunk sills, 2-inch ovolo sashes, single hung, brass pulleys, best white lines, and iron weights		·100
Ditto, double hung		·107
Ditto, double hung, circular head, measured square		·272
Ditto, double hung, circular on plan, flat sweep		·157
Circular circular head, ¼ inch to the foot		·770
Deal cased frames, oak sunk sills, wainscot pulley pieces and beads, 1½-inch wainscot astragal sashes, brass axle pulleys, single hung with patent lines		·121
Ditto, double hung		·143
Deal cased frames, oak sunk sills, wainscoat pulley pieces and beads, 1½-inch wainscot astragal sashes, brass axle pulleys with patent lines, circular on plan, flat sweep		·17
Circular circular head, ¼ inch to the foot		·86
Deal cased frames, oak sunk sills, wainscot pulley pieces and beads, 2-inch wainscot astragal sashes, brass axle pulleys, double hung with patent lines		·143
Ditto, circular head, measured square		·342
Ditto, circular on plan, flat sweep		·214
Circular circular head, ¼ inch to the foot		·909
Deal cased frames, oak sunk sills, mahogany pulley pieces and beads, 1½-inch Spanish mahogany astragal sashes, brass pulleys and patent lines, single hung		·157
Ditto, double hung		·171
Ditto, circular head, measured square		·371
Ditto, circular on plan, flat sweep		·257
Circular circular head, ¼ inch to the foot		·98

Deal cased frames, oak sunk sills, mahogany pulley pieces and

SASHES AND FRAMES.

beads, 2-inch Spanish mahogany astragal sashes, brass pulleys and patent lines	per foot super.	·178
Ditto, circular head, measured square		·399
Ditto, circular on plan, flat sweep		·272
Deal cased frames, oak sunk sills, mahogany pulley pieces and beads, 2½-inch Spanish mahogany astragal sashes, brass axle pulleys and patent lines		·243
Ditto, circular on plan, flat sweep		·315
Circular circular head ¼ inch to the foot		1·123
If Honduras mahogany, deduct from the straight		·029
If Honduras mahogany, deduct from the circular		·043
If lamb's tongue, or other modern modelled bar, add on the astragal		·014

VENETIAN AND PALLADIAN SASHES AND FRAMES, fitted and hung.

Venetian deal cased frames, oak sunk sills, 1¼ inch ovolo sashes, brass pulleys, double hung with best flax line and iron weights,	per foot super.	·111
Ditto, with 2-inch sashes		·129
Ditto, circular on plan, flat sweep		·172
Palladian head, measured square		·286
Circular Palladian head, measured square		·866
Venetian deal cased frames, wainscot pulley pieces and beads, 1½-inch wainscot astragal sashes, brass pulleys and patent lines, double hung		·157
Ditto, with 2-inch sashes		·172
Ditto, circular on plan, flat sweep		·200
Ditto, Palladian head, measured square		·342
Circular Palladian head, measured square		·952
If any of the above are in 2½-inch wainscot, add on the 2-inch straight		·014
Ditto, on the circular		·028
Ditto, on the circular circular		·043
If in Spanish mahogany, add on similar article in straight wainscot		·043
Ditto, on the circular		·114
If lamb's tongue, add on the astragal		·007
When any of the above sashes are with a bevelled bar up to the rebate, add on the astragal		·014

FRENCH CASEMENTS, fitted and hung.

1¼-inch deal ovolo	per foot super.	·057
2-inch deal ovolo		·064
2¼-inch deal ovolo		·071
1½-inch wainscot		·078
2-inch wainscot		·086
2½-inch wainscot		·100
1½-inch Honduras mahogany		·086
2-inch Honduras mahogany		·100
2½-inch Honduras mahogany		·114
1½-inch Spanish mahogany		·100
2-inch Spanish mahogany		·114
2½-inch Spanish mahogany		·129
If with margin lights, add on the deal		·018
If with margin lights, add on the wainscot		·029
If with margin lights, add on the mahogany		·036
If in two heights, add		·021
If in two heights add, on the wainscot		·029
If in two heights, add on the mahogany		·043
Circular on the plan, flat sweep, once and a half the straight, and exceeding ½ inch to the foot, double.		
If astragal and hollow lamb's tongue, or other modern bar, add		·014
If with bevelled bars up to the rebate, add on the astragal and hollow		·007
Extra rebated edges, grooves, or beads, in deal	per foot run	·014
Extra rebated edges, grooves, or beads, in wainscot		·021
Extra rebated edges, grooves, or beads, in mahogany		·028

SKYLIGHTS, fixed.

1½-inch deal ovolo	per foot super.	·043

Skylights.

2-inch deal ovolo	per foot super.	·050
2-inch oak ovolo		·071
If astragal and ovolo, add		·007

Dado.

¾-inch deal, keyed	per foot super.	·043
1-inch deal keyed		·050
Raking and scribed to steps, add		·012
If ploughed and tongued, add		·007
If feather-tongued, add		·012
Circular on plan, flat sweep		·143
Circular on plan, quirk sweep		·229
If 1¼-inch deal, add on the straight		·007
If 1¼-inch deal, add on the circular		·014
Narrow dado grounds		·018
Narrow dado grounds, circular flat sweep		·043

2369. We have now enumerated the principal articles of joinery in use. If further information be sought, and the reader have not the means of tracing the value in the way by which the constants already given have been obtained, he may refer to some of the price books, whereof we consider Skyring's to be as well digested as any of those that are annually published.

2370. Slater. The work of the slater is measured and estimated by the square of 100 feet superficial. Of the different sorts of slate, and how much a given quantity of each will cover, we have already spoken in Chap. II. Sect. IX. (1798, *et seq.*) To measure slating, in addition to the nett measure of the work, 6 inches are allowed for all the eaves, and 4 inches by their length for hips; such allowance being made in the first-named case because the slates are there double, and in the latter case for the waste in cutting away the sides of the slates to fit. When rags or imperial slates are used an additional allowance of 9 inches is made for the eaves, because those slates run larger than the other sorts.

2371. Mason. Solid works, such as pilasters, cornices, coping, stringings, and other solid works, should be first measured to ascertain the cubic quantity of stone they contain as going from the *banker* to the building; and on this, work, as it may happen to be the plain work, sunk work, moulded or circular work, must be measured in superficial feet and separately valued. It is usual to allow a plain face to each joint, but no more than one should be taken to a 3-feet length. In staircases the flyers should be taken where splayed on the back, their full length and width by three fifths of the depth of the riser, to allow for waste in getting two of the steps from the same block of stone. The measurement for the winders seems to be most properly conducted by ascertaining the nett cubic contents of them, and then making the allowance for waste. Indeed this is a more proper and satisfactory mode for the flyers. The top of the treads are then taken on the superficies as plain work, and the fronts and ends of the risers as moulded work. In an open staircase, the under side of the flyers is measured as plain work; the under side of the winders as circular plain work; the rebates, cuttings out, pinnings in, &c., as they are found. Cylindrical work, such as of columns, after the cube quantity is ascertained, is measured as equal to plain work twice taken. In Portland dressings to chimneys, wherever edges appear, it is customary to add an inch to the dimensions for extra labour; to marble, ¾ of an inch; or to take the running dimensions of the edges.

2372. Paving slabs and stones under 2 inches thick are taken by superficial measure. Cornices are measured by obtaining their girt, and multiplying by their length for the quantity of moulded work in them.

2373. The following are a few constants of the chief articles of labour in mason's work, applicable, as before mentioned, in the carpenter's and joiner's works.

Plain work	per foot super.	·166
Plain work, rubbed to face		·18
Plain work, tooled		·208
Sunk work		·222
Moulded work		·278
Moulded work, stopped		·333
Gothic moulded work		·445
Gothic moulded work, stopped		·528
Gothic moulded work, circular		·556
Circular plain work		·264
Circular sunk plain work		·333
Circular moulded plain work		·361
Circular, plain moulded work, stopped		·416

2374. FOUNDER. The proper mode of estimating cast iron is by the ton or cwt. Moulds for the castings, when out of the common course, are charged extra. Very often, too, cast iron pipes and gutters are, according to their sizes, charged by the yard. (See 1754, *et seq.*)

2375. SMITH and IRONMONGER. Wrought iron for chimney bars, iron ties, screw bolts, balusters with straps, area gratings, handrails and balusters, hook-and-eye hinges, brackets for shelves, chains for posts, wrought iron columns with caps and bases, fancy iron railing, casements, shutterbars, and the like, are charged by the pound, at various prices, according to the nature of the work. In the ironmonger's department nails and brads are charged by the hundred, though sold by weight, seldom exceeding 900 to the 1000. Screws, which take their names from their length, are charged by the dozen. Cast, and also wrought butts and screws, cast and wrought back flaps, butts and screws, side or H hinges, with screws, by the pair. All sorts of bolts with screws, of which the round part of the bolt determines the length, by the inch. HL hinges and cross garnet hinges, by the pair. Other hinges and screws by the piece. Locks by the piece. Pulleys according to their diameters. On all ironmongery 20 per cent. is charged on the prime cost. (See 2253, *et seq.*)

2376. PLASTERER. The work of the plasterer is measured, generally, by the yard. The most usual way of measuring stucco partitions and walls is, to take the height from the upper edge of the ground to half way up the cornice, the extra price of the stucco making good for the deficiency of floated work under it. In ceilings and other work, the surface under the cornice is often taken, because there is no deficiency but in the setting, and that is compensated for by the labour in making good. Cornices are measured by the foot, and estimated according to the quantity of mouldings and enrichments they contain. Where there are more than four angles in a room, each extra one is charged at the price per foot run extra of the cornice. Stucco reveals are charged per foot run, and according to their width of 4 or 9 inches or more. Quirks, arrisses, and beads by the foot run, as are margins to raised panels, small plain mouldings, &c. In the case of enriched cornices and mouldings, and flowers to ceilings, they must be considered with reference to the size and quantity of ornament. For these, the papier maché ornaments, (see 2251.) which are much lighter, are coming now into very general use, and from the ease and security with which they are fixed, will, we have no doubt, within no very distant period, supersede all use of plaster ornaments. In subsection 2248 will be found some information useful in the investigation of the value of plasterers' work, and which might form the basis for a set of constants under that head. But we have not been able to obtain sufficient data for carrying them completely out; which, from the minor importance of this branch of building, is perhaps of no very great consequence.

2377. PLUMBER. The work of this artificer is charged by the cwt., to which is added the labour of laying the lead. Water pipes, rain-water pipes, and funnel pipes are charged by the foot, according to their diameter; so also are socket pipes for sinks, joints being separately paid for. Common lead pumps, with iron work, including bucket, sucker, &c., at so much each; the same with hydraulic and other pumps, according to their diameters. In the same manner are charged water-closets, basins, air traps, washers and plugs, spindle valves, stop-cocks, ball-cocks, &c. (See 2212, *et seq.*)

2378. GLAZIER. The work of the glazier is measured and estimated by the superficial foot, according to the quality of the glass used; it is always measured between the rebates. (See 2225, *et seq.*)

2379. PAINTER. In the measurement and estimation of painting, the superficial quantity is taken, allowing all edges, sinkings, and girths as they appear. When work is cut in on both edges it is taken by the foot run. The quantity of feet is reduced to yards, by which painting is charged for large quantities. In taking iron railing the two sides are measured as flat work; but if it be full of ornament, once and a half, or twice, is taken for each side. Sash frames are taken each, and sash squares by the dozen. On gilding we have already spoken in Sect. XII. (2267, *et seq.*) Cornices, reveals to windows and doors, strings, window sills, water trunks and gutters, handrails, newels, &c., are taken by the foot run. Many small articles by the piece. Plain and enriched cornices by the foot run, according to the quantity of work in them. Work done from a ladder is paid for extra. The price depends on the number of times over that the work is painted; and the labour is usually considered as one third of the price charged. Imitations of woods and marbles are also charged extra.

2380. PAPERHANGER. In common papers the price varies according to the colours or quantity of blocks used in printing the pattern. Embossed and other papers are of higher prices. These, as well as lining paper, are charged by the piece, containing 63 feet super. The hanging is charged separate, and borders, mouldings, &c. by the yard run. (See 2278.)

CHAP. IV.

MEDIUM OF EXPRESSION.

SECT. I.

DRAWING IN GENERAL.

2381. Under this section it is not our intention to enter into the refinements of the art, but merely to make the attempt of directing the student to the first principles of a faithful representation of ordinary and familiar objects, with all their imperfections; or, in other words, of transferring to a plane surface what the artist actually sees or conceives in his mind. This power is of vital importance to the architect, and without it he is unworthy the name.

2382. The usual mode of teaching drawing now in use is, as we conceive, among the most absurd and extravagant methods of imparting instruction that can be well conceived. The learner is usually first put to copying drawings or prints, on which he is occupied for a considerable time. Much more would he learn, and much more quickly, by following the course which the following lines will prescribe. *Outline* is the foundation of all drawing; the alphabet of graphic art. As soon as the student has attained the use of the pencil and the pen in drawing purely geometrical figures, he is prepared to receive the rudiments of perspective. As shown in the following section, the representations of all geometrical solids is dependent upon mechanical means; and these may, if it be desirable, be shadowed truly by the methods given in Sect. III.; but what is now called free-hand drawing is the matter for our present consideration.

2383. Outline, as we have stated above, is the foundation of all drawing, the alphabet of graphic art. Every representation of an object, or series of objects, however complicated, is in reality but a set of outlines composed of straight or curved lines. The knowledge, or rather the power of forming these lines, is essential to the student, and in the same manner that he was obliged to form pothooks and hangers before he proceeded to ellipses when he was taught to write, he should begin his study of free-hand drawing by practising himself in the production of straight lines, proceeding to segments, and then to curves of contrary flexure. It is a good plan to compare the copy with the pattern; and, inasmuch as all formal diagrams that are set as patterns should be perfect, it is desirable that the standards for straight lines, segments, and contrary flexures should be drawn by the teacher himself from rulers; these rulers can be subsequently applied to the copies, and are sometimes the only evidence upon which to make a mutinous pupil conscious of his errors. The student ought not to proceed to the elliptical and oval forms until the hand, first turning one way, can draw a tolerably correct circle; and then, turning in the other direction, can make another equally good. The next step will be to acquire the power of drawing spiral lines in one direction, and of repeating them in another; which will be followed by that of drawing lines either parallel or slowly approximating.

2383*a*. After this, the student is sufficiently advanced to attempt to repeat all these stages with copies of a size larger or less than the patterns; and he will be ready to learn the mechanical use of chalk. This branch of his tuition needs only such examples as the prints, which have been prepared for that purpose, of purely geometrical forms: in this stage the rudiments of shadow are implanted, and the use of the brush may be acquired.

2383*b*. The student will then be ready to learn the mode of obtaining local colour, and of blending his materials so as to obtain tints and shades of the different colours. The next steps would be to draw in chalk, in ink, or in colour, the simplest architectural ornaments, such as a chevron or an ovolo; and to proceed through a course of architectural foliage from prints. The result of such training is usually a confidence in the eye; and, what is sometimes highly important, a judgment so sound as to be able to reproduce any part of a subject that may have been destroyed.

2383*c*. Aptitude of the pupil must be a consideration, but in general a year of steady application may be sufficient so to imbue the mind with the grammar of architectural ornament, as to enable the hand to represent it; after which the student ought to be capable of inventing for himself. Indeed, it is only by such a course that originality in designing ornament can be obtained. The study of natural foliage, first as seen, and then as conventionalized, may be carried out at the same time.

2383*d*. It is very remarkable that all the inferences are false, which usually are derived from the assertion that he who can draw the human figure will be able to draw any other object that is submitted to him for representation. The few men who can *faultlessly* draw the human figure as they see it, may doubtlessly have eyes keen enough and hands true enough to repeat the minutest details so accurately that any comparison of a particular detail with the original shall be creditable to them; but these men have spent years in obtaining, besides delicacy of handling, that knowledge of anatomy which reminds them at every stroke of the pencil that such a muscle is in such a place, that here it overlaps another, that there it dies into a bone, and that consequently they have to mark the curves and angles which occur, for instance, six or seven times between the elbow and the wrist, and to determine how many can be omitted if the scale be less than that of life.

2384. The majority of men who can draw the figure tolerably well can draw nothing else equally correctly: for the reason that their attention has been given to the mechanism of the human form solely; the representation, by our best portrait-painters, of the accessories which they introduce into their pictures, especially of architectural details, is almost without an exception ludicrously inaccurate. Every person who has tried to apply his power of representing geometric forms to the task of copying in chalk from a mask, must be aware of the enormous facility which he acquires by previously studying the usual methods of expressing the totality of the eye, the ear, the nose, and the lips. In a similar manner, the artist who wishes to give the effect of a suite of mouldings, or of a carved ornament, requires to know previously all the parts which compose the work. In other words, some men can pretend to sketch distant rocks and yet miss the very features by which the outlines intimate the geological character.

2385. Such are the reasons which have for many years led to the conviction that the architect's course of drawing should leave the figure alone until he has made one or more studies from carving in each style of art that opportunity presents to him; this is affirmed to be the only method of obtaining a satisfactory appreciation of the minute characteristics which sometimes constitute the differences between styles; and the only method of making a royal road to the object, which some teachers pretend is the easiest, but is truly the most difficult, in art. Having acquired the power of accurate representation of ornament, which involves dexterity in the use of his materials, the student may commence his operations with the figure.

2386. The method proposed in the following pages is old, at least in principle, yet it has been of late years published as new in Paris, by M. Dupuis. ("*De l'Enseignement du Dessin sous le point de vue industriel*," 1836.) The principles of the work, however, are perhaps better expressed and arranged, in some respects, than we might have presented them to the reader: and we shall not, therefore, apologise for the free use we make of it, premising, however, that in respect to the whole figure and the application of the method to landscapes, what follows is not found in the work of M. Dupuis.

2387. Between the ancient mode of teaching the student (we will take the head, for instance, shown in *fig.* 809. as the first roughing of the leading lines of that which in *fig.* 812. has reached its completion) and the method practised by M. Dupuis, the only difference is this, that M. D., instead of letting the student form the rough outline at once from the finished bust, roughing out on paper the principal masses, provides a series of models roughly bossed out in their different stages, which he makes the student draw. The system is ingenious; but as the greatest artists have been made without the modification in question, we do not think it material; at all events, the principles are the same. M. Dupuis, for this purpose, has a series of sixteen models, the first of each four of the series are quite sufficient to show the old as well as his own practice. Thus, in *fig.* 809., the general mass of the oval of the head is given, in which it is seen that the profile is indicated by an obtuse angle, whose extreme point corresponds with the lower part of the nose, and the lines at one extremity terminate with the roots or commencement of the hair, and at the other with the lower jaw. The form of the rest of the head is the result of combining the most projecting points of it by curved lines, in short, of supposing a rough mass, out of which the sculptor might actually, in marble or other material, form the head.

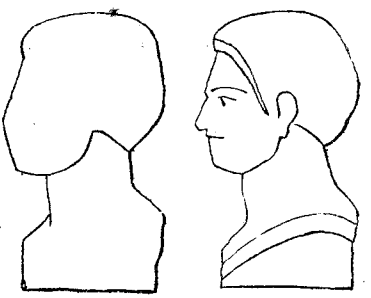

Fig. 809. Fig. 810.

2388. The next step is exhibited in *fig.* 810., with the four principal divisions: the occipital to the beginning of the hair, the forehead to the line of the eyes, the projection of the nose, and the inferior part of the face, with some indication of the mouth.

2389. In *fig.* 811. it will be seen that another step is gained. The eyes (here only one appears, but we speak with reference to the subject, being less in profile), the mouth, the chin, and the ear are more clearly marked out, with some sort of expression of the whole work, but still without details, though sufficiently indicating that little more is necessary to bring the rude sketch of *fig.* 809. to a resemblance.

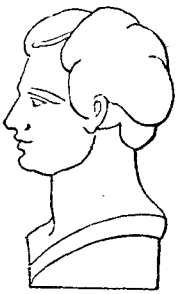

Fig. 811.

Fig. 812.

2390. In *fig.* 812. this is obtained; but still, according to the degree to which an artist considers finishing necessary, to be further pursued and carried through to make a perfect drawing; all that is here intended being to show the principles upon which the matter is conducted, and upon which we shall presently have further observations to make. It will be observed, that on the shadowing and finishing in this way the drawings the student may make we set no value: when he can draw, if those matters be of importance to him, they will not be difficult of acquisition.

2390*a*. Having accomplished the art of drawing, with tolerable correctness, the figure, the architect will have little difficulty in drawing the most complex productions of nature. The principles are precisely the same; but we wish here to impress upon him the necessity of recurring to nature herself for his ornaments: a practice which will always impart a freshness and novelty to them which even imitation of the antique will not impart.

2391. The port crayon, whether carrying chalk or a black lead pencil of moderate weight and size, say full seven inches long, is the best instrument to put into the hands of the beginner. The first object he must consider in roughing the subject, as in *fig.* 809., is the relation the height of the whole bears to its width; and this determined, he must proceed to get the general contour, without regard to any internal divisions, and thus proceed by subdivisions, bearing the relative proportions to each other of the model, comparing them with one another and with the whole. We will now show how the port crayon assists in this operation. Let the pupil be supposed seated before the model, at such a distance from it that at a single look, without changing the position of his head upwards, downwards, or sideways, his eye takes in the whole of it. The strictest attention to this point is necessary, for difficulties immediately present themselves if he is too near, as well as if he is too far from it. And here let it be observed that the visual rays (see *fig.* 813.) upon every object

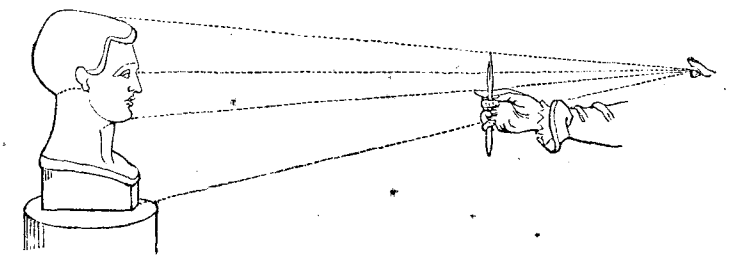

Fig. 813.

may be compared to the legs of a pair of compasses, which open wider as we approach the object and close as we recede from it. This is a law of perspective well known, and which the student may easily prove by experiment, keeping the head of the compasses near his eye, and opening the legs to take in, in looking along them, any dimension of an object. He will soon find that as he approaches such object he must open the legs wider in order to comprise within them the given dimension. Hence every diameter or dimension, separately considered, is comprised in the divergence of the visual rays. It is on this account that, being at a proper distance, any moveable measure which with a free motion of his body he can interpose upon some one of the points of the distance between his eye and the model, may, though much less than the model itself, take in the whole field of view, reach the extremities of the dimension, and consequently become of great assistance in certain mathematical measures. For by applying such a measure to one division only of the model, we shall obtain, as it were, an integer for finding a great many others into which the model may be subdivided.

2392. Thus, taking *fig.* 809., which is profile, and supposing the width at the neck unity, if this is twice and a half contained in the general height of the bust, we have immediately the proportions of one to two and a half, which may be immediately set out on the paper or canvas. This is not all; the integer or unity obtained by the diameter of the

neck serves also for measuring the horizontal diameter of the head. and also of the bust; whence new proportions may be obtained. So much for the first casting of the general form. Now, in the entire bust, as respects the head only, suppose we wish to obtain the proportions of the principal divisions, — for example, from the base of the bust to the base of the chin, — we may establish another integer to measure other parts; as, if from the point of view, the distance from the base of the bust to the base of the chin is the same as from the last to the summit of the head, the learner would have nothing more to do in that respect than to divide the whole height into two equal parts. On the same principle, passing from divisions to subdivisions, the distance between the base of the chin and the point whence the nose begins to project, may be found a measure for the height of the nose, and from thence to the top of the cranium. We are here merely showing the method of obtaining different integers for measuring the different parts mentioned; others will in practice occur continually, after a very little practice. We do not suppose our readers will believe that we propose to teach drawing by mathematical rules; we now only speak of obtaining points from which undulating and varying lines are to spring and return, and which none but a fine and sensitive eye will be able to express. But to return to the port crayon, which is the moveable measure or compasses whereto we have alluded, and requires only skilful handling to perform the offices of compasses, square, plumb rule, and level. By interposing it (see *fig.* 813.) on the divergence of the visual rays between the eye and the object, we may estimate the relative proportions; since in the field of view the learner may apply it to the whole or any of the parts, and make any one a measure for another. For this purpose he must hold it, as shown in the figure, steadily and at arm's length. Any portion of it that is cut by the visual rays between any two parts of the object, becomes the integer for the measurement of other parts whereof we have been speaking. This in the drawing will be increased according as the size is greater or less than the portion of the port crayon intercepting the visual rays. This process may be easily accomplished by making, upon one and the same line of the visual ray, the extreme point of the port crayon to touch one of the extremities of the proportion sought upon the model, so that they may exactly correspond. Then at the same time fixing the thumb or fore-finger where the visual ray from the other extremity is intercepted, we shall find any equal length by moving the port crayon with the thumb and fore-finger fixed to any other part we want, as to size, to compare with the first, or by using the same expedient to other parts, other integers may be found. The different integers, indeed, which may be thus obtained is infinite. The port crayon will also serve the purpose of a plumb bob by laying hold of it by the chalk, and holding it just only so tight between the fingers as to prevent its falling, so that its own gravity makes it assume a vertical direction. Doing so, if it then be held up to intercept the visual rays, we may discover the proportion in which a line swells whose direction approaches the vertical, as also the quantity one part projects before another in the model; and comparing this again with the integer, obtain new points for starting from. Again, by holding it before the eye in an horizontal direction, we shall obtain the different parts of the model that lie before the eye in the same horizontal line. By degrees we shall thus soon find the eye become familiarised with the model it contemplates; judgment in arranging the parts supervenes; the hand becomes bold and unhesitating, and the leading forms are quickly transferred to the paper or canvas to be subdivided to such extent as is required by the degree of finish intended to be bestowed upon the drawing.

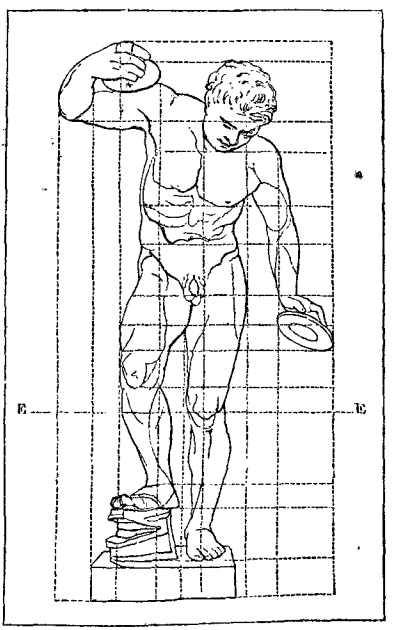

Fig. 814.

2393. The process that we have considered more with relation to the bust is equally applicable to the whole figure. In *fig.* 814. we have more particularly shown by the dotted lines the horizontal and vertical use of the port crayon; but the previous adjustment of some measure of unity for proportioning the great divisions to each other is also applied to it as already stated. In the figure, EE is the line of the horizon, or that level with the eye; it will be

seen passing through the knee of that leg upon which the principal weight of the body is thrown.

2394. Though our object in this section is to give only a notion of the way of transferring to paper or canvas such objects as present themselves, we think it proper to hint at a few general matters which the student will do well to consider, and these relate to the balance and motion of the human figure. Geometry and arithmetic were with the painters of antiquity of such importance that Pamphilus the master of Apelles declared, without them art could not be perfected. Vitruvius particularly tells us the same thing, and, as follows, gives the proportions of the human figure: — "From the chin to the top of the forehead, or to the roots of the hair, is a tenth part of the height of the whole body; from the chin to the crown of the head is an eighth part of the whole height; and from the nape of the neck to the crown of the head, the same. From the upper part of the breast to the roots of the hair, a sixth; to the crown of the head, a fourth. A third part of the height of the face is equal to that from the chin to the under side of the nostrils, and thence to the middle of the eyebrows the same: from the last to the roots of the hair, where the forehead ends, the remaining third part. The length of the foot is a sixth part of the height of the body; the fore-arm, a fourth part; the width of the breast a fourth part. Similarly," continues our author, "have the other members their due proportions, by attention to which the ancient painters and sculptors obtained so much reputation. Just so, the parts of temples should correspond with each other and with the whole. The navel is naturally placed in the centre of the human body; and if a man lie with his face upwards, and his hands and feet extended, and from his navel as the centre, a circle be described, it will touch his fingers and toes. It is not alone by a circle that the human body is thus circumscribed, as may be seen (*fig.* 815.) by placing it within a square. For, measuring from the feet to the crown of the head, and then across the arms fully extended, we find the latter measure equal to the former; so that the lines at right angles to each other, enclosing the figure, will form a square."

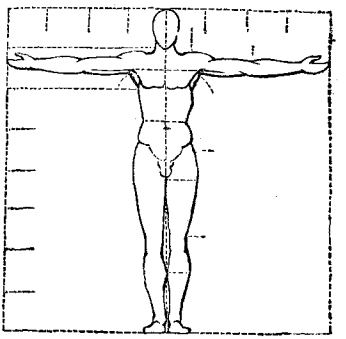

Fig. 815.

2395. "How well," says Flaxman (*Lectures on Sculpture*), "the ancients understood the balance of the figure, is proved by the two books of Archimedes on that subject; besides, it is impossible to see the numerous figures, springing, jumping, dancing, and falling, in the Herculaneum paintings, on the painted vases, and the antique basso-rilievos, without being assured that the painters and sculptors must have employed geometrical figures to determine the degrees of curvature in the body, and angular or rectilinear extent of the limbs, and to fix the centre of gravity." Leonardo da Vinci has illustrated the subject in his *Trattato di Pittura*, a perusal of which cannot fail of being highly beneficial to the student.

2396. As in all other bodies, the centre of gravity of the human figure is that point from which, if suspended, the figure would remain at rest when turned round upon it. Flaxman, by some strange mistake, has described the centre of gravity as "an imaginary straight *line*, which falls from the gullet between the ankles to the ground, when it (the figure) is perfectly upright, equally poised on both feet, with the hands hanging down on each side." (*Fig.* 816.). The fact is, that the centre of gravity is found to be in a line so drawn, or rather removed backwards from it, in a vertical plane returning from that line.

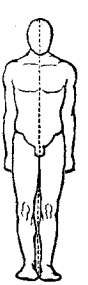

Fig. 816.

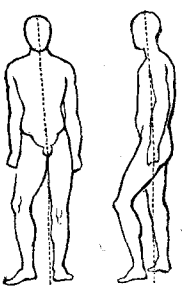

Fig. 817.

2397. Motion implies change of position; for instance, in *fig.* 817., the weight of the figure is thrown on one leg, hence a line passing through the centre of gravity falls from the gullet on one leg, on which side also the shoulder becomes lowered, and that on the opposite side raised; the hip and knee sinking below those on the side supporting the weight. In *fig.* 818. the dotted lines terminated by the letters ABCD represent lines of motion, as also the extent of such motion. The same are also shown in *fig.* 819., wherein A shows the inclination of the head to the breast; B the extreme bend of the back over the legs, without changing their position; C that of the back bent backwards, the legs

remaining in the same position. If the back be bent as far as D, the thighs and legs will project as far as E.

2398. Referring back to *fig.* 817. for comparison, as the commencement of motion, with *fig.* 820., we shall immediately see that the preparation for running consists in throwing the balance beyond the standing foot; and that when the centre of gravity, which is now about to take place, falls out of the common base, the hinder leg must be out, and off the ground, to balance the fore part of the figure, which would otherwise fall.

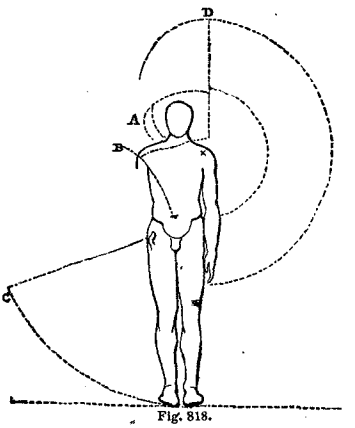

Fig. 818.

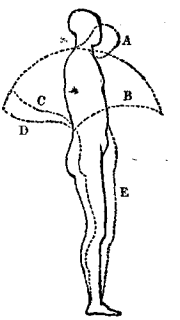

Fig. 819.

2399. In preparing to strike (*fig.* 821.), the figure is thrown back at the beginning of

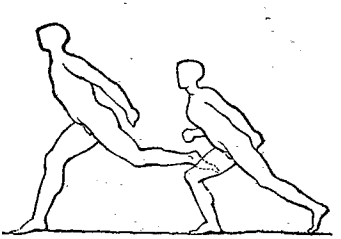

Fig. 820.

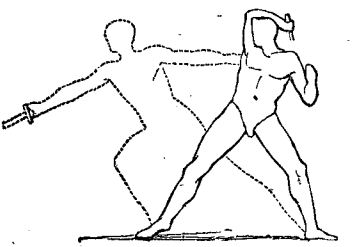

Fig. 821.

the action to give force to the blow: the dotted line shows the extent of the springing forward, in which the action is ended by the fall of the blow upon the object.

2400. In *fig.* 822., bearing a weight, the combined centres of gravity of the figure and

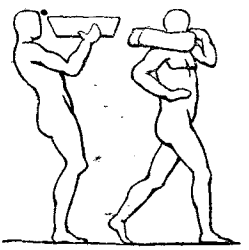

Fig. 822.

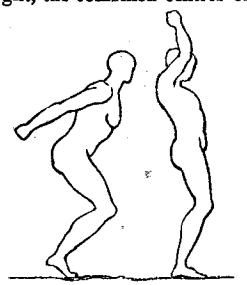

Fig. 823.

Fig. 824.

the weight to be borne must be found; and through it the line falls between the feet, if the whole weight rests equally on both, or on the supporting foot, if the weight is thrown upon one. Flaxman, who was a finer artist than a geometrician, has, in his lectures, fallen into another mistake on this head, by saying the centre of gravity is the centre of the incumbent weight, which is absurd; because the figure has not only to balance the weight itself, but also its own weight.

2401. In leaping (*fig.* 823.), the body and thighs are drawn together to prepare for the spring; the muscles of the leg draw up the heel, and the figure rests on the ball of the foot; the arms are thrown back to be ready immediately for swinging forward, and thus assisting in the impulse. When the figure alights, the arms, at the instant of alighting, will be found raised above the head; and a line dropped from the centre of gravity will be found to fall near the heels.

2402. In leaning (*fig.* 824.), if on more than one point, the greatest weight is about that point on which the figure chiefly rests.

2403. *Fig.* 825. is a flying, and *fig.* 826. a falling figure, both whereof being in motion through the air rest on no point. In the first it will be observed that the heaviest portion of the figure is bounded by lines inclined upwards; as in falling the heaviest portion of it has a downward direction We have thought these elements would be useful, as exhibiting those leading principles without the comprehension whereof no motion or action can be well expressed. "Every change," says Flaxman, "of position or action in the human figure will present the diligent student with some new application of principles, and some valuable example for his imitation."

Fig. 825. Fig. 826.

2404. We shall close this section with the application of the principles detailed in the management of the port crayon to the drawing of landscapes. The subject of *figs.* 827.

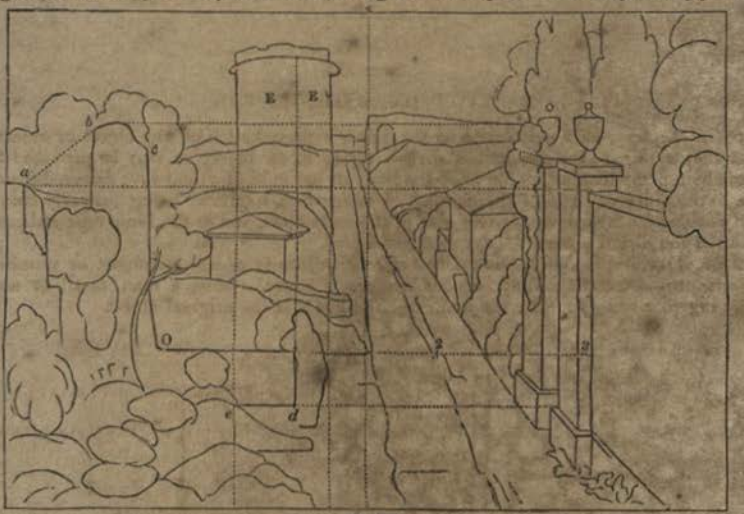

Fig. 827.

Fig. 828.

and 828. is from a spot a little way out of Rome, the tower of Cæcilia Metella being seen in the distance.

2404*a*. In *fig.* 826. the masses are roughed in from the objects themselves; and the principal mass *abc*0*ld* on the left side is first very carefully drawn by itself, being, as respects leading lines and thicknesses, corrected until the eye is satisfied of the truth of its general form. The eye is as high as E and E, which therefore show the height of the horizontal line, and are also, in fact, the vanishing points for the wall on the right-hand side of the picture, and the house on the same side a little beyond it. Holding the port crayon level, and taking on it with the thumb or forefinger the distance 01, we shall find that twice that measure in 2 and 3 will give the junction of the wall with the pier; and that a line continued horizontally from *d* cuts the top of the plinth of the gate pier. The picture happens to be divided into two equal parts by a vertical line drawn through the break in the city wall in the distance. *d*1, continued upwards, determines one side of the house on the right-hand side of the road, and from a point at a break in the foreground intersects the projecting wall at *e*; a vertical line determines the left side of the tower. The remaining horizontal lines, it will be seen, determine other points and lines; and thus it is manifest that the whole arrangement has been accomplished by making the mass *abc*0*ld* a measure or unit for ascertaining the size and relative position of the other parts. In *fig.* 828. the detail is filled in, and brought to a higher state of finish.

2404*b*. There is a mechanical method of obtaining the exact relative sizes of objects, and their positions in making drawings from nature or casts, which we will endeavour to explain. If the draftsman take a pair of pretty large sized compasses, and, fastening a piece of string at the joint end of them, hold the points open before his eye, so as to take in the extent of space his drawing is intended to occupy; then tie a knot in the string to keep it between his teeth, so that the compasses points may be kept in any plane always equally distant from the eye; he may, for the various parts of his drawing, by opening or closing the compasses, have their exact relative heights, widths, and positions, to be at once transferred to the drawing.

SECT. II.

PERSPECTIVE.

2405. A perspective delineation is the linear representation of any object or objects, as it or they appear to the eye, and is such a figure of an object as may be supposed to be made by a plane making a section of the body or pyramid of visual rays directed from the eye to the different parts of the object. A delineation so made, being properly coloured and shadowed, will convey a lively idea of the real object, and at the same time indicate its position and distance from the eye of the observer.

2406. DEFINITIONS. — 1. *An original object* or *objects* is or are an object or number of objects proposed to be delineated: for instance, a house, a ship, a man, or all or any of them together. In *fig.* 829. the house ABCDFHK is the original object.

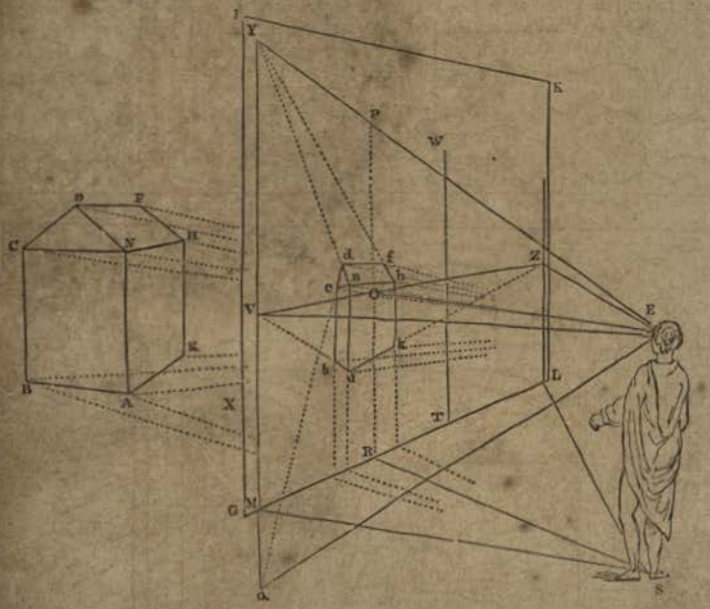

Fig. 829.

2. *Original lines* are any lines that are the boundaries of original objects, or of planes in those objects. The lines AB, BC, CD are original lines, being partly the boundaries of the original object ABCDFHK.

3. The *ground plane* is that upon which the objects to be drawn are placed, and is

always considered a boundless level plane. The plane X in the figure is the ground plane, upon which is placed the object ABCDFHK.

4. *The point of view* or *point of sight* is the fixed place of the eye of the observer, viewing the object or objects to be delineated: E in the figure is such point.
5. *The station point* is a point on the ground plane, perpendicularly under the point of sight or eye of the observer, and expresses on the plan the station whence the view is taken. S is the station point in the figure, being a point on the ground plane vertically under the eye of the observer at E.
6. *The plane of delineation* or *the picture* is the canvas or paper whereon it is intended to draw any object or number of objects. Thus, in the figure, the plane GIKL is the plane of delineation; but, in the extensive sense of the word, the plane of delineation is considered a boundless plane, however circumscribed may be the delineation made thereon.
7. *The horizontal line* or *the horizon* is a line on the plane of delineation in every part level with the eye of the observer or point of view. VZ is the horizontal line on the plane of delineation GIKL. It is supposed to be obtained by the intersection of a plane passing through the eye of the observer, parallel to the ground plane, produced till it touches the plane of delineation.
8. *The centre of the picture* is a point perpendicularly opposite the eye of the observer, or point of view, and is consequently always somewhere in the horizontal line. O in the horizontal line VZ is the centre of the picture, being perpendicularly opposite to the eye at E.
9. *The vertical line* is a line drawn through the centre of the picture perpendicular to the horizon. In the figure PR is the vertical line. It is here worthy of notice that the vertical line determines how much of the view lies to the right and how much to the left of the eye of the artist.
10. *The distance of the picture* is a direct line from the eye to the centre of the picture. EO is the distance of the picture, or plane of delineation, GIKL.
11. *The ground line* is that where the ground plane intersects the plane of delineation, as GL in the figure.
12. *An intersecting point* is one made on the plane of delineation, by producing a line in an original object till it touches the plane of delineation. Thus, T is the intersecting point of the original line BA.
13. *An intersecting line* is one made on the plane of delineation, by producing any plane in an original object till it touches the plane of delineation, or where, if produced, it would touch it. Thus WT is the intersecting line of the original plane ABCDN, being the line, where that plane, if produced, would touch the plane of delineation.
14. *A vanishing point* is that point on the plane of delineation to which two or more lines will converge, when they are the perspective representations of two or more parallel lines in an original object, whose seat is inclined to the plane of delineation. The point V in the figure is the vanishing point of the line AB, being found by the line EV, drawn from the eye of the spectator parallel to it, and produced till it touches the plane of delineation in the point V. For a similar reason, V is the vanishing point of the line CN; it is also the vanishing point for any other line parallel to the line CN, as BA; all parallel lines having the same vanishing point. The point Z is the vanishing point of the line AK, being obtained by a line drawn from the eye parallel to the line AK, and produced till it touches the plane of delineation. The point Z, moreover, is the vanishing point of the original lines DF and NH. And it is to be recollected by the student, that there will be as many different vanishing points of lines in the delineation of an original object as there are different directions of lines in that original object. The point Y is the vanishing point of the parallel original lines DN and FH, being found by the line EY being drawn from the eye parallel to them till it touches the plane of delineation. So also Q is the vanishing point of the line CD. In the process of perspective delineations, as we shall presently see, the plan of the object being drawn, the places of the various vanishing points are found on the ground line, whence they are transferred to the horizontal line by means of perpendiculars raised from them.
15. *A vanishing line* is one supposed to be made on the picture by a plane passing through the eye of the observer parallel to any original plane produced till it touches the picture. The line VZ is the vanishing line of an horizontal plane, and of all horizontal planes, being found by the intersection of a plane passing horizontally through the eye, or parallel to an horizontal plane. The vertical line YVM is the vanishing line of the original vertical plane, ABCDN being the line where a plane passing the eye of the spectator parallel to that plane would touch the plane of delineation. There will be as many different vanishing lines on the plane of delineation as there are different positions of planes in the object or objects; and

all parallel planes will have the same vanishing line. Similarly, all lines lying in the same plane will have their vanishing points in the vanishing line of that plane. All planes or lines in an original object which are situated parallel to the plane of delineation can have no vanishing lines or vanishing points on the plane of delineation.

16. *A visual ray* is an imaginary right line, drawn from the eye to any point of observation. EA and EY, &c. are visual rays, being right lines drawn from the eye to the points A and Y. Hence a number of visual rays directed to every part of an object will form a pyramid of rays, whereof the eye is the apex, and the object the base.

17. *A perspective delineation*, then, is the section of a pyramid of rays producing a perspective projection, and is most commonly considered as being made between the object and the eye. But the section of rays may be taken when they are extended beyond the object; in which case such a section is called a *projected* perspective representation of the object.

2407. It will then be seen that a knowledge of perspective is, as Addison has said, a knowledge of "the science by which things are ranged in picture, according to their appearance in their real situation."

2408. The situation of the objects being given with the plan and position of the plane of delineation and the height and distance of the eye of the observer, the delineation of such objects is truly determinable by rule. The mechanical operations necessary for this purpose form the subject of what follows. It is however necessary, before proceeding to lay them before the reader, to premise that he must thoroughly study and understand the preceding definitions before he can proceed with profit to himself, and we recommend a repeated perusal of them until that be effectually accomplished.

2409. Example I. In *fig.* 830., No. 1., we have the plan of the original object

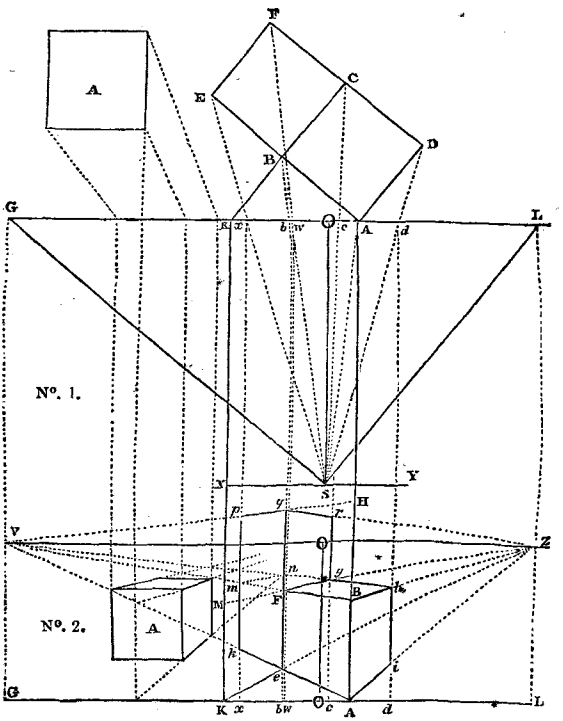

Fig. 830.

EBADCF, whereof ABCD is a cube, and BCEF a double cube, that is, twice the height of CBAD. GL is the plan of the ground line; S, the station point. Through S draw XY parallel to the plane of delineation GL, and draw SG and SL respectively parallel to the sides EA and AD of the united cubes ABCD and BCFE; and these produced to meet

the plane of delineation will determine the vanishing points (Def. 14.) of the horizontal lines AE and AD, and of all other horizontal lines parallel to them. Draw the line SO perpendicular to GL, which line being the direction of the eye perpendicular to the plane of the picture determines the point thereon to which the eye should be directly opposite to view it when completed, showing also how much of the object is on one side, and how much on the other of the point of view. We have now to draw the visual rays SA, SB, SE, SF, SC, SD, cutting the plane of the picture or delineation in *b*, *x*, *w*, *c*, and *d*; the point A of the nearest cube touching, itself, the picture at that point. The preparation on the plan is now completed.

2410. The picture (No. 2.) or plane of delineation is to be prepared as follows: — First draw the ground line GL, and to such ground line transfer, by dropping verticals, the points K*xbwc*A and *d*. Above, and parallel to GL, at such convenient height as may be necessary to show more or less of the upper surfaces of the cubes or otherwise, as desired, draw the horizontal line VZ; mark on such horizontal line the point O, to which the eye is supposed to be perpendicularly opposite for viewing the delineation when completed. All the other preparations are obtained from the plan, and may be obtained as follows: — First set off on the horizontal line VZ the points V and Z, which are the vanishing points of the sides AE and AD respectively. As A, the nearest angle of the object, touches the plane of delineation, it is manifest that a line vertically drawn from that point will be of the same height as the object itself, that is, as the figures are cubes, equal to AB or AD in the plan No. 1. Take, therefore, AB No. 2. of the height required, and draw the lines BV and AV, also AZ and BZ, which being crossed by verticals carried up from *xbwcd* will determine the points *ke* and *i* at the bottom, and in *f* and *h* at the top, and *pq* and *r* in the part where the cube is double the height. Drawing *h*V it is intersected by the verticals from the visual rays at *c* and *w*, cutting in *g* and *n*. The line KK forms another line of heights, if desired, for finding the height F*q*; indeed, by continuing any line BC (No. 1.) to K, intersecting the picture, a line of height may be obtained. The representation of the cube marked A will be understood without difficulty, if what has preceded be well comprehended. As by Definition 15. we have seen that all planes or lines in an original object situated parallel to the plane of delineation have no vanishing lines or points in the plane of delineation, so two of the sides of the cube will be bounded by horizontal and vertical lines, inasmuch as those sides lie parallel to the plane of delineation. The vanishing points for the other lines will of course be found in O, which passes through the picture at right angles to it from S, the station point.

2411. Example II. To find the representation of a quadrangular building, situated inclined to the picture, covered with a single spanned roof, having a gable at each end.

2412. Let the rectangle ABCD (No. 4.) (*fig.* 831.) be the plan of the building, the line EF will be the place of the ridge of the roof extending from end to end. Let the line QL be the place of the plane of delineation, and let S be the station point.

2413. Find O the centre of the picture, also the points Q and L, the vanishing points of the lines AB and AD, and their parallels, by lines drawn from S parallel to such lines, and intersecting the picture. Produce the face of the building AD to I for an intersection with the picture, and draw the visual rays intersecting the ground line of the picture in the points *beaf* and *d*. These need not, however, be drawn beyond the plane of delineation.

2414. Prepare the picture (No. 5.) by drawing the horizontal and ground lines VZ and GR at any distance from each other at pleasure; fix upon the centre of the picture O, and draw the vertical line OO; set off the distances of the vanishing points OV and OZ, equal the distances o the vanishing points OQ and OL in No. 4. Draw the intersecting line IL (No. 5.), and all the visual lines, through the points *beaf* and *d*, taken from their respective places and distances *beaf* and *d* (No. 4.), and proceed as follows: —

2415. On the intersecting line IL (No. 5.) set up the height IK equal to the height of the building BC or HG (Nos. 1. and 2.), and draw the lines KZ and IZ, determining the plane *gmop* for the front of the building. Draw the lines *m*V and *g*V, determining the end of the building *ghim*. It now remains to place the roof, which is readily done, but which, however, requires some circumspection in the process.

2416. Place the height of the roof XD (No. 1.) on the intersecting line at IL (No. 5.), and draw LZ, which will give the height of the roof on the angular line of the building *gm* at *r*; from which spot it may readily be transferred to its proper place in the visual line *ek* by the line *r*V, which cuts the line *ek* in the point *k*, the point required. From the point *k* draw the lines *ki* and *km*, completing the gable end of the building. Draw the ridge of the roof *k*Z, cutting the end visual line, in the point *n*; and lastly, draw the line *no*, completing the whole linear delineation of the building *ghiknop*. It is to be observed, that whatever original plane is produced to the picture to obtain an intersection, such intersection serves only to obtain heights in the direction of that plane; whence they may be transferred to other planes in contact with it, as in the present instance. The intersecting line IL (No 5.) is the intersecting line of the plane *gmop*; hence any original height set up

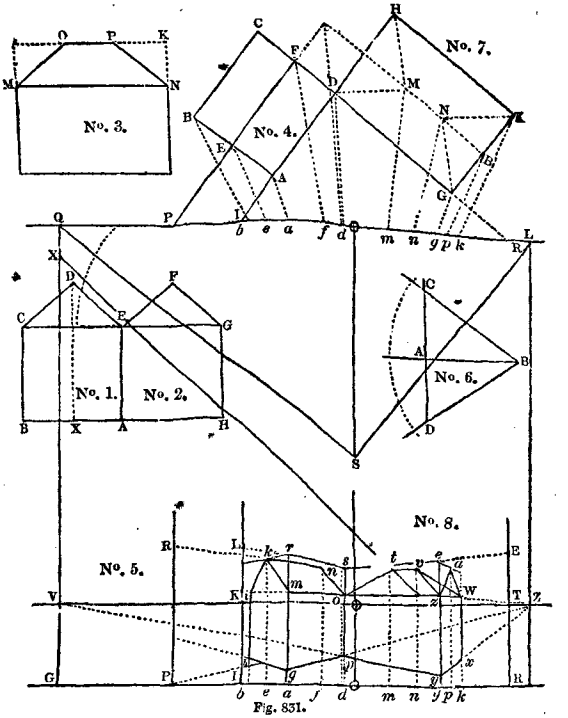

Fig. 831.

thereon can only be transferred throughout the direction of that plane. Thus the height of the roof IL was transferred by the line LZ along that plane to its other extremity *s*; but the line *rs* is not the place of the ridge of the roof, which lies in the middle of the plane *ghikm*, proceeding from the point *k*; but any height on the angular line *gr* is easily transferred along that plane by means of its horizontal vanishing point V, by which means the height of the roof was obtained by the line *r*V at *k*. If, instead of the plane over the line AD (No. 4.) being produced for an intersection, the plane of the middle of the house in the direction of the ridge of the roof had been drawn, and the height of the roof had been set up on that line, it would at one application be transferred to its proper place.

2417. Let the line FE (No. 4.) be produced to P for an intersection, set off the distance OP at OP (No. 5.), and draw the intersecting line PR. On PR set up the height of the ridge of the roof equal XD (No. 1.), and draw the ridge line RZ, and it determines the exact ridge of the roof between the proper visual lines, and will be found to correspond exactly with the ridge obtained by the former process.

2418. The roof may, however, be found by another process, thus:—The slant lines of the roof have their vanishing points on the picture as well as any other direction of lines in the same object. The line *km* (No. 5.) being in the vertical plane *ghikm*, will have its vanishing points somewhere in the vanishing line of that plane. (Def. 15.) A vertical line drawn through the horizontal vanishing point V will be the vanishing line of the plane *ghikm*; therefore the vanishing point of the lines *km*, *ki*, and of all lines parallel to them, will be somewhere in the vertical GVXQ.

2419. Two lines drawn from the eye parallel to any two lines in an object, finding their vanishing points, will make the same angle at the eye as the lines in the object make with each other; for the two lines in the one instance are respectively parallel to the two lines in the other.

2420. The line SQ is drawn from the station S parallel to the line AB (No. 4.), and a line drawn from the station S, making the same angle with SQ as ED does with EC, (No. 1.), will find the vanishing point of the line ED, and this point must be evidently somewhere in a vertical line through the point Q. To obtain this point in practice, take the distance of the vanishing line it is in, that is, the length from S to Q in the compasses, and set off the same in the horizon (No. 5.) from V. to W. At the point W make an angle VWX equal to the inclination of the roof, that is, equal to the angle CED (No. 1.), and

produce the line till it intersects the vertical line through the vanishing point V in the horizon in the point X. The point X will be the vanishing point of the line of the roof *km* (No. 5.), and of the line *no*, parallel to it. The slant lines of the roof *km* and *no*, already obtained, will, on application of a ruler, be found to tend to the point X, as above stated.

2421. In the same way the line of the roof *ki* (No. 5.) will also have its vanishing point, and in the same vertical line GVQ. It will be found to be as much below the horizontal vanishing point V as the point X is above it. (Def. 14.)

2422. Let the line AB (No. 6.) be the line of the horizon, and CD the vanishing line of a vertical plane, being the gable end of a house, and let the angle ABC be that of inclination, finding the vanishing point of the slant lines of a roof in one direction. Let the line BD be the line, finding the vanishing point of the slant lines in the other direction, having the same inclination to an horizontal line; then the angle ABD will be equal to the angle ABC, and the distance AD equal to the distance AC.

2423. Example III. To find the representation of a quadrangular building situated inclined to the picture, covered with a single hipped roof.

2424. Let the quadrangle GDHK (No. 7.) be the plan of the building; the line MN will represent the ridge of the roof. The former line QL may be the place of the plane of delineation, and it may be viewed from the same station S. The position and direction of the lines of this object being the same as those of the last example, the preparatory lines will also answer for this. We have then only to draw the visual rays MS, NS, CS, PS, and KS, intersecting the picture in the points *m*, *n*, *g*, *p*, and *k*, and to produce the line DG for an intersecting point at R.

2425. Prepare the picture (No. 8.); let the line VZ be the horizon, GR the ground line, O the centre of the picture, and the points *m*, *n*, *g p*, and *k* coresponding with *m*, *n*, *g*, *p* and *k*. (No. 7.) Draw the visual line lines through those points and the intersecting point R, and proceed as follows: —

2426. On the intersecting line RE set up the height RT, equal the height of the object HG (No. 2.), and draw the lines TV and RV, cutting the visual lines of the front of the building in the points *z* and *o*, *y* and *p*, determining the plane *ypoz* for the representation of the plane of the front. From the angular points *z* and *y* draw the lines *zw* and *yx* to their vanishing point Z determining the plane *yzwx* for the end of the building.

2427. On the intersecting line set up the height of the roof TE equal the height NK (No. 3.), and draw EV cutting the angular visual line of the building in the point *e*, from which point draw the line *ez*, cutting the visual line *pa* in the point *a*, the point of direction of the ridge of the roof. Draw the line *a*V, which, cutting the visual lines through the points *m* and *n* in the points *t* and *v*, determines the exact position of the ridge of the roof *tv*, which is the representation of OP (No. 3.), or of the ridge MN (No. 7.); draw the lines *to*, *vz*, and *vw*, which will complete the whole representation required. In No. 8., if the lines *az* and *aw* be drawn, they will form a gable end *yzawx*, of which the point *a* is the point of the gable, and will answer for the direction of the ridge, whether it be a gable end or a nipped roof, for in both cases it lies in the middle of the breadth of the house; wherefore the line *a*V answers as well the edge of a hipped roof as of a gable end.

2428. In examining the plans (Nos. 4. and 7.) of the two buildings, it will be seen that they are placed at right angles to each other, and in contact at the point D, so that the second example might have been easily accomplished from the first, without the aid of another intersection and other preparatory lines, than the additional visual rays from the angles, which the student will have surely no difficulty in carrying through, without the necessity of encumbering these pages with the detail.

2429. Example IV. In *fig.* 832. No. 1. is the general plan of a church similar to many country churches. ABCD is the main body of it; EFGH its tower; IKLM and MLNO subordinate parts of the building, and *abcd* the porch. No. 2. is its geometrical elevation; the ends and measurements, AB and BC, answering to IM and MO in No. 1., and the points of the roofs D, E, and F. (No. 2.) answering to the lines of the ridges QR, TV, and PL, No. 1. To find the perspective representation of this building on the plane of delineation YZ, the station being at S, the following is, perhaps, the readiest process.

2430. Find the vanishing points Y and Z of the horizontal lines of the building by the lines SY and SZ being drawn from the station parallel to them. O is the centre of the picture. Draw the visual rays from the visible angles of the object in direction to the station S, to intersect the plane of delineation.

2431. When a complicated object, that is, one composed of many parts, is to be drawn, it requires, of course, a great number of visual rays for the precise determination of those parts, and the whole together forms an apparently confused number of lines. The eye, however, which views them properly, does not perceive that confusion; and, if it perplex the student, different coloured inks, or of different shades of depth, may be used to particularise different parts. In the delineation of such an object as the present example, the most important consideration is the choice of a proper intersection; for though any inter-

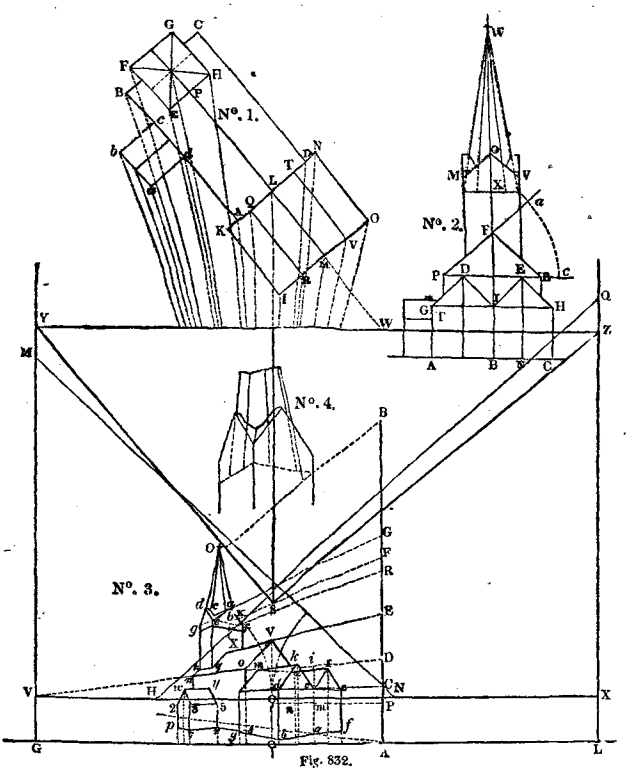

Fig. 832.

section will do, that should be chosen which unites most parts in its direction with the greatest exactness and the least trouble. In the case under consideration, none seems more eligible than the direction of the roof PLM, which produce to W.

2432. In the picture No. 3., GL is the ground line, GV the height of the horizon, the line VX being then the horizontal line. O in the horizon is then the centre of the picture, from which, place the distances of the horizontal vanishing points OV and OX equal OY and OZ, No. 1. AB (No. 3.) is the intersecting line, and all the visual lines on the plane of delineation are drawn conformably to their intersections on the ground line in the plan. On the intersecting line the height AC is made equal to the height AG of the elevation No. 2.; and the lines Cc and A*a*, being drawn in direction to the vanishing point V, determine the height *ac*; being the height of that part of the building on the visual line answering to the ray from the point M in the plan No. 1. Through the points *a* and *c* draw the lines *de* and *bf* to their vanishing point X, determining the plane *bdef*, the representation of the plane AGHC, No. 2.; the visual lines *bd* and *fe* answering to the rays from the points I and O in the plan. Draw the lines *dh* and *bg* tending to their vanishing point V, to the ray from K in the plan completing the plane *bghd*. On the intersection make the height AD equal to the height of the roof NE of the elevation No. 2., and draw D*i* in direction to V. Through *i* draw the line *kl* to the vanishing point X, touching the visual lines of the roofs in the points *k* and *l*. Draw the lines *km*, *mh*, *kd*, *kc*, *lc* and *le*, which will complete the whole of the structure over the plan IKNO, No. 1.

2433. The height of the roofs of the low buildings is equal to the height of the upright walls of the body of the building, as shown by the line PR in the elevation No. 2.; hence, the line *mo*, and the return line *on*, may be drawn to the visual lines corresponding with the intersections from the angles A and B of the plan From the angle *g* the line *gs* may also be drawn, which will determine the lines *sr*, *rt*, and *tp* of the porch. Make AE on the intersection equal to the height of the roof BF in the elevation, and draw the line EV determining the ridge of the roof between the two visual lines from the points P and L of the plan. Draw the lines of the gable end *vo* and *vz*, the point *z* being obtained by the line *om* drawn to its vanishing point X, cutting the visual line from the angle D of the plan in the point *z*.

2434. Make AG and AF on the intersection equal to the heights of the tower BO and BM of the elevation, and draw the lines GV and FV cutting the visual line from P in the plan, in the points *a* and *b*; through which points draw the lines *ac* and *ef* to their vanishing point X; and the lines *cd* and *eg* to their vanishing point V; the points *g*, *e*, and *f* being in the proper visual lines from the angles of the tower F, E, and H in the plan. The tower will be completed by drawing the lines *dg*, *de*, *ae*, and *af*.

2435. This example elucidates the general practice of vanishing points, which are as well to be obtained of other positions of lines as horizontal ones. It is not always that the vanishing points of inclined lines are required, but they are often useful, and sometimes absolutely necessary. In the geometrical elevation No 2. the lines MO, PF, GD, IE are all parallel lines, as also are the lines OV, FR, EH, and DI, and though situated in different, yet they are in parallel planes, and will therefore have a common vanishing point. A line drawn perpendicularly to the horizon through the vanishing point X (*fig.* 3.), as LQ, will be the vanishing line of the plane of the end of the church over the line IO of the plan, also of the end of the body AD, likewise of the side of the tower EH; and a line drawn through the point V (No. 3.) perpendicularly to the horizon, as GM, will be the vanishing line of the planes over the lines (No. 1.) IK, AB, *ab* of the porch, and FE of the tower, and all lines in those planes, or the boundaries of those planes, will have their vanishing points somewhere in those vanishing lines.

2436. To obtain the vanishing points of the inclined lines of the roofs and tower, take the distance of the vanishing point Z from the station S in the compasses, and apply it on the horizon from X to H. At the point H make an angle with the horizontal line equal the angle of the roofs *a*Pc (No. 2.); the curve KI and the distance of it from the centre H being equal to the curve *ac*, and distance of it from its centre P: then is the angle KHI equal to the angle of the roof *a*Pc (No. 2.). Produce the line HK to Q; Q will be the vanishing point of the line *ea* of the tower, also of the parallel lines *ov*, *dk*, and *cl*, which, though obtained by a different process, will all be found, by application of a ruler, to tend truly to that point, as is shown by the dotted lines in the example. Proceeding in the same way with the distance of the vanishing point Y from the station S, we obtain the vanishing point of the same inclination of lines in the other planes of the object. Take the length SY in the compasses, and set it off on the horizon from V to N. At the point N make an angle INT on the horizon equal the angle KHI, that is, equal the angle of inclination of the roof *a*Pc (No. 2.). The line NT produced to M in the vanishing line GM will be the vanishing point of the line *de* of the top of the tower, also of the lines *w3* and *y5* of the porch (the inclination of the roof of the porch being the same as the other roofs of the body of the church), as shown by the dotted lines in the example. The walls of the porch are obtained from the height AP on the intersection, equal the height AT, No. 2., P*m* being drawn to the vanishing point V, and *mn* to X, give the lines *n5*, *53*, and 32. We may observe that the inclined lines *af*, *le*, *kc*, and *vz* have a common vanishing point, which, if required, may be obtained; it will be in the same vanishing line with the point Q, and as much below the horizontal vanishing point X as the point Q is above it, to which point, were it obtained, the lines already drawn will be found exactly to tend. It is seldom absolutely necessary to have both those points; in this instance one only of them, the point Q, is obtained, which answers every end required of both; for, supposing it were left to that vanishing point for finding the inclined lines, the visual lines being drawn, and the heights of the upright walls being found, the line *dk* being drawn in direction to the vanishing point Q determines one side of the gable end at the visual line in the middle; the other is accomplished by joining the points *k* and *c* together. So of the other gable, *cl* being drawn, *le* is also had by joining together the points *l* and *e*.

2437. To complete the whole, draw the line *xq* on the tower from the point *x* to the angle of the tower, in direction to the vanishing point Q; then draw the lines *qh* and *nh* to their proper visual lines and vanishing points V and Q. The putting on of the spire requires some consideration, and in it we must proceed with some thought and care. The base of it is intended to be a regular octagon. If the two external lines in the geometrical elevation of the spire be continued till they touch the sides of the tower, as is done at K and L (No. 2.), and an octagon be there constructed, extending the square of the tower, it will be the base of the spire. Set up the height of the spire BW (No. 2.) on the intersection (No. 3.) at B; also the height of the base line KL at R, and draw the lines BV and RV; the first, cutting the visual line through the centre of the tower in the point O, determines the height of the spire; the other, cutting the tower in the point *u*, determines its base. Through the point *u* draw a line round the lower, and find the points of the octagon in the middle of each face of the tower, to which let lines be drawn from the top O, and the whole will be completed, as shown in the example.

2438. Thus have we gone through the process of finding the representation of rather a complicated object with as little confusion of lines as possible; but one thing succeeding another, and each being required to remain for the student's observance, the whole unavoidably becomes intricate. Indeed, it is not now so perfectly executed but that

something remains for the student to complete, which must result from his own study or occupy more space than all we have already written on it. We allude to the intersections that take place at the lodgment of the spire on the top of the tower, to elucidate which it is drawn to a larger scale at No. 4., the mere inspection whereof will convey a full and, we hope, satisfactory idea of what we advert to. The student has been left to complete the base of the octagon, a process so simple that we cannot, if he retain what he has read, believe he will find difficulty in accomplishing, either by visual rays or otherwise. It is next to an impossibility to describe intricate matters like these so as to leave nothing for the exercise of the reader's judgment; for, however copious the instruction, there will always remain sufficient unexplained to keep his mind in action, and afford him the opportunity of exercising his own ingenuity.

2439. Example V. In *fig.* 833. the objects X and Y are plans of columns with bases

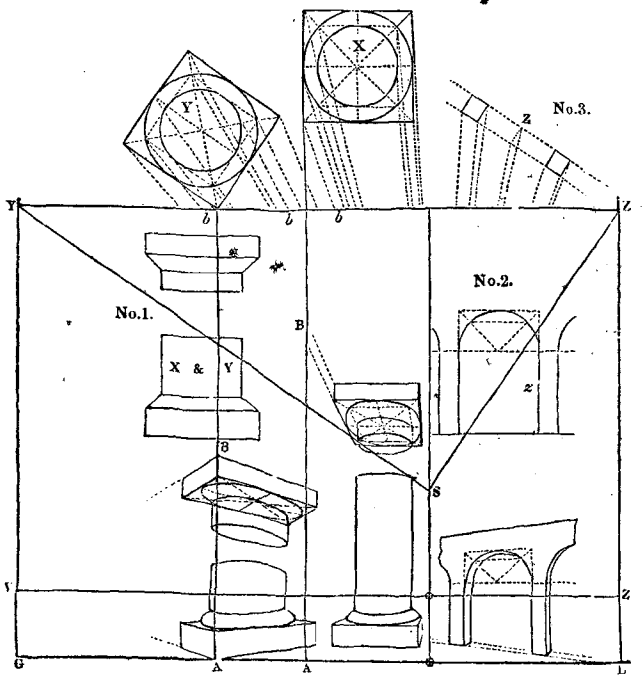

Fig. 833.

and capitals, whose general forms are shown at X and Y (No. 1.). YZ, as before, is the plane of the picture, S the station point. The picture, as previously, is prepared with the vanishing points VZ, and the ground line GL. OO is the central line of the picture, and BA, BA are, it will be seen, lines of height.

2440. In the squares X and Y the dotted lines show the diagonals and boundaries of squares inscribed in the circles, by which so many more lines are gained for obtaining the curves which the circles form in the perspective representations. The visual rays are drawn as in the preceding examples, and transferred to the picture, the process being, in fact, nothing more than making squares following the profiles, which, at the different heights, guide the formation of circles within and around them, of which the upper ones only, for preventing confusion, are shown in the perspective representation. In each series, the extreme width of the appearance of the circle may be obtained by visual rays, as at *b*, *b*, *b*.

2441. At Z and *z* (Nos. 3. and 2.) are the plan and elevation of an arcade, from which it will be seen that the principle of inscribing squares and diagonals is equally applicable to the vertical representation of circles. Presuming that we have sufficiently described the diagram to enable the student to proceed in drawing the examples at large, we shall now submit an example of general application.

2442. Example VI. In *fig.* 834. YZ is the plane of delineation, and the plan of the building, with its projections, roof, and chimneys, is shown in No. 1. In practice, this is generally made on a separate drawing board, to enable the draughtsman to make his perspective

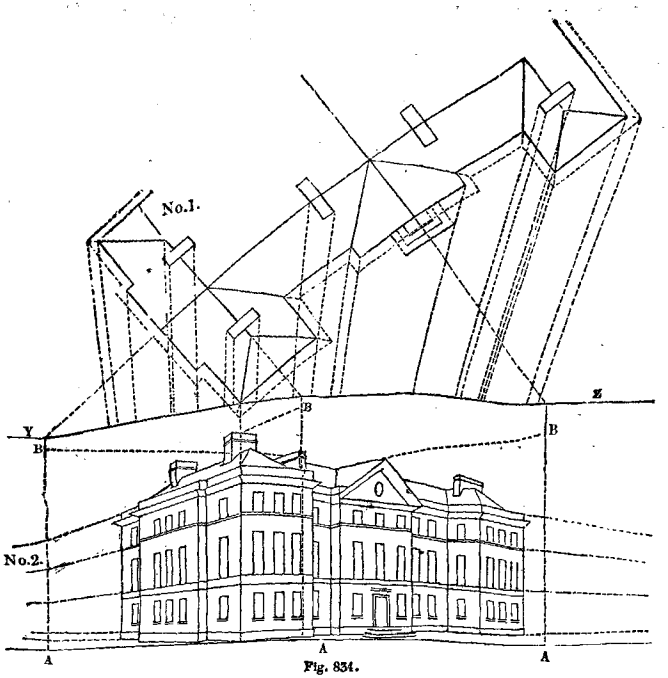

Fig. 834.

outline without injury from constantly working over the paper. Here the vanishing points are too distant to be shown on the diagram; but the reader, from the tendency of the several lines, will easily find where they lie. In the same manner, he will find whereabout the station point is placed. BA, BA, BA, No. 2., are lines for the transference of the heights. The projection of the cornice is dotted round the leading lines of the building on the plan. The rest of the figure cannot fail of being understood and put in practice by the student who has made himself master of the preceding examples.

2443. We shall now turn to a point whereon much difference of opinion has prevailed, namely, the adjustment of what may generally be considered the best angle of vision, within which objects should be seen to obtain the most agreable representation of them. For as this angle is enlarged or decreased by viewing the objects at greater or less distances, their appearance will vary, and their delineation, in consequence, be affected thereby, and distortion of the objects will be the result.

2444. By the angle of vision or angle of view is understood the expansion of the lines proceeding from the eye, by the two extreme visual rays embracing the whole extent of the view, and this whether it consists of one object or of many. Let A (*fig.* 835.) represent the plan of a mansion; let B be the outhouse contiguous to the mansion, and let the places of trees be at CCC and DDD. Let S be the station or point of view from which the whole is seen. Considering the mansion A as a lone object, the extreme visual rays S*a* S*b* form at the eye the angle *a*S*b*; then *a*S*b* is the angle of view under which that object is seen, S*a* and S*b* being the two extreme visual rays embracing the whole extent of the object. Again, if the outhouse B be taken as a single object, then will the extreme visual rays *c*S and *d*S form, at the eye, the angle *c*S*d*, being the magnitude of the angle under which that object is seen. So of any object, the visual rays that embrace its whole extent form the angle of view under which it is said to be seen. It is then manifest that the angle of view will be either large or small, as the eye is near to or remote from the object. Suppose both the objects A and B are to be taken into the view, with the ad-

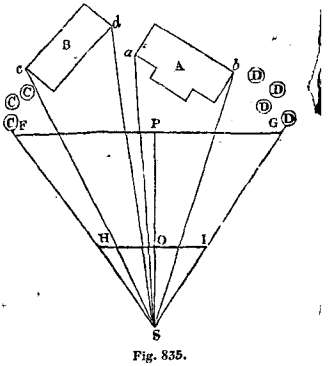

Fig. 835.

dition of the trees to their right and left. Let visual rays be drawn from the trees on both sides to the station S. The angle CSD is the angle of view under which the whole extent is seen, and the rays CS and DS are denominated the extreme visual rays of the view.

2445. Objects may not only be placed too near the eye for comfortably viewing them, but they may be so nearly placed to the eye as to give it pain. The eye only contemplates a small portion at a time; it is only by its celerity and continual motion that it becomes perfectly sensible of a whole and of the many forms whereof it is composed. But when an object, or many objects, widely extended, are placed too near, the traverses of the eye in viewing the whole become painful. Every one must have experienced that this is so, and why so we must leave to others to account for. When the eye is removed to an agreeable distance, the extent of the view to be delineated is at once seen without turning the head to one side or the other, so that all the objects are at once comprehended.

2446. In taking a view, the turning of the head is to be avoided. The view should on no account comprise a greater extent than can be taken by a *coup d'œil*, or than can be viewed by the traverse of the eye alone; and this necessarily confines the extent of that with which we have to deal, and brings the angle of view within certain limits. What the eye can contemplate without trouble it views with pleasure, and beyond a certain extent the eye becomes distracted.

2447. Smallness of object has no relation to the angle of view; a die, or the smallest possible object, may be brought so near the eye as to give pain in looking at it, and a large extent of view may be contemplated with as much ease as a small one, by merely placing the larger one at a greater distance. If the place of the plane of delineation be at FG, then FSG will be the angle of view. If a section of the same visual rays be taken at HI, then HI will be the extent of the picture, and the angle HSI is the angle of view; but the angles FSG and HSI are the same, therefore the eye views both with equal satisfaction: but in this case one must be placed at the distance SO, and the other at the distance SP.

2448. The attempt to select an angle suitable to all the cases that may occur, as the best angle of view, would be as vain as it would be absurd. Different subjects require different treatment. External subjects differ from internal ones; and the last from each other, according to circumstances. Some authors on the subject have laid it down as a rule, that the greatest distance of the eye from the picture should not exceed the width of the picture laterally, which makes the angle of view about 53 degrees; others have insisted that the distance should be less, requiring that the angle of view should not be smaller than 60 degrees; and others allow of a still larger angle. The elder Malton, and his son, to whom we are indebted for all that is valuable in this section, and whose (both of them) experience in the matter was very extended, advise that the angle of view should never exceed from 53 to 60 degrees; the former recommending an angle of 45 degrees as the best, because neither too large nor too small. The elder Malton advises to keep between the one and the other, that is, not to let the angle of view exceed 60 degrees, nor be less than 45, the first being likely to distort the objects, and the last rendering them too tame in the outline. We can add, from our own experience, that the advice is sound; for though, under very particular circumstances, it may be necessary to use a larger angle of view than 60 degrees, such a case does not frequently occur. Much must always be left to the discretion of the artist in respect to points which are to guide the angle of view he adopts. After a little experience, he will find that angle best suited to the circumstances under which his drawing is to exhibit the object or objects.

2449. Example VII. The principles upon which we delineate any of the interior parts of a building are in no wise different from those used for the representation of their external view, for it is of course immaterial whether we represent the external faces of their sides, or those which form their internal faces; the only difficulty which arises in making an internal view being that which arises from the inability, on account of the restricted distance under which they are in reality viewed, of placing the station point at such a distance as to take in a sufficient quantity of the objects to be represented. A person placed in a room can of course only see the whole of one and part of another wall; in short, in every direction he cannot see comfortably more than, as we have above mentioned, forty, or, at the most, fifty, degrees of the objects around him. On this account, and for the purpose of showing more than in reality can be seen, it is customary, and perhaps justifiable, in order to give a more comprehensive view of the interior to be delineated, to place the station point of the spectator out of the room or place, supposing one or more of its sides to be removed. This is, in fact, a delusion, as is every view of an interior possessing any merit that has come under our notice. But for picturesque delineation, it is not only one which is necessary, but one without the practice whereof no satisfactory representation can be given of an interior whose dimensions are not very extended. The section whereon we are now engaged is not supposed to be a treatise on Perspective, but merely a concise developement of its principles so as to give the reader such a general knowledge of the subject as may enable

him to pursue it, if he please, from the hints it affords. With this apology for not producing to him a more complicated, though not less useful subject, we proceed.

2450. *Fig.* 836. (No. 1.) represents the plan of a staircase one third the size used for the

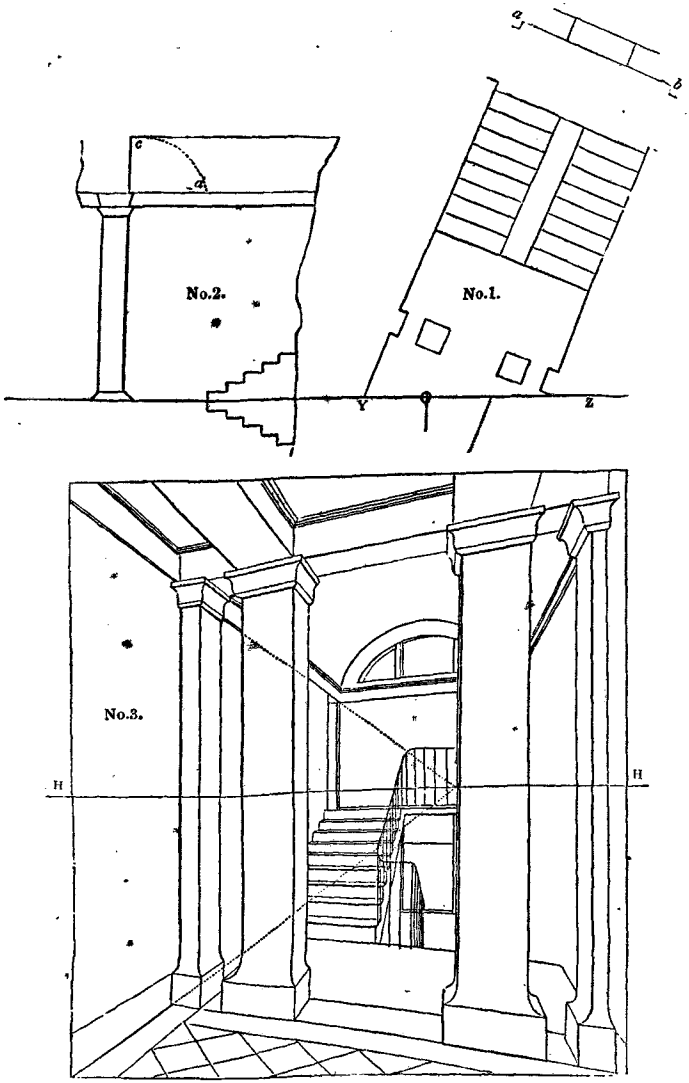

Fig. 836.

purposes of the delineation; YZ (No. 1.) is the plane of the picture, O is its centre. From the data, therefore, there will be no difficulty of obtaining the vanishing points of the sides Y*a* and *ab*. The diagram is not encumbered with the visual rays necessary for the delineation, which we are to suppose drawn and transferred to their proper places on No. 3., wherein HH is the horizontal line. No. 2. is a longitudinal section of the staircase, wherein are shown the rising and descending steps, and the dotted line *cd* gives the section of the vaulted ceiling over the staircase. It will be immediately seen that the ends of the steps will be determined by visual lines, notwithstanding the ascent and descent of them, because either is determined by referring to any lines of height, which may be obtained from the plan and section, by which the portions seen of the flights will be immediately found and

transferred to their respective places on the picture. With these observations we leave the diagram for the exercise, on a larger scale than here given, of the ingenuity of the student.

2451. Example VIII. The last perspective example to be submitted is that of a cornice

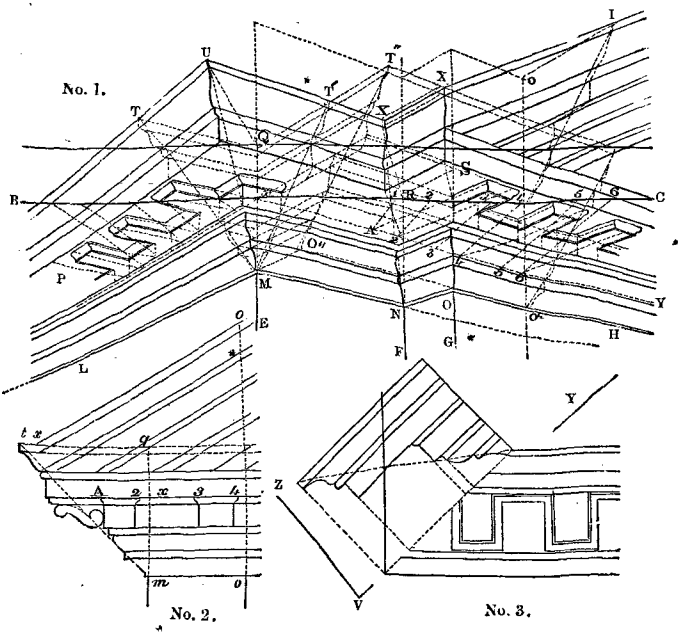

Fig. 837.

(*fig.* 837.), wherein the contrivance of the elder Malton is used for finding the places of the modillions and the other parts.

2452. Let EM, FN, GO (No. 1.) represent the angles of a building in perspective, LMNO being the lower horizontal line of the cornice, whose geometrical elevation and profile are shown in No. 2. Make MQ equal to *mq* the depth of the cornice, supposing the edge EQ to be in the plane of projection; draw PQRS, &c., the lines of the top of the cornice, to their respective vanishing points. Make QT, QT' in RQ, PQ, produced equal to the perspective projection of the cornice *qt*. Then place the depths of the various mouldings along MQ, and fix the lengths of their projections on the lines drawn to the vanishing points through those in EQ, an operation which may be much facilitated by drawing MT, MT', by which, in many places, the points of the mouldings are at once determined, as in the case of the top and bottom of the fillets of the ovolo; and very often, if the drawing is not on a very large scale, *mt* and its perspective images MT, MT', &c. will enable the eye to proportion the mouldings. Thus the perspective projections MQT, MQT' of the sections of the cornice by the planes of the sides EN, EL, supposed to be prolonged or extended, may be found; and it is manifest that lines through the points of these sections to the proper vanishing points will give the perspective forms of the cornice mouldings as they would appear.

2453. The lines found will by their intersections supply the mitre MQU; but where the scale is large, it is better to obtain mitre sections at each principal angle of the building as shown by the lines MQU, NRX, &c. The planes of the mitres form, of course, angles of forty-five degrees with the sides of the building itself, consequently the vanishing points of QU, RX, &c. may be found by bisecting perspectively the right angles found, or by drawing on the plan lines parallel to the diagonal lines or mitres from the station point to intersect the picture. If these, indeed, are found in the first place, there would be no necessity to draw the square sections MQT, MQT', inasmuch as lines drawn from the mouldings intersecting the mitre sections to the vanishing points will at once form the perspective representation of the cornice. In practice, this is the usual mode of proceeding, because a skilful draughtsman can pretty well proportion by his eye most mouldings as seen in perspective; but where great accuracy is required, the method of proceeding by square sections is recommended, because, from the great foreshortening of the diagonal line, the smallest inaccuracy of intersection on it will cause very large errors in the mouldings.

When the diagonal sections alone are used, it is clear that the geometrical profile, No. 2., will not be the same as that formed by the oblique section of the cornice: this last must therefore be obtained from a plan and elevation of the mouldings as shown in No. 3.

2454. Instead of finding the square section made by the plane FNGO at the angle OG, it may be drawn on the plane TQM, where it is more readily found by producing the lines whereby the section TQM was obtained; so the lines T′T″, MO″ are set out in perspective equal to the projection of the break of the building ON: moreover by the line T″O″ we may obtain the mouldings of the cornice on the face of the wall GH as produced or prolonged to T″O″, and conversely the cornice in perspective may be drawn from this imaginary section, if it be previously found. Where vanishing points are at an inconvenient distance in drawings, a mode may be adopted to obviate the inconvenience, the principle whereof is this. Let A (*fig.* 837 *a*.) be the vanishing point, CDB a segment of a circle whose centre is A; then if CB be bisected in D, AD will be a vanishing line for such bisection; and if CD be bisected, and a ruler applied to join CD, it will, by the application of a square on CD, give the vanishing line for the new bisection. *Fig.* 837. *b*.

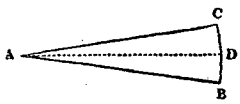

Fig. 837. *a*.

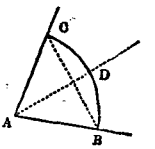

Fig. 837. *b*.

2455. Our next care is to find the vanishing point of the raking mouldings, which may be found from what has already been said, and a perspective section must be made of these mouldings by means of any vertical plane where most convenient; but the best place is through the apex of the pediment, which, as it could not, for want of room, be done in the present example, is taken through the line *oo*, No. 2., passing through the extreme left angle of the tympanum of the pediment.

2456. As the mouldings of the pediment (*fig.* 837.) here are of the same depth and projection as in the horizontal parts, they will not, when inclined, coincide with the diagonal section of the horizontal cornice at OS; hence that section, if found in perspective at OS, cannot be used for drawing the perspective representation of the pediment cornice, except for the bead or fillet above the corona, which, from the construction of the pediment, will coincide at this mitre, as we may see in No. 2.; whence it may also be seen that the point *x* does not coincide with *t*. X′*x* cannot, therefore, in the perspective representation, be drawn through X, the point answering to *t* in the diagonal section NRX. OO′ in the line OH is to be made in perspective equal to *mo*, No. 2., and the whole depth *oo*, and those of the several mouldings on the oblique section, being set upon EQ produced, they are to be transferred to OO′ by means of the vanishing points. The distance O′I is the perspective distance of the projection *qt* of the cornice as before, and is most readily obtained from the section O″T″, which is transferred to the plane O′I, and will be easily comprehended from the figure; the quantity of projection of each raking moulding of the pediment is equal to that of the same moulding where horizontal. Thus the perspective representation of an oblique section made by a plane passing through *oo*, No. 2., is obtained, and the mouldings are then drawn to the vanishing point through the various points, the line IX′ cutting T″X in the point corresponding to *x*, No. 2. As to the modillions, their representations are found with less confusion by planning them apart and using visual rays; but if no plan is used, the following method, invented by the elder Malton, may be adopted:—

2457. Draw BC, the line intersecting the plane of the sofite of the corona, Nos. 2. and 3., through the proper point *x* in MQ at right angles to it, and draw *xy* to the vanishing point. Produce the line corresponding to A in No. 3. to A in *xy*, and transfer A to 1 in BC, so as to be proportional to it in respect of the whole extent. Then set off the proportional widths and intervals of the modillions, as shown on Nos. 2. and 3. on BC, and transfer them by means of the same proportioning point by which *x* was transferred to 1; and from the points 2, 3, 4, 5, 6, &c. in *xy* thus obtained, draw on the perspective of the sofite by the use of the vanishing point the lines representing the tops of the modillions corresponding to 2, 3, 4, &c., No. 2. The cymatium round them and the inner angle of the sofite may be drawn by the eye, or where great accuracy is required, the mitre or diagonal sections may be determined as for the principal mouldings already described. At the backs of the modillions the verticals are to be determined either by means of visual rays from a plan, or through the medium of intersections of the perspective lines of the upper parts of them on the sofite, which is as much as can be requisite for guiding us to a correct delineation. The same process is to be used for the modillions on the other sides.

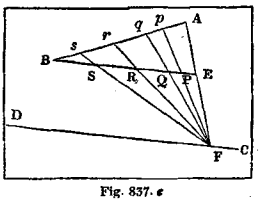

Fig. 837. *c*

The following is an easy method for dividing vanishing lines in perspective. Let AB, CD be the perspective representation of two parallels, no matter in what plane. It is required to divide the given portion of AB on one of them so that its parts shall be the perspective representation of equal portions of the real line (or in any assigned ratio). Draw BE parallel to CD and equal to AB, and divide it into the required number of equal parts or of parts in the desired proportion beginning at E. Join AE and produce it to meet CD in F. From F draw lines to each of the points of division PQRS of the line AE, and they will cut AB in the required points of subdivision *p q r s*.

Sect. III.

SHADOWS.

2458. Sciography, or the doctrine of shadows, is a branch of the science of projection, and some preparation has been made for its introduction here in Sect. VI. Chap. I. (1110, *et. seq.*) on Descriptive Geometry, which, if well understood, will remove all difficulty in comprehending the subject of this section.

2459. The reader will understand that in this work, which is strictly architectural, the only source of light to be considered is the sun, whose rays, owing to his great distance, are apparently parallel and rectilineal. It is moreover to be premised, that such parts of any body as may be immediately opposed to the rays of light are technically said to be *in*

light, and the remaining parts of such body are said to be *in shade*. But when one body stands on or before another, and intercepts the sun's rays from the latter, which is thereby deprived of the action upon it of the rays of light, the part so deprived of the immediate action of the light is said to be *in shadow*. It seems hardly necessary to observe, that the parts of any body nearest the source of light will be the brightest in appearance, whilst those furthest removed from it will, unless under the action of reflected light, be the darkest.

2460. It has been the practice, in architectural drawings, to represent the shadows of their objects at an angle of forty-five degrees with the horizon, as well on the elevations as on the plans. The practice has this great convenience, namely, that the breadth of the shadow cast will then actually measure the depth of each projecting member which casts it, and the shadowed elevation may be thus made to supply a plan of the external parts of the building. Now, if in the elevation the shadows be cast at an angle of forty-five degrees, it will on a little consideration be manifest, that, being only projections of a more lengthened shadow (for those on the plan are at an angle of forty-five degrees), the actual shadow seen diagonally must be at such an angle as will make its projection equal to forty-five degrees upon the elevation; because all elevations, sections, and plans, being themselves nothing more than projections of the objects they represent, are determined by perpendicular, horizontal, or inclined parallel lines drawn from the points which bound them to the plane of projection, and similarly, a shadow in vertical projection, which forms an angle of forty-five degrees with the horizon, can only be the representation on such projection of an angle, whose measure it is our business now to determine.

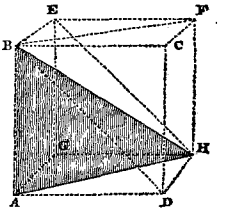

Fig. 838.

2461. In the cube ABCDEFGH (*fig.* 838.) the line BD, forming an angle of forty-five degrees with the horizon, is a projection or representation of the diagonal BH on the vertical plane ABD; and our object being to find the actual angle AHB, whereof the angle ADB is the projection, we have the following method. Let each side of the cube, for example, =10. Then (by 907.) $AD^2 + DH^2 = AH^2$.

That is, $10 \times 10 + 10 \times 10 = 200 = AH^2$, consequently AH = 14·142100.

As BAH is a right angle, we have by Trigonometry, using a table of logarithms, —

As AH (=14·14142100) or Ar. Co. Log. .	9·8494850
To tangent 45°	10·0000000
So AB (=10·00000000) log. . .	1·0000000
To tangent of angle FHB=35° 16′ . .	=9·8494850

The angle ABH is therefore 54° 44′.

Hence it follows, that when shadows are projected on the plan as well as on the elevation, at an angle of forty-five degrees, the height of the sun which projects them must be 35° 16′.

2462. It is of the utmost importance to the student to recollect this fact, because it will be hereafter seen that it will give him great facility in obviating difficulty where confusion of lines may lead him astray, being, in fact, not only a check, but an assistance in proving the accuracy of his work.

2463. We now proceed to submit to the student a series of examples, containing the most common cases of shadowing, and which, once well understood, will enable him to execute any other case that may be presented to his notice.

2464. In *fig.* 839. we have on the left-hand side of the diagram the common astragal fillet and cavetto occurring in the Tuscan and other pilasters, above in elevation and below in plan. The right-hand part shows the same connected with a wall, whereon a shadow is cast by the several parts. LL is a line showing the direction of the light in projection at an angle of forty-five degrees. It will on experiment be found, by a continuation of the line, or by one parallel to it, to touch the side of the astragal at a, whence an horizontal line drawn along it will determine its line of shade. We here again repeat, to prevent misunderstanding, that in the matter we are now attempting to explain we are not dealing with reflected light, nor with the softening off of shadows apparent in convex objects, but are about to

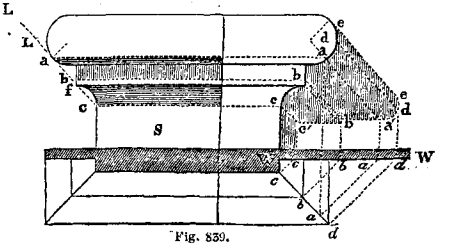

Fig. 839.

determine the mere boundaries of *shade* and *shadow* of those under consideration. The rest must be learned from observation, for the circumstances under which they are seen must constantly vary. This, however, we think, we may safely state, that if the boundaries of shade and shadow only be accurately given in a drawing (however complex), the satisfaction they will afford to the spectator will be sufficient, without further refinement. But it is not to be understood from this that we discountenance the refinement of finish in architectural subjects; all that we mean to say is, that it is not necessary. To return to the diagram: it is manifest that if the boundary of *shade* be at a from that point parallel to the direction of the light a line ab will determine the boundary of *shadow* on the fillet at b, and that from the lower edge of such fillet at f a line again parallel to the direction of the light will give at c the boundary of the shadow it casts upon the shaft S. As, in the foregoing explanation, a was the upper boundary of shade, so by producing the horizontal line which it gave to a on the right-hand side of the diagram we obtain there a corresponding point whence a line aa′ parallel to the direction of the light is to be drawn indefinitely; and on the plan a line *aa*, also parallel to the direction of the light, cutting the wall WW whereon the shadow is cast at *a*. From the point last found a vertical line from *a*, where the shadow cuts the wall on the plan, cutting aa′ in a′, will determine the point a′ in the shadow. The point e, by a line therefrom parallel to the direction of the light, will determine similarly the situation e′ by obtaining its relative seat on the diagonal *cd*, which perhaps will be at once seen by taking the extreme point d of the projection of the astragal, and therefrom drawing dd′ parallel to the direction of the light. From the line *dd*, drawn similarly parallel to the direction of the light, and cutting WW in *d*, we have the boundary of the shadow on the plan, and from that point a vertical *dd* being drawn, the boundary of shadow of the extreme projection of the astragal is thus obtained. The boundary of shadow of the fillet on the right-hand side at *b*, similarly by means of *bb*, and by the vertical *bb*′, gives the boundary point of the shadow from b. The same operation in respect of *cc* gives the boundary of shadow from c to c′ in the latter point. We have not described this process in a strictly mathematical manner, because our desire is rather to lead the student to think for himself a little in conducting it; but we cannot suppose the matter will not be perfectly understood by him even on a simple inspection of the diagram.

2465. In the diagram (*fig.* 840.) is represented a moulding of common occurrence in architectural subjects, and, as before, the right-hand side is the appearance of its shadow on the wall WW on the plan. It will be immediately seen that LL being the projected representation of the rays of light, the line aa determines the boundary of shadow on the ovolo, and that at b, the boundary of its shade, is also given by a line touching that point parallel to the rays, or rather projected rays, of light. On the right-hand side of the figure oo′, drawn indefinitely parallel to the direction of the light, and determined by a vertical from *a*″, the intersection by *a*″*a*″ with the wall, will give o′a″, the line of shadow of oa′. The line aa determines the shadow on the ovolo, and this continued to a′ horizontally gives also a like termination to a″ in the shadow; b, the boundary upwards of the ovolo's shade, is represented to the right by b′, and to the right on the plan by *b*, whence by a vertical cutting the line b′b″ in b″, the boundary of shadow which b′ will cast is obtained. *cc* on the plan is in projection the distance of the line of shade c′ from the wall whereon the shadow is cast, and its place in the shadow is at c″, ee″b″ being the length of horizontal shadow produced by the circumstances.

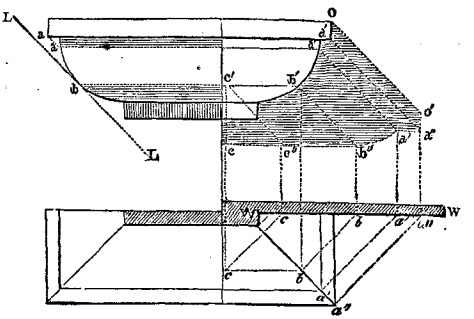

Fig. 840.

In *fig.* 841., which, it will be seen, is a common fillet and cavetto, LL is, as before, the direction of the

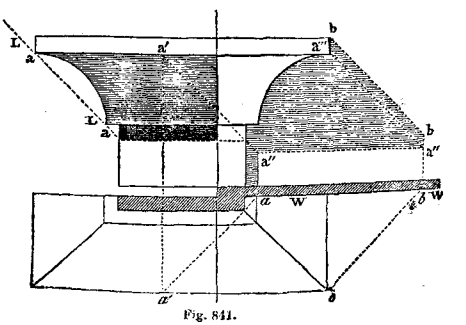

Fig. 841.

light, and aa gives the boundary of shadow, as well of the fillet's lower edge as of the lower edge of the cavetto itself. In respect of the right-hand side of the figure, a′a′ is a line showing in profile the extent of projection of the fillet before the wall WW, and from a′ a line drawn indefinitely parallel to the direction of the light, and terminated by the intersection of a vertical from *a′* in *a″*, will give the point a′ in the shadow. So is bb found through a vertical from *b* on the wall, by a line drawn parallel to the direction of the light from *b* on the plan. The several points being connected by lines, we gain the boundaries of the shadow, wherein a′a‴ is represented by a″a″.

2466. *Fig.* 842. exhibits a fillet and cyma reversa or ogee, wherein, as before, LL is the direction of the light at a similar angle to that used on the plan. From the lower edge of the fillet, parallel to the direction of the light, is obtained the point a on the ogee, and from b a similarly parallel line gives the boundary of shadow in c. A line from o in direction of the light, drawn indefinitely, intercepted by a vertical line from *d′*, its projection on the plan in *d* determines o′d, the boundary of the shadow of the fillet on the wall WW. cc‴ is the line of profile of the projecting boundary in elevation, of the shade of the ogee before the wall, whereon its shadow is terminated from *c* and *c‴* by a vertical *c‴ c‴*. bb′, the boundary of shade of the ogee itself, is found in shadow by the line b′b‴ drawn indefinitely parallel to the direction of the light, and terminated by a vertical from *b′*, the point on the wall correspondent to *b* on the plan, the place of the shade's point in the elevation. By the junction of the lines so found, we shall have the outline of the shades and shadows cast. It is here to be observed, that the portion of light a′b′ which the moulding retains is represented in the shadow by a″b‴, all the other parts of its curved form being hidden, first by the projection of the fillet, and secondly by the line of shade bb″, which acts in the same way as the fillet itself in producing the line aa′, for the moment the light is intercepted, whether by a straight or curved profile, shadow must follow the shade of the moulding, whatever it be; and this is by the student to be especially observed.

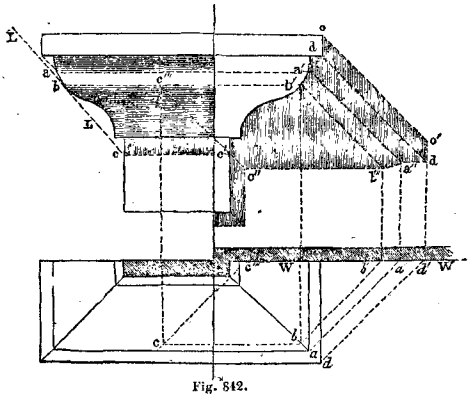

Fig. 842.

2467. *Fig.* 843. exhibits the mode of obtaining the shadows and shade in the cyma recta. LL is the direction of the light, parallel whereto the line ab determines the line of horizontal shadow cast by the lower edge of the fillet upon the cyma, and ed that of the under part of the cyma itself upon the fillet at d. cc′ is the upper boundary of the shade of the cyma, and e the point for determining the shadow of the lower fillet, the points abcd corresponding with *abcd* on the plan. WW on the right hand is the face of the wall, whereto the lines *e′e″*, *d′d″*, *c′c″*, *b′b″*, and *a′a″* are drawn parallel to the direction of the light. From *e″d″c″b″a″* vertical being drawn, cutting the indefinite lines oo′, a′a″, &c. parallel to the direction of the light in e″, d‴, c″, b″, and a″, we have the form of the shadow in elevation. The part from b′ to c′ of the cyma being in light, its shadow will be the curve c″b″, wherein, if it be required on a large scale, any number of points may be taken to determine its form by means of correspondent points on the plan as for the parts already described.

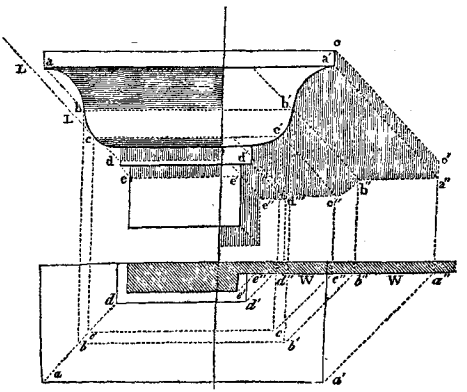

Fig. 843.

2468. *Fig.* 844. is the plan and elevation of some steps, surrounded by a wall, and P in the plan is a square pillar standing in front of them. It will be seen that the line AB

corresponds with ab on the plan, as do the points E, F, G, H with efgh, from which verticals determine them in the elevation. The projection of the plinth on the lower step is found by KJ and a corresponding line and vertical, which, to prevent confusion, is not shown on the plan. The shadow of the square pillar P is found in a similar manner by the line CD corresponding to cd on the plan, the shadows on the steps being also determined by the points L, M, N, O, through the medium of verticals from l, m, n, o. The left-hand side of the shadow of the pillar is determined in a similar way by the line pq, and QR in the elevation is given by qr in the plan, and is the line representing the back ps of the top of the pillar. It will be observed that we have not described any of the preceding diagrams in a strict way, neither shall we do so in those that follow, presuming that the reader has, from the perusal of the section on Descriptive Geometry acquired sufficient knowledge to follow the several lines.

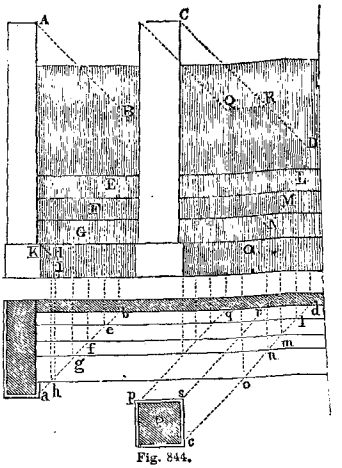

Fig. 844.

2469. The *fig.* 845. is a sort of skeleton plan and elevation of a modillion cornice, but deprived

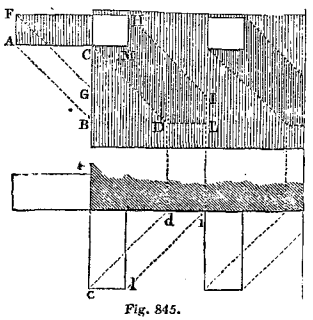

Fig. 845.

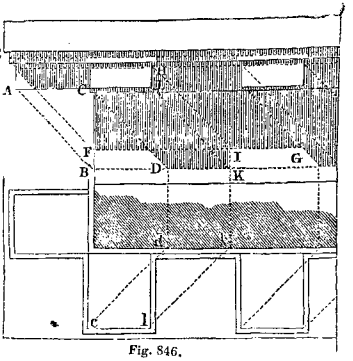

Fig. 846.

of a corona, so as to show the shadows of the modillions, independent of any connection with other parts of the assemblage. FG, HI, and AB parallel to the direction of the light determine, by means of verticals from d and i, the points of shadows from the correspondent points c, l, the points D, L, and I, whereof L is the point of shadow of M.

2470. In *fig.* 846. we approach a little nearer to the form of a modillion cornice. The line EF determines the shadow of the corona, and AB by means of the lines cd, Ik, and the verticals dD, kK, the boundary of the side HL of the modillions. A line also drawn horizontally from B will give the under sides of their shadows. FG is a line representing the shadow of the corona.

2471. *Fig.* 847. gives the finished modillion, and the lines Aa, Bb, Cc, Dd will determine, by horizontal lines drawn from them, the shadows which we are seeking. The auxiliary lines, to which no letters are attached, cannot fail of being understood; but if difficulty arise in comprehending them, it will be removed by planning the several points, and therefrom drawing on the plan, to meet what may be called the frieze, vertical lines to intercept those from the correspondent points in the elevation, and the operation will be facilitated, perhaps, by projecting the form of the curved lines (as seen in the figure) whereof the modillion is formed.

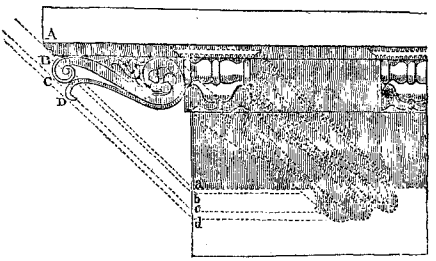

Fig. 847.

2472. *Fig.* 848. will scarcely require a description. It is a geometrical elevation of the

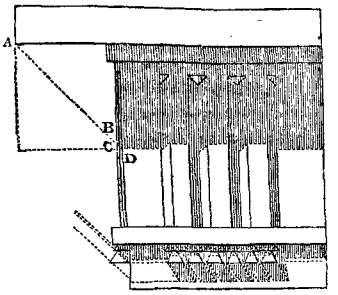

Fig. 848.

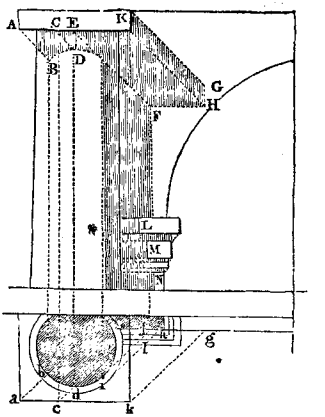

Fig. 849.

Doric triglyph and frieze, with the usual accessories. AB gives the boundary of shadow on the femora of the triglyph, AC the boundary of shadow on the light sides of the glyphs, and AD of the shadow of the corona on the frieze.

2473. *Fig.* 849. is a skeleton representation of a three-quarter column, forming part of an arcade. The abacus is the mere block of material AK. In the plan ab shows the length of the line of shadow AB, and is determined by the vertical bB. In the same way, CD is found by cd and the vertical dD. KG is the representation of kg on the plan, and by a vertical from g the line GH is also determined; H giving also by the horizontal line FH, in which H is already found, the situation of shadow of the point E of the abacus, as also by a vertical from f. LMN are places of the shadow of the column on the impost moulding of the arch, whereof two correspondent points are seen in l and n.

2474. The form of shadow of the console in *fig.* 850. will be seen on inspection to have been found from the lines aa, cc, dd, &c. on the elevation, corresponding with *aa*, *cc*, *dd*, &c. on the section, all which are parallel to the direction of the light, and sufficiently explain themselves.

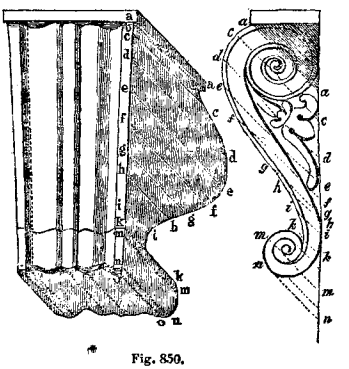

Fig. 850.

2475. *Fig.* 851. is the elevation and section of a hemispherical niche, wherein are shown the shadows cast thereon by the vertical wall in which it is placed. Through the centre O draw DD at right angles to the direction of the light, and from O draw OA parallel to the direction of the light: A will be found the point in the wall casting the longest shadow. Produce AO indefinitely; and from a, the corresponding point in the section to A on the elevation, draw aa′, parallel to it, which will cut the surface of the niche in a′. Draw the horizontal line a′ a″ cutting AO produced in a‴; and a″ will represent in the shadow the point A in the circumference. Take any other point B in the edge of the niche, and by means of a line drawn therefrom horizontally we have the correspondent point b of B in the section. From B draw in the direction of the light the line Bb‴ b′, cutting DD on the diameter in b‴; transfer the point b‴ in the elevation to *b* in the section, and draw bb′ in the direction of the light indefinitely. Then with Bb‴ as a radius from *b* as a centre, describe an arc cutting bb′ in b′; and from b′ draw the horizontal line b′ b″, cutting Bb‴ produced in b″, and b″ will be the point in the shadow corresponding to B in the elevation. To avoid the confusion which

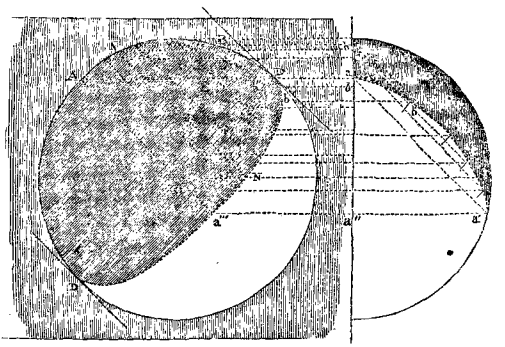

Fig. 851.

would follow the description of the remainder of the operation, we have not encumbered the diagram with more letters of reference; the lines showing, on inspection, similar applications of the process for all parts of the curve. The fact is, that the whole of the shadow may be completed by taking the line DD as the transverse axis of an ellipsis, and finding the semi-conjugate axis Oa by the means above described, for Da″D is a semi-ellipsis in form, inasmuch as it is the projection of a section of a hemisphere. This example is applicable to the shadow of a cylindrical niche with a hemispherical head. The line NN shows the shadow of the portion of the head, and the remainder is obtained by the mere intersection of lines in the direction of the light from different points to the left of N, of which enough has been already given in the previous examples to make the application intelligible.

2476. *Fig.* 852. is the representation of a pediment wherein the section A is that of the

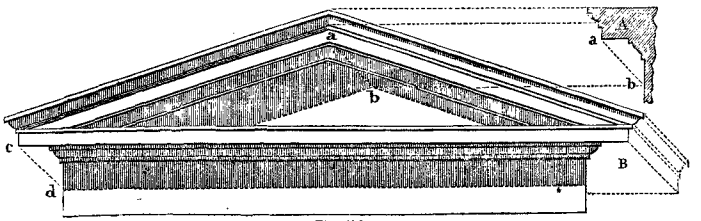

Fig. 852.

mouldings of the pediment at its apex. In the section, ab drawn from the projection a of the corona in the direction of the light, determines the point b therein, wherefrom the horizontal line intercepted by the line ab in the elevation, also drawn parallel to the direction of the light, gives the point b in the elevation. A line from b, parallel to the inclined sides of the pediment on the left, will give the shadow of the corona on the tympanum on that side, and similarly the line of shadow from b on the right side. cd determines the line of shadow on the frieze, and B is the section of the shadow of the assemblage of mouldings on the right.

2477. In *fig.* 853. is given the plan, elevation, and section of a square recess, covered with a cylindrical head. The lines AA, BB, CC of the elevation are determined by aa, bb, and cc of the plan; and in the section c′c′ is the representation of the line cc of the plan. D, the point at which the direction of the light begins to touch the circular head, is d′ in the section.

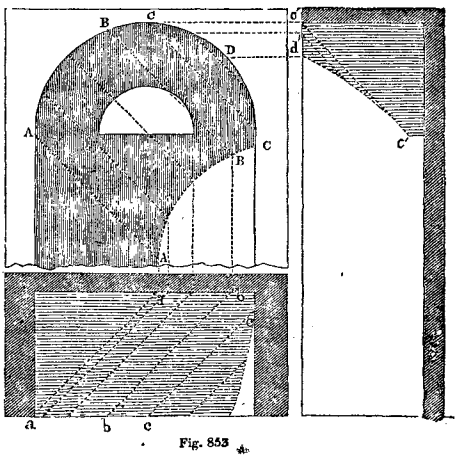

Fig. 853

2478. *Fig.* 854. is the elevation of an arch, below which is its plan and the shadow cast by it on the plane upon which it stands. AA is shown by *aa* on the plan, the corresponding points in the rear of the arch being *a′ a′*, and *a″ a″* the points in the shadow. In a similar way, by BB corresponding with *bb′* on the plan the points *b″ b″* are obtained in the shadow.

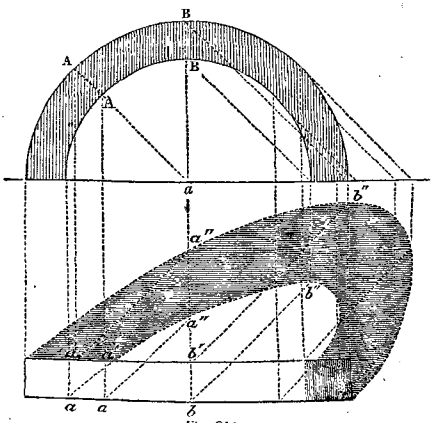

Fig. 854

2479. *Fig.* 855. is the plan and elevation of the upper part of a house,

wherein the upper story is occupied by an attic in the centre, against which, on each flank, the sloping roof is terminated. aa on the plan in the direction of the light, produced to intersect the hip at b, gives, by a vertical to B on the elevation, the direction BB of the shadow thereon; and BB cut by AA in the direction of the light, the length BA of the line of shadow, which may, by letting fall the vertical Aa, determine the length aa on the plan. The line of shadow ac is determined by letting fall a vertical from C, where the line of shadow is intercepted by the hip of the roof; and from c the shadow will be found on trial to return as shown in the diagram. E and D on the elevation are found,

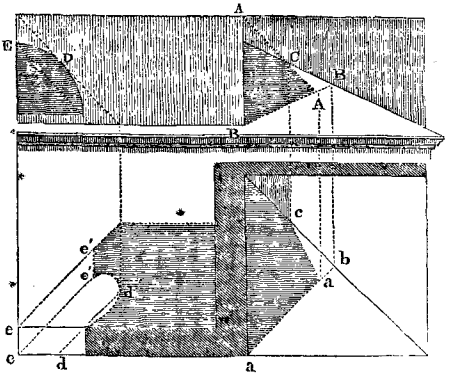

Fig. 855.

as seen in previous examples, in ee, and d on the plan, and their shadows at e'e' and d'.

2480. What is called an attic base is given in plan and elevation by *fig.* 856. The method of obtaining the shadows thereof in plan and elevation is now to be explained. It is an example which constantly occurs in architectural subjects, and should be well studied and understood. The operations requisite for obtaining a representation of the lines of shadow of the different mouldings in this example depend upon the principles developed in the preceding subsections. The lower portion of the figure exhibits the plan, and the middle portion the elevation of the attic base in question. The uppermost portion of it presents three sections of the mouldings of the base in question cut in three different places parallel to the direction of the light. This last portion of the figure is not absolutely necessary, inasmuch as the profiles in question might have been obtained upon the elevation; but we have preferred keeping it separate to prevent a confusion of subsidiary lines. There is moreover another advantage in thus separating the parts from each other, namely, that of immediately and more distinctly seeing the lines at each selected place, in which the rays of light separate the parts actually in light from those in shadow; and where the student is likely to meet with

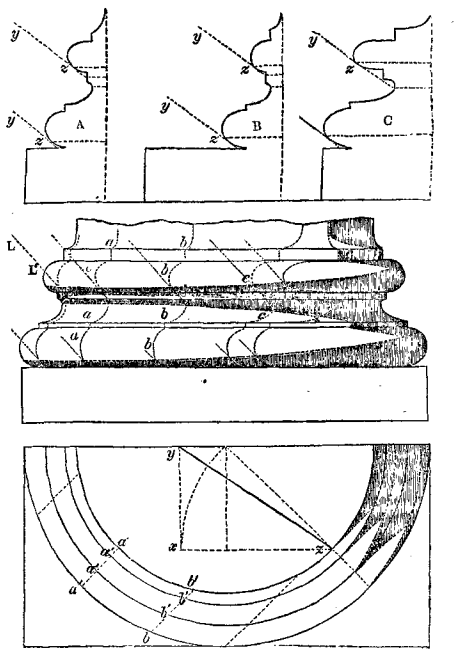

Fig. 856.

matters of perplexity, nothing should be left untried to save his time, and, what is often more important, his patience. The mode to be adopted is as follows:—

Make on the plan any number of sections *a'a'a'a'*, *b'b'b'b'* in the direction of the light, and draw on the elevation the corresponding sections *aaaa*, *bbbb*. LL being the direction of the light, draw parallel thereto tangents to the curves of the convex mouldings, and the boundaries of their shades will be obtained, as will also those of their shadows, by continuing them from such boundaries till they cut the other parts in each section, as will be more especially seen at *cc*. It will be recollected that in our first mention of the projected representation of the line of light and shadow we found that it was an angle of 54° 44′ of the diagonal of a cube. This angle is set out in *xyz* on the plan. We have therefore another mode of finding the boundaries of shade and shadow on the moulding, by developing the sections *a'a'a'a'*, *b'b'b'b'*, &c., as at A, B, and C, and drawing tangents *yz* to the convex mouldings for

boundaries of shade thereon, and continuing them, or otherwise, for the other parts, as shown in the diagram.

2481. In *fig.* 857., which represents the capital of a column, a similar method is used to that last mentioned for obtaining the shades and shadows, by means of *a'a'a'a'* and *b'b'b'b'*, which are shown on the elevation by *aaaa* and *bbbb*. We apprehend this will be understood by little more than inspection of it.

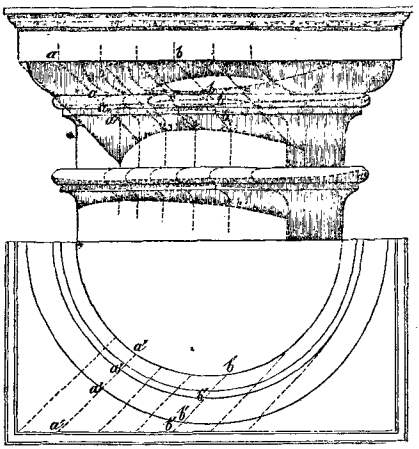

Fig. 857.

It is obvious that the means here adopted for obtaining the lines of shadow are precisely similar to those used in the preceding example. In this, however, the sections of the capital parallel to the direction of the light are made on the elevation, and it will be seen that many of them are not required to obtain an accurate boundary of the lines of shadow sought; for after having obtained those points from which the longest shadow falls, and on the other side those where the line of shadow commences, a curve line of an elliptical nature connects the points found. If the drawing to be made be on a large scale, it may then be worth the architect's while to increase the number of points wherefrom the shadow is to be projected, so as to produce the greatest possible accuracy in the representation.

2482. The shadows of an Ionic capital are given in *fig.* 858. The shadow of the volute on the column is obtained by any number of lines AA, BB, CC, &c. from its different

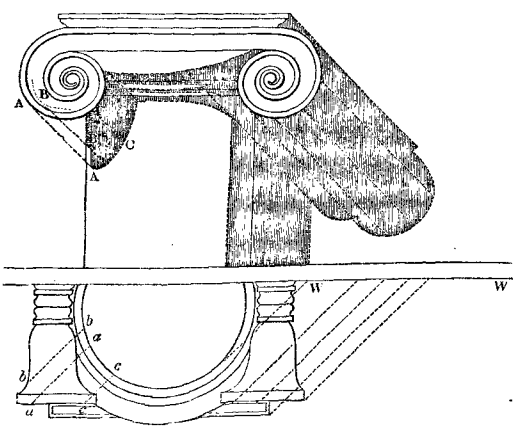

Fig. 858.

parts and verticals from their corresponding ones *aa*, *bb*, *cc*, &c. on the plan, and similarly the shadow of the capital on the wall. In this example, as in those immediately preceding, the employment of sectional lines parallel to the direction of the light is again manifest. The use of them is most especially seen in the example of the Corinthian capital which follows. As a general rule, it may be hinted to the student of sciography, that in the difficulties that may occur, they will be most expeditiously and clearly resolved by the use of the sectional lines, whereon we have thought it proper so much to dilate.

2483. The Corinthian capital in *fig.* 859. will require little more than inspection to understand the construction of its sciography; and all that we think necessary to particularise are the developed projections A, B, C, D, E, F of the abacus and the leaves, whereon the termination of the shadows at angles of 54° 44′, as explained in *fig.* 856., give their respective depths on the elevation.

There is another method of arriving at the result here exhibited, by drawing sectional lines parallel to the direction of the light through the different parts and leaves of the

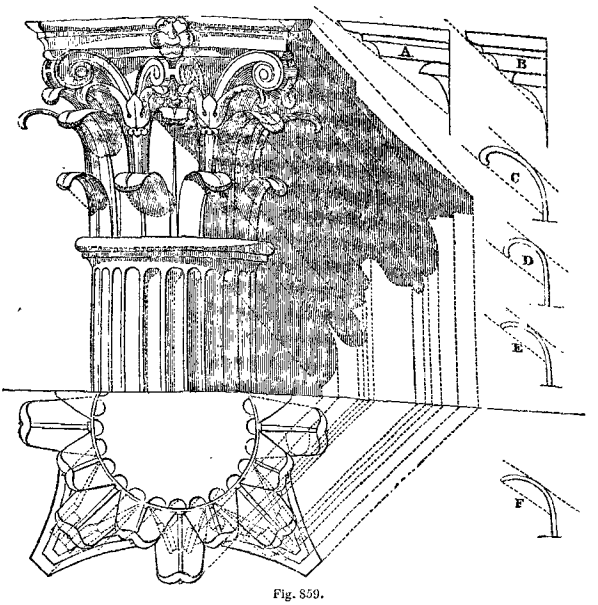

Fig. 859.

capital on its elevation, as in *fig.* 857., and such was the mode we were formerly in the habit of adopting. It however induces such a confusion of lines, that we have long since abandoned it, and have no hesitation in recommending the process here given as the best and most likely to avoid confusion. It is of course unnecessary, in making drawings, to project more than the shadow of one capital, as in a portico, or elsewhere, similar capitals, similarly exposed to the light, will project similar shadows, so that the projection on one serves for the projection on all of them.

2484. For instruction upon the mode in which reflected light acts upon objects in shade and shadow, we must refer the learner to the contemplation of similar objects in relief. The varieties of reflexes are almost infinite; and though general rules might be laid down, they would necessarily be so complicated, that they would rather puzzle than instruct, and under this head we recommend the study of nature, which will be found the best instructress the student can procure.

SECT. IV.

GENERAL PRINCIPLES OF COMPOSITION.

2485. The end of architecture, without whose aid no other art can exist, is not merely to please the eye, but so to provide against the changes of the seasons as to be serviceable to man. Pleasure to the eye may, however, result from the useful, well combined with the beautiful modifications whereof it is susceptible. It is in combining thus that the genius of the architect is exhibited. The art of decorating a well-proportioned edifice is a very secondary and comparatively easy part of his work, though requiring, of course, the early cultivation of his taste and an intimate acquaintance with the parts, whereof this may be taught and that acquired; but the distribution and arrangement of the several portions on the plan, upon which every accessory is dependent, requires great knowledge and considerable experience. And in this is involved not only the general convenience and effect of the building, but what is of much consequence to the proprietor, the cost of the work. None but those practically conversant with the planning of a building would believe the saving that may be produced by proper distribution. In the case of many external breaks, for instance, much addition arises in the length of walls enclosing the edifice, without generally increasing the convenience of the interior, but always when the elevation comes to be adapted to the plan, with the certainty of breaking up the masses, and destroying the simplicity of the effect. This is mentioned merely as an instance of simplicity of plan always producing simplicity of section and elevation.

2486. All ornament in architecture is non-essential, inasmuch as the pleasure received by the eye is not its end. To public and private utility, the welfare and comforts of individuals, which are the ends of the art, every other point must be sacrificed; and it is only when these have been accomplished that we are to think of decoration. An anecdote is related of a certain nobleman, who, having boasted to a friend of the beauty of the façade of his house, which within was exceedingly ill contrived, was told that he thought the peer would do well to take the house opposite, that he might be thus always able to look at it. Those who make the internal parts of an edifice subservient to the project of a façade, and adjust their plan and section to the elevation, must be considered as making the end of less importance than the ornament of the building. Those who work in this mode produce little variety in their designs, which, numerous though they be, consist of but few different combinations, whilst those that result from the natural order of making the façade subservient to the internal parts, which the plan and section impose, are susceptible of infinite variety and decoration.

2487. It is not, however, to be supposed that we are, in what has been said, sanctioning the student's neglect of careful composition and adjustment of the façades. Upon the adaptation of the different fronts of the building to sort with the internal convenience, the greatest care should be bestowed. It is from these his reputation is likely to flow, because they are the parts most susceptible of comprehension by the public. The architect will, upon every succeeding day's experience, find that the two objects are not incompatible; but if such a case, which is possible, arise, he had far better sacrifice the façade, considering first the comforts of those who are to inhabit the house, and then the gratification of those who are only to look at it.

2488. Durand has well observed that compositions conducted on the above principles must please. "Has not nature," says that author, "attached pleasure to the satisfaction of our wants, and are our most lively pleasures other than the satisfaction of our most pressing wants? These wants are better satisfied in the interior distribution of a building than in the exterior." Who leaves the Pantheon without more satisfaction than he expected from the view of the portico, fine though it be? Again, faulty as are both St. Peter's and St. Paul's, will any one who understands the subject aver that he has received more pleasure from their respective façades than from their noble interiors? The pleasurable sensations produced by both are entirely dependent on their interior distribution. But when we find that in the former of these buildings there is no mockery of a dome, the interior and exterior being as far dependent on each other as the circumstances of construction would permit, whilst the dome of the latter is worse than a mockery, the interior and exterior domes having nothing in common with each other, the last being no more than a timber leaded appurtenance to the fabric, Wren, with all his greatness, for great he was, shrinks into nothingness by the side of Michael Angelo, although the external form of the dome of London be more elegant than that of the Vatican. This is a strong but not a forced illustration of our opinions, the good sense whereof must be left for appreciation to our readers, who, we doubt not, on a little reflection, will concur with us.

2489. In ninety-nine cases out of a hundred the student will find that a good distribution of his plan leads him, with anything like ordinary tact, to the composition of good sections and good elevations, far better, indeed, than he could arrive at by pursuing an opposite course. In domestic Gothic architecture, this is notorious, for in that a regular distribution of the openings would often produce the tamest and least picturesque effect. The Gothic architects placed windows internally where only they would be serviceable, letting them take their chance in the exterior. It is not to be understood, because such would be rather *outré*, that this method will exactly suit the principles of composition in Italian architecture; but it is well known to practical men that a required opening in a particular place, instead of being a blemish, may be converted on many occasions into a beauty. Indeed, it is incontrovertibly true that distribution and disposition are the first objects that should engage the architect's attention, even of him whose great aim is to strike the attention by ornament, which can never please unless its source can be traced to the most convenient and economical distribution of the leading parts. Theorists may be laughed at, but it does not move us, nor diminish our regret to see many architects without any other theory than that whereon, in an inverted position, their own wild fancies are grafted. If what we have stated be true, and from the nature of things we cannot imagine a controversy can arise upon our observations, the talent of the architect is to be estimated, as Durand properly observes, according to his solution of the two following problems: —

First. For a given sum, as in private buildings, to erect the most convenient and suitable house for his employer.

Second. The requisites in a building being given, as in public buildings, to erect it at the smallest possible expense.

2490. An investigation of all the modes of accomplishing these desiderata can only be fully effected in a work of much larger extent than this; but we have, in the practical parts of our volume, so prepared the reader, that he will not generally be at a loss in respect of the construction of a building, whatever its nature or destination.

SECT. V.

DRAWINGS NECESSARY IN COMPOSITION.

2490*a*. For the thorough comprehension of a projected edifice, at least three drawings are necessary, the *plan*, the *section*, and the *elevation*. The first is a horizontal section of it, the second the vertical section, which shows the building as if it were cut in half, that half nearest the spectator being removed from its plan, so as to permit the inner parts to become visible, and the third is the geometrical appearance of the front represented as if viewed from an infinite distance, in which no convergence of the lines would be seen.

2490*b*. In making a design, it is always better to put the general idea together on a single sheet of paper, and consequently, in most cases, on a small scale. This, in afterwards making the drawings, is, as may be necessary, increased in size. The three parts being drawn under one another, as shown in *fig.* 895*a*., wherein the middle diagram is the plan, the lower one the section, and the upper one the elevation. By thus beginning on a single sheet, in which the whole is before the eye, the corresponding lines are more readily transferred from one part to another. Having drawn through the middle of the paper the vertical AA, cut at right angles by the horizontal line BB, draw the required centres or axes of the walls CC and DD, and supposing the building is to be square, with the same opening of the compasses set out the axes of the return walls EE and FF. Having determined the thickness of the walls, one half may be set out on each side the axes, as in *ee*, *ff*, *cc*, and *dd*, and then the lines showing the thicknesses of the walls may be drawn. The width of openings in the walls may be next set out, half on each side the axes BB and AA, first drawn towards *bb* and *aa*, and the lines drawn to their places. Having thus proceeded, we shall discover that not only has the plan been drawn, but at the same time a considerable portion of the section and elevation. To distinguish the voids from the solids, the latter should be coloured or hatched, and then the next step will be as follows:— Parallel to the principal axis BB, draw the ground lines GG and GG. From these lines the heights of the building, its cornice and openings, may be set up in the section and elevation; and afterwards, the height of the roof and projection of the cornice having been determined, they may be set out and drawn. In the section, as in the plan, it is usual either to colour or hatch the solid parts, as we have done in the figure.

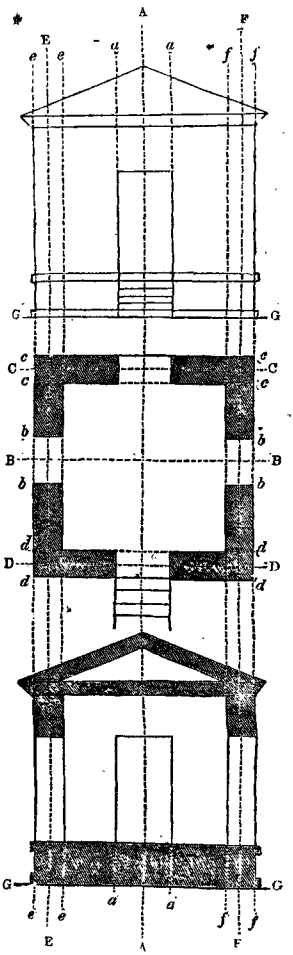

Fig. 859*a*.

2490*c*. Simple as the above process may be, it contains the whole elementary part of the mechanical process necessary for making a design. It might have been conducted on a more complicated mass, but had we done so, it would not have been so well understood, and we therefore deprecate any observations on the simpleness of our process by those who have been brought to know these things by practice and experience. We do not, however, feel we should discharge our duty before closing this section, without a censure on the attempt to convert drawings of *geometrical* elevations and sections into picturesque representations, because such practice is not only injurious to the art, but is dishonest, and has a tendency to mislead the architect's employer; and we are sorry to say that it is not unfrequently done with such a view. We denounce it, and without hesitation aver that the casting of shadows on a design is only admissible for the purpose of showing the relative depths of projecting parts; and when so admitted, the medium should be confined to Indian ink or sepia, and thrown in merely in masses, the apertures being just slightly filled in with the same colour.

Sect. VI.

WORKING DRAWINGS.

2491. Working drawings are those made of the parts at large for executing the works, which could not be well done from drawings on a small scale, wherein the small parts would not be either sufficiently defined, or could not be figured so as to enable the workman to set out his work with accuracy. They are generally in outline, except the sectional parts, which are frequently tinted to bring the profiles more readily before the eye.

2491*a*. It is obvious that though drawings made to a twelfth or a twenty-fourth part of their real size may well enough supply the wants of the workman where there is no complication in the distribution and arrangement, and where there is a simple treatment of regular forms, of right angles and the like; yet in all cases wherein we have to deal with the minor details of architecture, and in construction, where the variety of forms used is infinite from the variety of the circumstances, nothing short of drawings of the full, or at the least of half, the size will safely guide the workman.

2491*b*. The art of making working drawings, which must have been well understood at all periods of the practice of architecture, involves a thorough knowledge of projection, or descriptive geometry, and consists in expressing by lines all that occurs for the development of every part of the details of a building, in plan, elevation, and profile, each part being placed for the use of the workman with clearness and precision. All the rules by which working drawings are wrought are dependent on the matter in this work already communicated to the reader, excepting only those details of the orders, and some other matters, which will be found in Book III. But we shall here, nevertheless, briefly replace before him the leading principles whereon working drawings are to be prepared. And first, he is to recollect that solids are only represented by the faces opposite to the eye; secondly, that the surfaces by which solids are enclosed are of two sorts, that is, rectilinear or curvilinear. Those bodies in which these properties are combined may be divided into three sorts: 1. Those which are bounded by plane surfaces, such as prisms, pyramids, and generally all straight work. 2. Those in which there is a mixture of straight and curved lines, as cylinders, cones, or portions of them, voussoirs of vaulting, and the like; and 3. Those solids wherein a double flexure occurs, as in the sphere, spheroid, and in many cases of voussoirs.

2491*c*. We should, however, unnecessarily use our limited space by further entering on these matters, on which enough has been said in previous sections. The plain truth is, that working drawings are to be so made for the use of the artificer as to embody on a scale, to prevent any mistake, all the information which this work has already given on construction, and that which follows in the more refined view of architecture as a fine art.

2491*d*. In works whose magnitude is not of the first class, the drawing of every part, both in construction and in those which involve the work as one of art, should be given of the full size whereof it is proposed to be executed. Where the building is large, as also the parts, this may be dispensed with; but then it becomes (the detail being drawn on a smaller but fully intelligible scale) the duty of the architect to see that the drawings he furnishes are faithfully drawn out to the full size by the artificer on proper moulds. Often it is useful—never, indeed, otherwise—to *offer up*, as it is called, small portions of mouldings on the different parts of a building, to ascertain what the effect may be likely to be at the heights fixed for their real places. In these matters he should leave no means untried to satisfy himself of the effect which his first drawings *in small* is likely to produce when executed.

2491*e*. We have presumed that the architect is so far educated as to have acquired a full knowledge of all that rules can teach, and that, strictly speaking, he has proportioned his work in conformity with them. Still, in real practice, there are constantly so many circumstances which concur in making it almost necessary to depart from established rules, such as surrounding buildings, where it is of importance to give predominance to a part for the purpose of making it a feature, that the expedient of trying a portion of the proposed detail in the place it is actually to occupy, is a matter that we would advise every architect to adopt after he has made and studied the working drawings whereof we treat.

2491*f*. We have not alluded to the matters of carpentry and joinery, in which it is often necessary to give the artificer information by means of working drawings; but the methods of trussing in carpentry, and of framing in joinery, often require working drawings. What has already been exhibited under those heads (2031, *et seq.*) will prevent his being left uninstructed, and will, moreover, have afforded such information as to prepare him, by the exercise of his own ingenuity, for such cases as may not have been specially given in the examples herein contained. We therefore here close our observations under this section by an intimation to the student, that the proper preparation of working drawings for the use of the artificer tests his acquaintance with the theory and practice of the art, and is of the utmost importance to the pocket of the employer, which it is his duty as a gentleman incessantly to protect.

BOOK III.

PRACTICE OF ARCHITECTURE.

CHAP. I.

GRECIAN AND ITALIAN ARCHITECTURE.

SECT. I.

BEAUTY IN ARCHITECTURE.

2492. THE existence of architecture as a fine art is dependent on *expression*, or the faculty of representing, by means of lines, words, or other media, the inventions which the architect conceives suitable to the end proposed. That *end* is twofold; to be useful, and to connect the use with a pleasurable sensation in the spectator of the invention. In eloquence and poetry the end is to instruct, and such is the object of the higher and historical classes of painting; but architecture, though the elder of the arts, cannot claim the rank due to painting and poetry, albeit its end is so much more useful and necessary to mankind. In the sciences the end is utility and instruction, but in them the latter is not of that high moral importance, however useful, which allows them for a moment to come into competition with the great arts of painting, poetry, and eloquence. It will be seen that we here make no allusion to the lower branches of portrait and landscape painting, but to that great moral and religious end which fired the mind of Michael Angelo in the Sistine Chapel, and of Raffaelle Sanzio in the Stanze of the Vatican and in the Cartoons. Above the lower branches of painting just mentioned, the art whereof we treat occupies an exalted station. In it though the chief end is to produce an useful result, yet the expression on which it depends, in common with the other great arts, brings each within the scope of those laws which govern generally the fine arts whose object is beauty. Beauty, whatever difference of opinion may exist on the means necessary to produce it, is by all admitted to be the result of every perfection whereof an object is susceptible, such perfections being altogether dependent on the agreeable proportions subsistent between the several parts, and those between the several parts and the whole. The power or faculty of inventing is called *genius*. By it the mind is capable of conceiving and of expressing its conceptions. *Taste*, which is capable of being acquired, is the natural sensation of a mind refined by art. It guides genius in discerning, embracing, and producing beauty. Here we may for a moment pause to inquire what may be considered a standard of taste, and that cannot be better done than in the words used on the subject by Hume (Essay xxiii.): "The great variety of tastes," says that author, "as well as of opinion, which prevails in the world, is too obvious not to have fallen under every one's observation. Men of the most confined knowledge are able to remark a difference of taste in the narrow circle of their acquaintance, even where the persons have been educated under the same government and have early imbibed the same prejudices. But those who can enlarge their view to contemplate distant nations and remote ages are still more surprised at the great inconsistence and contrariety. We are apt to call *barbarous* whatever departs widely from our own taste and apprehension, but soon find the epithet of reproach retorted on us, and the highest arrogance and self-conceit is at last startled on observing an equal assurance on all sides, and scruples, amidst such a contest of sentiment, to pronounce positively in its own favour." True as are the observations of this philosopher in respect of a standard of taste, we shall nevertheless attempt to guide the reader to some notion of a standard of taste in architecture.

2493. There has lately grown into use in the arts a silly pedantic term under the name of Æsthetics, founded on the Greek word Αἰσθητικὸς, one which means having the power of perception by means of the senses; said to be the science whereby the first principles in all the arts are derived, from the effect which certain combinations have on the mind as connected with nature and reason: it is, however, one of the metaphysical and useless additions

to nomenclature in the arts, in which the German writers abound, and in its application to architecture of least value; because in that art form is from construction so limited by necessity, that sentiment can scarcely be said to be further connected with the art than is necessary for keeping the subordinate parts of the same character as the greater ones under which they are combined; and, further, for thereby avoiding incongruities.

2494. It is well known that all art in relation to nature is subject to those laws by which nature herself is governed, and if we were certain that those rules of art which resulted from reason were necessarily and actually connected with sensation, there would be no difficulty in framing a code of laws whereon the principles of any art might be firmly founded. "Principles in art," as well defined by Payne Knight, "are no other than the trains of ideas which arise in the mind of the artist out of a just and adequate consideration of all those local, temporary, or accidental circumstances upon which their propriety or impropriety, their congruity or incongruity, wholly depend." By way of illustrating the observation just made, we will merely allude to that maxim in architecture which inculcates the propriety of placing openings over openings and piers over piers, disallowing, in other words, the placing a pier over an opening without the exhibition of such preparation below as shall satisfy the mind that security has been consulted. There can be no doubt that a departure from the maxim creates an unpleasant sensation in the mind, which would seem to be immediately and intimately connected with the laws of reason; but there is great difficulty in satisfying one's self of the precise manner in which this operates on the mind, without a recurrence to the primitive types in architecture, and thence pursuing the inquiry. But in the other arts the types are found in nature herself, and hence in them no difficulty occurs in the establishment of laws, because we have that same nature whereto reference may be made. We shall have to return to this subject in the section on the Orders of Architecture, to which we must refer the reader, instead of pursuing the subject here.

2495. Throughout nature beauty seems to follow the adoption of forms suitable to the expression of the end. In the human form there is no part, considered in respect to the end for which it was formed by the great Creator, that in the eye of the artist, or rather, in this case the better judge, the anatomist, is not admirably calculated for the function it has to discharge; and without the accurate representation of those parts in discharge of their several functions, no artist by means of mere expression, in the ordinary meaning of that word, can hope for celebrity. This arises from an inadequate representation having the appearance of incompetency to discharge the given functions; or, in other words, they appear unfit to answer the end.

2496. We are thus led to the consideration of *fitness*, which, after all, will be found to be the basis of all *proportion*, if not proportion itself. Alison, in his *Essay on Taste*, says, "I apprehend that the beauty of proportion in forms is to be ascribed to this cause," (fitness) "and that certain proportions affect us with the emotion of beauty, not from any original capacity in such qualities to excite this emotion, but from their being expressive to us of the fitness of the parts to the end designed." Hogarth, who well understood the subject, concurs with Alison in considering that the emotion of pleasure which proportion affords does not resemble the pleasure of sensation, but rather that feeling of satisfaction arising from means properly adapted to their end. In his *Analysis of Beauty* that great painter places the question in its best and truest light, when, speaking of chairs and tables, or other common objects of furniture, he considers them merely as fitted from their proportions to the end they have to serve. In the same manner, says Alison, "the effect of disproportion seems to me to bear no resemblance to that immediate painful sensation which we feel from any disagreeable sound or smell, but to resemble that kind of dissatisfaction which we feel when means are unfitted to their end. Thus the disproportion of a chair or table does not affect us with a simple sensation of pain, but with a very observable emotion of dissatisfaction or discontent, from the unsuitableness of their construction for the purposes the objects are intended to serve. Of the truth of this every man must judge from his own experience." We cannot refrain from continuing our extracts from this most intelligent author. "The habit," he says, "which we have in a great many familiar cases of immediately conceiving this fitness from the mere appearance of the form, leads us to imagine, as it is expressed in common language, that we determine proportion by the eye, and this quality of fitness is so immediately expressed by the material form, that we are sensible of little difference between such judgments and a mere determination of sense; yet every man must have observed that in those cases where either the object is not familiar to us or the construction intricate our judgment is by no means speedy, and that we never discover the proportion until we previously discover the principle of the machine or the means by which the end is produced."

2497. The nature of the terms in which we converse shows the dependence of proportion on fitness, for it is the sign of the quality. The natural answer of a person asked why the proportion of any building or machine pleased him, would be, because the object by such proportion was fit or proper for its end. Indeed, proportion is but a synonyme of fitness,

for if the form be well contrived, and the several parts be properly adjusted to their end, we immediately express our opinion that it is well proportioned.

2498. There is, however, between proportion and fitness, a distinction drawn by our author, which must be noticed. "Fitness expresses the relation of the whole of the means to the end; proportion, the proper relation of a part or parts to their end." But the distinction is too refined to be of importance in our consideration; for the due proportion of parts is simply that particular form and dimension which from experience has been found best suited to the object in view. "Proportion," therefore continues Alison, "is to be considered as applicable only to forms composed of parts, and to express the relation of propriety between any part or parts and the end they are destined to serve."

2499. Forms are susceptible of many divisions, and consequently proportions; but these are only subordinate to the great end of the whole. Thus, for instance, in the constantly varying forms of fashion, say in a chair or table, the merely ornamental parts may bear no relation to the general fitness of the form, but they must be so contrived as to avoid unpleasant sensation, and not to interfere with the general fitness. If we do not understand the nature of its fitness, we cannot judge of the proportion properly. "No man," says Alison, "ever presumes to speak of the proportions of a machine of the use of which he is ignorant." When, however, we become acquainted with the use or purpose of a particular class of forms, we at the same time acquire a knowledge which brings under our view and acquaintance a larger circle of agreeable proportions than the rest of the world understand; and those parts which by others are regarded with indifference, we contemplate with pleasure, from our superior knowledge of their fitness for the end designed. The proportions of an object must not in strength be carried beyond what is required for fitness, for in that case they will degenerate into clumsiness, whilst elegance, on the contrary, is the result of the nicest adjustment of proportion.

Fig. 860.

2500. Fitness cannot exist in any architectural object without *equilibrium* in all the parts as well as the whole. The most complete and perfect notion that can be conceived of *stability*, which is the result of equilibrium, may be derived from the contemplation of an horizontal straight line; whilst, on the contrary, of instability nothing seems more expressive than a vertical straight line. These being, then, assumed as the extremes of stability and instability, by carrying out the gradations between the two extremes, we may, extending in two parts the vertical line, obtain various forms, more or less expressive of stability as they approach or recede from the horizontal line. In *fig.* 860. we have, standing on the same base, the general form of the lofty Gothic spire; the pleasing, solid, and enduring form of the Egyptian pyramid; and that of the flat Grecian pediment: which last, though in its inclination adjusted on different grounds, which have been examined in Book II. Chap. III. subsect. 2027, *et seq.*, is an eminent instance of stability. The spire, from its height and small base, seems to possess but a tottering equilibrium compared with the others.

2501. Stability is obviously dependent on the laws of gravitation, on which, under the division of statics, not only the architect, but the painter and sculptor, should bestow considerable attention. We cannot for a moment suppose it will be disputed that at least one of the causes of the beauty of the pyramid is a satisfactory impression on the mind of the state of rest or stability it possesses. Rest, repose, stability, balance, all meaning nearly the same thing, are then the very essential ingredients in fitness; and therefore, in architectural subjects, instability, or the appearance of it, is fatal to beauty. Illustrations of this exist in the famous Asinelli and Garisendi towers at Bologna, and at Pisa in the celebrated leaning Campanile.

2502. It may be objected to what we have written, that fitness alone will not account for the pleasure which arises in the contemplation of what are called the orders of architecture, and Alison seems very much to doubt whether there be not some other cause of beauty. It will, however, be our business to show how the ancients, their inventors, considered principally their fitness; and upon these grounds to show, moreover, how the proportions in ancient examples varied, and may be still further varied, without infringing upon the principles which guided them in the original invention. Payne Knight has well observed, "that the fundamental error of imitators in all the arts is, that they servilely copy the effects which they see produced, instead of supplying and adopting the principles which guided the original artists in producing them; wherefore they disregard all those local, temporary, or accidental circumstances upon which their propriety or impropriety, their congruity or incongruity, wholly depend." "Grecian temples, Gothic abbeys, and feudal castles were all well adapted to their respective uses, circumstances, and situations: the distribution of the parts subservient to the purposes of the whole; and the ornaments and decorations suited to the character of the parts, and to the manners, habits, and employments of the persons who were to occupy them: but the house of an English noble-

man of the 18th or 19th century is neither a Grecian temple, a Gothic abbey, nor a feudal castle; and if the style of distribution or decoration of either be employed in it, such changes and modifications should be admitted as may adapt it to existing circumstances, otherwise the scale of its exactitude becomes that of its incongruity, and the deviation from principle proportioned to the fidelity of imitation." This is but another application of the principle of fitness which we have above considered, the chief foundation of beauty in the art. We have shown how it is dependent on stability as a main source of fitness, and here subjoin some maxims which will lead the student to fitness in his designs, and prevent him from running astray, if he but bring himself to the belief that they are reasonable, and founded upon incontestable grounds, which we can assure him they are.

First. Let that which is the stronger part always bear the weaker.
Second. Let solidity be always real, and not brought to appear so by artifice.
Third. Let nothing be introduced into a composition whose presence is not justified by necessity.
Fourth. Let unity and variety be so used as not to destroy each other.
Fifth. Let nothing be introduced that is not subordinate to the whole.
Sixth. Let symmetry and regularity so reign as to combine with order and solidity.
Seventh. Let the proportions be of the simplest sort.
Eighth. Let him recollect that nothing is beautiful which has not some good and useful end.

If, after having made his design, he will scrupulously test it by these maxims *seriatim*, and will strike out what is discordant with the tenor of them, he will have overcome a few of the difficulties which attend the commencement of his career.

2503. We are not of the same opinion with those who, on a geometrical elevation of a building, draw lines from its apex, which, bounding the principal parts of the outline, find a pyramidal form, and thence infer beauty of general outline. If those who favour such a notion will but reflect for a moment, they must see that this cannot be a test of its effect, inasmuch as the construction of a geometrical elevation of any edifice supposes it to be viewed at an infinite distance, whereas, in fact, it is most generally viewed under angles which would puzzle the most learned architect, without full investigation, to discover the primary lines which they assume to be the causes of its beauty. The obscurations and foreshortenings that take place are at points of view near the building itself; and, however judicious it may be to form the general masses in obedience to such a system, so as to produce an effect in the distance that may be in accordance with the principle, it would be extremely dangerous to lay the principle down as a law. The finest view of St. Paul's is perhaps a little east of Fetter Lane, on the northern side of Fleet Street; but it would puzzle any one to discover its pyramidal form from that point of view.

2504. The beauty of the proportions of architecture in the interiors of buildings is dependent on those which govern the exteriors. Much has been said on proportions of rooms, which, hereafter, we shall have to notice: we mean the proportions of their length to their breadth and height. That these are important, we cannot deny; but whether the beauty of a room is altogether dependent on the due adjustment of these, we have some doubts; that is, under certain limits. We here address ourselves more particularly to that fitness which, in ornamenting a ceiling, for example, requires that the beams which appear below the general surface should invariably fall over piers, and that in this respect corresponding sides should be uniform. In the study of this point, Inigo Jones is the great English master who has left the student the most valuable examples of this branch of the art.

2505. It may, perhaps, be useful to observe generally that the bare proportions of the interiors of apartments depend on the purposes for which they are intended, and according to these we seek immediately for the expression of their fitness. This point, therefore, involves on the part of the architect so general an acquaintance with the most refined habits of his employers, that we should be almost inclined to agree with Vitruvius on the multifarious qualifications necessary to constitute a good one. Certain it is that no instructions he can receive for building a mansion will qualify him without an intimate acquaintance with the habits of the upper classes of society.

2506. We have already stated that it is hopeless to arrive at a fixed standard of taste. That considered worthy of the appellation will not be so considered in another. "The sable Africans," says Knight, quoting from Mungo Park, "view with pity and contempt the marked deformity of the Europeans, whose mouths are compressed, their noses pinched, their cheeks shrunk, their hair rendered lank and flimsy, their bodies lengthened and emaciated, and their skins unnaturally bleached by shade and seclusion, and the baneful influence of a humid climate." In the countries of Europe, where some similarity of taste may be expected, the tyranny of fashion, no less than that of habit and circumstance, has, and always will have, its influence on the arts. Within the short space of even a few months we have seen what is called the *renaissance* style of architecture imported from France, drawing into its vortex all classes of persons, many of them among the higher

ranks, possessed of education to have patronised better taste; and in architecture, and some other arts, no one solves the question of what is really right by saying that there have been errors in the tastes of different ages.

2507. The specimens of Greek sculpture, whose beauty is founded in nature herself, will throughout all time excite the admiration of the world; because in this case, the standard or type being nature, mankind generally may be supposed to be competent judges of the productions of the art. But it is very different in architecture, whose types in every style are, as respects their origin, uncertain; and when we are asked whether there be a real and permanent principle of beauty in the art, though we must immediately reply in the affirmative, we are at the same time constrained to refer it to the quality of fitness. If this were not the case, how could we extend our admiration to the various styles of Egyptian, Grecian, Roman, Gothic, and Italian architecture? These at first appear, compared with each other, so dissimilar, that it seems impossible to assign beauty to one without denying it to the rest. But on examination each will be found so fitted to its end, that such cause alone will be found to be the principal source of the pleasure that an educated mind receives from each style; and that thence it arises, rather than from any certain or definable combinations of forms, lines, or colours that are in themselves gratifying to the mind or agreeable to the organs of sensation. If this be true, what becomes of the doctrine of the German æsthetical school, so vaunted of by self-constituted critics and reviewers, who pass their judgment *ex cathedrâ* on works they have never seen, and, strange to say, are tolerated for a moment by the public? The truth is, the public rarely give themselves the trouble to judge; and unless led, which is easily done by the few, do not undertake the trouble of judging for themselves. That the Egyptian pyramid, the Grecian and the Roman temple, the early Christian basilica, the Gothic cathedral, the Florentine palace, the Saracenic mosque, the pagoda of the East, are all beautiful objects, we apprehend none will dispute; but there is in none of them a common form or standard by which we can judge of their beauty: the only standard on which we can fall back is the great fitness of them, under their several circumstances, for the end proposed in their erection.

2508. We are thus unavoidably driven to the conclusion that beauty in its application to architecture changes the meaning of the word with every change of its application; for those forms which in one style are strictly beautiful on account of their fitness, applied to another become disgusting and absurd. By way of illustrating this, let us only picture to ourselves a frieze of Grecian triglyphs separating the nave and clerestory of a Gothic cathedral. From what we have been taught to consider the type of the Doric frieze connected with its triglyphs an idea of fitness immediately arises in the mind; but we cannot trace its fitness in a dissimilar situation, neither can we comment on such an incongruity better than in the oft-quoted lines of Horace: —

> "Humano capiti cervicem pictor equinam
> Jungere si velit, et varias inducere plumas
> Undique collatis membris, ut turpiter atrum
> Desinet in piscem mulier formosa supernè;
> Spectatum admissi risum teneatis amici?"

The influence of circumstances in every age has imparted to each style of architecture its peculiar beauty and interest; and until some extraordinary convulsion in society give the impetus to a new one, we are constrained to follow systems which deprive us of other novelty than those of changes which are within the spirit of the universally established laws of the art. Turn to the Gothic churches of the present day, — the little pets of the church commissioners and clergy. What objects of ineffable contempt the best of them are! The fact is, the religious circumstances of the country have so changed that they are wholly unsuitable in style to the Protestant worship. Had, with the scanty means afforded to the architects, such a model as St. Paul's, Covent Garden, been adopted, we might have seen a number of edifices in the country, though

> "Facies non omnibus una
> Nec diversa tamen,"

that might have been an honour to the age in which we live, and suitable to the circumstances of the times.

2509. Unity and harmony in a work necessarily enter into that which is beautiful; and it will not therefore require any argument to show that from a mixture of styles in any building incongruity and unfitness, and consequently a want of unity and harmony, must be the result. Hence we cannot agree with those wise reviewers who advocate the possibility of amalgamating the arch with the severe Grecian style. We leave them to their dreams, and trust that before we give them credence we may have some proof of their practical power in this respect.

2510. Symmetry is that quality which, as its name imports, from one part of an assemblage of parts enables us to arrive at a knowledge of the whole. It is a subordinate, but nevertheless a necessary, ingredient in beauty. It is necessary that parts performing the same office in a building should be strictly similar, or they would not *ex vi termini* be

symmetrical; so, when relations are strictly established between certain parts, making one the measure of another, a disregard of the symmetry thus induced cannot fail of destroying beauty. But here again we have to say, that for want of attention to the similarity of the parts, or neglect of the established relations on which the whole is founded, they have lost their symmetry, and have thus become *unfit* for their purpose; so that thus again we return to fitness as the main foundation of beauty.

2511. Colour abstractedly considered has little to do with architectural beauty, which is founded, as is sculpture, on fine form. We are here speaking generally, and are not inclined to assert that the colour of a building in a landscape is unimportant to the general effect of that landscape, or that the colours used on the walls of the interior of a building are unessential considerations; but we do not hesitate to say that they are of minor consequence in relation to our art. We believe it would be difficult to paint (we mean not in the sense of the artist) the interior of the banqueting room at Whitehall, were it restored to its original destination, and divested of the ruinous accessories which from its original purpose have turned it from a banqueting room into a chapel,—we believe, we say, that it would be difficult to paint it so as to destroy its internal beauty. But as we intend to be short under this head, we shall quote a brochure touching on this subject published by us in 1837.

2512. One of the beauties tending to give effect to the edifices of Greece has been, on the testimony of almost all travellers, the colour of the materials whereof they are composed. Dr. Clarke observes that a warm ochreous tint is diffused over all the buildings of the Acropolis, which *he* says is peculiar to the ruins of Athens. "Perhaps," says the author, "to this warm colour, so remarkably characterising the remains of ancient buildings at Athens, Plutarch alluded" (*In Vita Pericles*) "in that beautiful passage cited by Chandler, where he affirmed *that the structures of Pericles possessed a peculiar and unparalleled excellence of character; a certain freshness bloomed upon them and preserved their faces uninjured, as if they possessed a never-fading spirit, and had a soul insensible to age.*" It is singular that recent discoveries have incontestably proved that this species of beauty at all events did not originally exist in them, inasmuch as it is now clearly ascertained that it was the practice of the Greeks to paint the whole of the inside and outside of their temples in party colours. It had been some time known that they were in the habit of painting and picking out the ornaments on particular parts of their buildings; but M. Schaubert, the architect of the King of Greece, found on examination that this fell far short of the extent to which this species of painting was carried, and M. Semper, another German architect, has fully corroborated the fact in his examination of the Temple of Theseus. The practice was doubtless imported into Greece from Egypt, and was not to be easily abandoned, seeing the difficulty of falling away from the habits of a people whence it seems certain the arts of Greece more immediately came. It is by no means uncommon for a person to be fully alive to all the beauties of form, without at the same time having a due feeling or perception of the beauty resulting from harmony in colouring. It is therefore not to be assumed that the Greeks, though given to a practice which we would now discourage, possessed not that taste in other respects which has worthily received the admiration of posterity. The practice of painting the inside and outside of buildings has received the name of *polychromatic* architecture, and we shall here leave it to the consideration of the student as a curious and interesting circumstance, but certainly without a belief that it could add a charm to the stupendous simplicity and beauty of such a building as the Parthenon.

2513. After all that we have said of fitness, it will be expected that in *decoration* it shall form a principal ingredient. By the term decoration we understand the combination of objects and ornaments that the necessity of variety introduces under various forms, to embellish, to enrich, and to explain the subjects whereon they are employed. The art of decoration, so as to add to the beauty of an object, is, in other words, that of carrying out the emotions already produced by the general form and parts of the object itself. By its means the several relations of the whole and the parts to each other are increased by new combinations; new images are presented to the mind whose effect is variety, one great source of pleasure. From these observations two general rules may be deduced in respect of decoration. *First*, that it must actually be or seem to be necessary. *Second*, that such objects must be employed in it as have relation to the end of the general object of the design. We are not to suppose that all parts of a work are susceptible of ornament. Taste must be our guide in ascertaining where decoration is wanted, as well as the quantity requisite. The absence of it altogether is in many cases a mode of decoration. As in language its richness and the luxuriance of images do not suit all subjects, and simplicity in such cases is the best dress, so in the arts of design many subjects would be rather impoverished than enriched by decoration. We must therefore take into consideration the character of the building to be decorated, and then only apply such ornament as is necessary and suitable to that character. We may judge of its necessity if the absence of it causes a dissatisfaction from the void space left; of its suitableness, by its developing the character. History has recorded the contempt with which that decorator was treated who

ornamented the senate house with statues of wrestlers, and the gymnasium with statues of senators.

2514. By some the art of architecture itself has been considered nothing more than that of decorating the buildings which protection from the elements induces us to raise.

2515. The objects which architecture admits for decoration result from the desire of producing *variety*, *analogy*, and *allegory*. We here follow Quatremère de Quincy. (*Encyc. Method.*) The first seems more general than the others, as being common among all nations that practise building. It is from this source we have such a multitude of cut-work, embroidery, details, compartments, and colours, more or less minute, which are found in every species of architecture. It would be useless for the most philosophical mind to seek for the origin of these objects in any want arising out of the mere construction, or in any political or superstitious custom. Systems of conjecture might be exhausted without arriving one point nearer the truth. Even in the most systematic of the different kinds of architecture, namely, that of the Greeks, we cannot avoid perceiving a great number of forms and details whose origin is derived from the love of variety, and that alone. In a certain point of view, thus considered, an edifice is nothing more than a piece of furniture, a vase, an utensil, the ornaments on which are placed more for the purpose of pleasing the eye than any other. Such, for instance, are the roses of caissons in ceilings and sofites, the leaves round the bell of the Corinthian capital, the Ionic volutes, and many others, besides universally the carving of mouldings themselves. These ornaments, drawn from the store-house of nature, are on that account in themselves beautiful; but it is their transference to architecture, which in the nature of things can have but a problematical and conjectural origin, that seems to indicate a desire to vary the surface. Unless it was the desire of variety that induced them, we know not what could have done so.

2516. It has been well observed by the author we have just quoted, that though the art has been obliged to acknowledge that many of its decorations depend in their application on such forms as necessity imposes, and in the formation of them on chance, caprice, or whatever the love of variety may dictate, yet in the disposition of them there must reign an order and arrangement subordinate to that caprice, and that at this point commences the difference between architecture as an art subservient to laws which are merely dependent on the pleasure imparted to the eye, and those which depend on the mere mechanical disposition of the building considered as a piece of furniture. Architecture, of all the arts, is that which produces the fewest emotions of the minds of the many, because it is the least comprehensible in regard to the causes of its beauty. Its images act indirectly on our senses, and the impressions it seems to make appear reducible chiefly to magnitude, harmony, and variety, which after all are not qualities out of the reach of an architect of the most ordinary mind, and therefore not — at least the first and last — unattainable where economy does not interfere to prevent the result to be attained.

2517. Analogy, the second of the objects by which decoration is admitted into architecture, seems to be resultant from the limited nature of all human inventions in the arts, and the power of being unable to invent except by imitation and alteration of the forms of objects pre-existent. It is most difficult to discard altogether what have been considered types in architecture, and that difficulty has so prevailed as to limit those types to their most probable origin in the case of the orders.

2518. The reader will begin to perceive that our analogy in decoration tends upon trees for columns, the ends of beams for triglyphs, and the like. Whatever truth there may be in this analogy, it is now so established as to guide the rules of decoration that are involved in it; and it must be conceded, that if we are desirous of imitating the peculiar art of any country, we have no hope of success but by following the forms which the construction in such country engenders; and we must admit that, as far as external circumstances can direct us, the architecture of Greece, which, modified, has become that of the whole of Europe, and will become that of America, seems so founded on the nature of things, that, however we may doubt, it would not be prudent to lead the reader away from the consideration, and perhaps from a belief, that such is the truth. Without holding ourselves bound by the analogy of the types of the tree and the cross beam, which appear to have guided the architects of Greece, we can without hesitation assert, that whenever those have been abandoned the art has fallen on the most flagrant vices; witness the horrors of the school of Borromini, where the beams are broken, pediments, which are the gables of roofs, are broken into fantastic forms, and none of the parts seem naturally connected with each other. The works of the school in question seem indeed so broken up, that the study of them would almost convince an impartial and competent judge that the converse of its practice is sufficiently beautiful to establish the truth of the types whereon we have here and before expressed our scepticism. "Sitôt," says De Quincy, "que le génie decorateur s'est cru libre des entraves de l'analogie, toutes les formes caractéristiques se sont contournées, perverteés, et dénaturées, au point qu'il y a entr'elles et celle de la bonne architecture, plus de distance qu'entre celles-ci et les types de la primitive construction."

2519. In the decoration of architecture, neither of the other two means employed are

more important than that ocular language which architecture occasionally employs in its ornaments. By its use architecture is almost converted into painting, and an edifice becomes a picture, or a collection of pictures, through the aid of the sculptor. We shall refer to no other building than the Parthenon to prove the assertion. Here the history of the goddess is embodied in the forms of the building, and to the decoration thus introduced the subordinate parts of the sculpture, if it be not heresy so to call them, is kept so under that we are almost inclined to cry out against their not having been principals instead of accessories. This is the true principle upon which buildings should be decorated to impress the mind of the spectator with the notion of beauty, and the principle which, carried out, no matter what the style be, will insure the architect his most ample reward, reputation. The matter that is supplied by allegory for decoration in architecture may be considered under three heads — *attributes*, *figures*, and *paintings*.

2520. The first takes in all those foliages, plants, flowers, and fruits, which from their constant use in sacrifices were at last transferred from the altar to the walls of the temple. The garlands, festoons, chaplets, and crowns which we find sculptured on temples seem to have had their origin from the religious ceremonies performed in them; as do the instruments of sacrifice, vases, the heads of the victims, pateræ, and all the other objects employed in the worship of the ancients. Thus, in architecture, these have become conventional signs, indicating the destination of the buildings to which they are applied. From the particular application of some ornaments on temples we derive in the end a language in the arts of imitation. It was thus that the eagle grasping in his talons the attribute of Jupiter, came to represent eternity and omnipotence; the myrtle and dove of Venus, the passion of love; the lyre and laurel of Apollo, to point to harmony and glory; the spear and helmet of Mars, to represent war. Palms and crowns became the emblems of victory, as did the olive the emblem of peace. In the same way the ears of corn of Ceres, the serpent of Esculapius, the bird of Minerva, and the cock of Mercury were equivalent to the expression of abundance, science, and vigilance. Instruments of the arts, sciences, in short, all objects useful to the end for which an edifice is erected, naturally become signs of that edifice; but applied otherwise become absurd. What, for instance, could be more ridiculous than placing ox sculls and festoons on the frieze of a Protestant church? — and yet this has been done in our own days.

2521. Figures of men and animals come under the second head. The application of these may be seen to their highest perfection in the Parthenon, to which we have already alluded. They may be introduced in low, high, or full relief. In the last case their situation is usually that of a niche. We shall say no more on the subject of figures than that of course they must have relation to the end for which the edifice is erected, and if not in that respect perfectly intelligible are worse than useless.

2522. The walls of Pompeii furnish ancient examples of the decoration obtained by the aid of painting, as do the loggie of the Vatican and the ceilings of the Farnesina modern examples of it. Herein the moderns have far surpassed anything we know of the ancient application of painting. Sculpture, however, seems more naturally allied to architecture than painting, and, except in purely decorative painting on walls and ceilings, the introduction of it seems bounded within narrow limits. The rules as to fitness of the subjects introduced, applicable to the first two heads, are equally so under that of painting.

Sect. II.

THE ORDERS.

2523. An order in architecture is a certain assemblage of parts subject to uniform established proportions, regulated by the office that each part has to perform. It may be compared to what organisation is in animal nature. As from the paw of a lion his dimensions may be deduced, so from a triglyph may be found the other parts of an example of the Doric order, and from given parts in other orders the whole configuration may be found. As the genus may be defined as consisting of *essential* and *subservient* parts, the first-named are the column and its entablature, which, as its name imports, is as it were the tabled work standing on the column. The subservient parts are the mouldings and detail into which the essential parts are subdivided, and which we shall hereafter separately consider. The species of orders are five in number, Tuscan, Doric, Ionic, Corinthian, and Composite, each of whose mass and ornaments are suited to its character and the expression it is intended to possess. These are the five orders of architecture, in the proper understanding and application whereof is laid the foundation of architecture as an art. The characters of strength, grace, and elegance, of lightness and of richness, are distinguishing features of the several orders, in which those characters ought to be found not only in the column employed, but should pervade the whole composition, whereof the

column is, as it were, the regulator. The mode of setting up, or, as it is technically termed, profiling an order, will be given in a subsequent part of this section. Here we shall merely observe that the entablature is subdivided into an architrave, which lies immediately upon the column, a frieze lying on the architrave, and a cornice, which is its uppermost subdivision. The height of these subdivisions together, that is, the whole height of the entablature, is one fourth that of the column according to the practice of the ancients, who in all sorts of entablatures seldom varied from that measure either in excess or defect. "Palladio, Scamozzi, Alberti, Barbaro, Cataneo, Delorme, and others," says Sir William Chambers, "of the modern architects, have made their entablatures much lower in the Ionic, Composite, and Corinthian orders than in the Tuscan or Doric. This, on some occasions, may not only be excusable but highly proper; particularly where the intercolumniations are wide, as in a second or third order, in private houses, or inside decorations, where lightness should be preferred to dignity, and where expense, with every impediment to the conveniency of the fabric, are carefully to be avoided; but to set entirely aside a proportion which seems to have had the general approbation of the ancient artists is surely presuming too far."

2524. As rules in the fine arts which have obtained almost universal adoption are founded on nature or on reason, we may be pretty certain that they are not altogether empirical, albeit their origin may not be immediately apparent. The grounds on which such rules are founded will, however, in most cases become known by tracing them to first principles, which we shall here endeavour to do in respect of this very important relation of height between the column and its entablature. We were first led into this investigation by the perusal of a work by M. Lebrun, entitled *Théorie de l'Architecture Grecque et Romaine deduite de l'analyse des Monumens antiques*, fol. Paris, 1807; but our results differ very widely from those of Lebrun, as will be seen on reference to that work.

2525. One of the most obvious principles of proportion in respect of loads and supports, and one seemingly founded on nature herself, is, that a support should not be loaded with a greater mass or load than itself; or, in other words, that there should be an equality between weights and supports, or, in the case in point, between the columns and entablature. In respect of the proportion of the voids below the entablature between the columns or supports, a great diversity of practice seems to have prevailed, inasmuch as we find them varying from 1·03 to 2·18, unity being the measure of the supports. Lebrun makes the areas of the supports, weights, and voids equal to one another, and in what may be termed the monumental examples of the Doric order, such as the Parthenon, &c., he seems borne out in the law he endeavours to establish; but in lighter examples, such as the temple (Ionic) of Bacchus at Teos, where the supports are to the voids as 1 : 2·05, and in the temple of Minerva Polias, where the ratio is as 1 : 2·18, he is beyond all question incorrect: indeed there hardly seems a necessity for the limitation of the voids he prescribes, seeing that, without relation separately to the weight and support, stability would be obtained so long as the centre of gravity of the load fell within the external face of the support. If it be admitted that, as in the two examples above mentioned, the voids should be equal to the supports jointly, we have a key to the rule, and instead of being surprised at the apparently strange law of making the entablature one fourth of the height of the column, we shall find that no other than the result assumed can flow from the investigation.

2526. In fig. 861. let AB be the height of the column, and let the distance between the columns be one third of the height of the column = CD. Now if AB be subdivided into four equal parts at *a*, *b*, and *c*, and the horizontal lines *ad*, *be*, and *cf* be drawn; also, if CD be divided horizontally into four equal parts, and lines be drawn perpendicularly upwards intersecting the former ones, the void will be divided into sixteen equal parallelograms, one half whereof are to be the measure of the two whole supports BC and DE; and DE being then made equal to one half of CD, it will be manifest, from inspection, that the two semi-supports will jointly be equal to eight of the parallelograms above mentioned, or one half of the void. We have now to place the entablature or weight AGHI upon the supports or columns, and equal to them in mass. Set up from A to F another row of parallelograms, each equal to those above mentioned, shown on the figure by AFKI. These will not be equal to the supports by two whole parallelograms, being in number only six instead of eight; dividing, therefore, 8, the number in the supports, by 6, the number already obtained, we have 1·333, &c., which is the height to be assigned to AG, so that the weight may exactly equal the supports, thus exceeding one quarter of the height of the support (or column) by $\frac{333}{1000}$ of such quarter, a coincidence sufficient to corroborate the reason on which the law is founded.

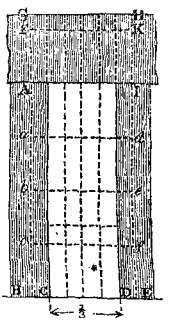

Fig. 861.

2527. From an inspection of the *figs.* 861, 862, 863, it appears that when the void is one third the height of the supports in width, the supports will be 6 diameters in height; when one fourth of their height, they will be 8 diameters high; also that the intercolumniation, called systylos or of two diameters, is constant by the arrangement. When the surface of the columns, as they appear to the eye, is equal to that of the entablature, and the voids are equal to the sum of those surfaces, the height of the entablature will always be one third of that of the columns. Thus, let the diameter of the columns be $=1$, their height $=h$, their number $=n$. Then the surface of the columns is nh; that of the entablature the same. As the surface of the voids is double that of the columns, the width of the intercolumniations is double the width of the columns, that is, $2n$ diameters, which, added to the n diameters of the columns, gives $3n$ diameters for length of the entablature; therefore, the surface of this entablature is nh, and its length being $3n$, its height must be $\frac{nh}{3n}=\frac{h}{3}$ exactly.

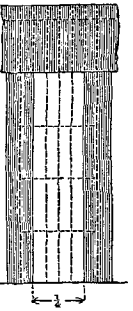

Fig. 862.

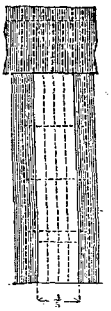

Fig. 863.

2528. Trying the principle in another manner, let *fig.* 864. be the general form of a tetrastyle temple wherein the columns are assumed at pleasure 8 diameters in height.

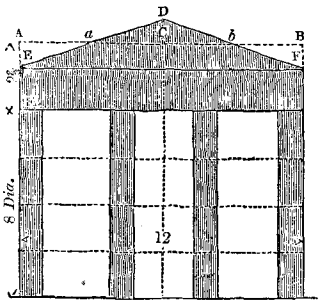

Fig. 864.

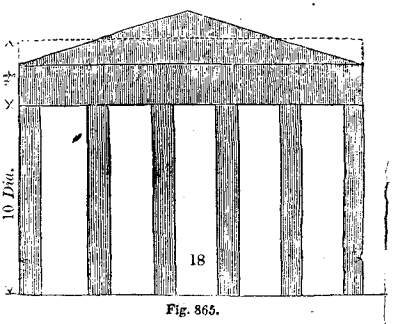

Fig. 865.

Then $4 \times 8 = 32$ the areas of the supports; and as to fulfil the conditions the three voids are equal to twice that area, or 64, they must consequently be in the aggregate equal to 8 diameters, for $\frac{64}{8}=8$, and the whole extent will therefore be equal to 12 diameters of a support or column. To obtain the height of the entablature so that its mass may equal that of the supports, as the measures are in diameters, we have only to divide 32, the columns, by 12, the whole extent of the facade, and we obtain two diameters and two thirds of a diameter for the height of the entablature, making it a little more than one quarter of the height of the column, and again nearly agreeing in terms of the diameter with many of the finest examples of antiquity. If a pediment be added, it is evident, the dotted lines AC, CB being bisected in *a* and *b* respectively, that the triangles AE*a*, *b*FB are respectively equal to CD*a* and D*b*C, and the loading or weight will not be changed.

2529. Similar results will be observed in fig. 865., where the height is ten diameters, the number of columns 6, the whole therefore 180, the supports being 60. Here $\frac{60}{18}=3\frac{1}{3}$ diameters will be the height of the entablature. This view of the law is further borne out by an analysis of the rules laid down by Vitruvius, book iii. chap. 2,; — rules which did not emanate from that author, but were the result of the practice of the time wherein he lived, and, within small fractions, strongly corroborative of the soundness of the hypothesis of the voids being equal to twice the supports. Speaking of the five species of temples, after specifying the different intercolumniations, and recommending the eustylos as the most beautiful, he thus directs the formation of temples with that interval between the columns. "The rule for designing them is as follows: — The extent of the front being given, it is, if tetrastylos, to be divided into $11\frac{1}{2}$ parts, not including the projections of the base and plinth at each end; if hexastylos, into 18 parts; if octastylos, into $24\frac{1}{2}$ parts. One of either of these parts, according to the case, whether tetrastylos, hexastylos, or octastylos, will be a measure equal to the diameter of one of the columns." . . . . "The heights of the columns will be $8\frac{1}{2}$ parts. Thus the intercolumniations and the heights of the columns will have proper proportion." In the same chapter he gives directions for setting out aræostyle, diastyle, and systyle temples. The tetrastylos, he states, is $11\frac{1}{2}$ parts wide and $8\frac{1}{2}$ high; the area therefore of the whole front becomes $11\frac{1}{2} \times 8\frac{1}{2} = 97\frac{3}{4}$.

The four columns are $4 \times 8\frac{1}{2} = 34$, or very little more than one third of the whole area; the remaining two thirds, speaking in round numbers, being given to the intercolumns or voids. The hexastylos (see *fig.* 865.) is 18 parts wide and $8\frac{1}{2}$ high; the whole area therefore is $18 \times 8\frac{1}{2} = 153$. The six columns are $6 \times 8\frac{1}{2} = 51$, or exactly one third of the whole area; the voids or intercolumns occupying the remaining two thirds. The octastylos is $24\frac{1}{2}$ parts wide and $8\frac{1}{2}$ high. Then $24\frac{1}{2} \times 8\frac{1}{2} = 208\frac{1}{4}$. The eight columns are $8 \times 8\frac{1}{2} = 68$, being a trifle less than one third of the area, and the voids or intercolumns about double, or the remaining two thirds. The average of the intercolumns in the first case will be $\frac{11\frac{1}{2}-4}{3} = 2\frac{1}{2}$ diameters. In the second case $\frac{18-6}{5} = 2\frac{2}{5}$ diameters. In the third case $\frac{24\frac{1}{2}-8}{7} = 2\frac{347}{1000}$ diameters.

2530. A discrepancy between practice and theory, unless extremely wide, must not be allowed to interfere with principles, and therefore no hesitation is felt in submitting a synoptical view of some of the most celebrated examples of antiquity in which a comparison is exhibited between the voids and supports; certain it is that in every case the former exceed the latter, and that in the earlier examples of the Doric order, the ratio between them nearly approached equality. In comparing, however, the supports with the weights, there is every appearance of that part of the theory being strictly true; for in taking a mean of the six examples of the Doric order, the supports are to the weights as 1 : 1·16; in the five of the Ionic order as 1 : 1·05; and in the four of the Corinthian order as 1 : 1·04, a coincidence so remarkable that it must be attributed to something more than accident, and deserves much more extended consideration than it has hitherto received.

Building.	Order.	Number of Columns.	Supports.	Weights.	Voids.
Temple of Jupiter Nemeus	Doric	6	1·00	0·79	1·03
Parthenon	—	8	1·00	1·07	1·04
Temple at Bassæ	—	6	1·00	1·14	1·16
Temple of Minerva at Sunium	—	6	1·00	1·40	1·17
Temple of Theseus at Athens	—	6	1·00	1·13	1·21
Temple of Jupiter Panhellenius	—	6	1·00	1·45	1·36
Temple of Erectheus	Ionic	6	1·00	0·89	1·24
Temple of Fortuna Virilis at Rome	—	4	1·00	1·15	1·71
Temple on the Ilyssus	—	4	1·00	0·96	1·72
Temple of Bacchus at Teos	—	8	1·00	1·35	2·05
Temple of Minerva Pollas, Athens	—	4	1·00	1·01	2·18
Portico of Septimius Severus	Corinthian.	6	1·00	0·93	1·37
Maison Carrée at Nismes	—	6	1·00	0·93	1·58
Temple at Jackly	—	6	1·00	0·90	1·62
Pantheon at Rome	—	8	1·00	1·43	1·84

If instead of taking the apparent bulk of a column, that is, as a square pier, we take its real bulk, which is about three quarters ($\frac{3}{4}$) that of a square pier of the same diameter and height; the height of the entablature will be one fourth of the height of the column; for $\frac{3}{4}$ of $\frac{h}{3} = \frac{h}{4}$.

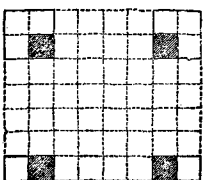

Fig. 866.

There is a curious fact connected with the hypothesis which has been suggested that requires notice; it is relative to the area of the points of support for the edifice which the arrangement affords. In *fig.* 866 the hatched squares represent the plans of quarter piers of columns in a series of intercolumniations every way, such intercolumniations being of two diameters, or four semidiameters. These, added to the quarter piers, make six semidiameters, whose square 36 is therefore the area to be covered with the weight. The four quarter piers or columns=4, hence the points of support are $\frac{4}{36}$ of the area =0·111. Now in the list (1583.) of the principal buildings in Europe the mean ratio is 0·168, differing only 0·057 from the result here given; but if we select the following buildings the mean will be found to differ much less.

Temple of Peace	0·127	
S. Paolo fuori le Murà	0·118	
S. Sabino	0·100	
S. Filippo Neri	0·129	Sum=0·474. Mean $\frac{0{\cdot}474}{4}$ =0·118.

MOULDINGS.

2531. The subservient parts of an order, called mouldings, and common to all the Roman orders, are eight in number. They are—1. The *ovolo, echinus,* or *quarter round.* (*Fig.* 867.) It is commonly found under the abacus of capitals; and is also almost always placed between the corona and dentils in the Corinthian cornice: its form gives it the appearance of seeming fitted to support another member. It should be used only in situations above the level of the eye. 2. The *talon, ogee, or reversed cyma* (*fig.* 868.) is also, like the ovolo, a moulding fit for the support of another. 3. The *cyma, cyma recta,* or *cymatium* (*fig.* 869.) seems well contrived for a covering and to shelter other members; it is only used properly for crowning members, though in Palladio's Doric, and in other examples, it is found occasionally in the bed mouldings under the corona. 4. The *torus* (*fig.* 870.), like the astragal presently to be mentioned, is shaped like a rope, and seems intended to bind and strengthen the parts to which it is applied; while, 5. The *scotia* or *trochilos* (*fig.* 871.), placed between the fillets which always accompany the tori, is usually below the eye; its use being to separate the tori, and to contrast and strengthen the effect of other mouldings as well as to impart variety to the profile of the base. 6. The *cavetto, mouth,* or *hollow*

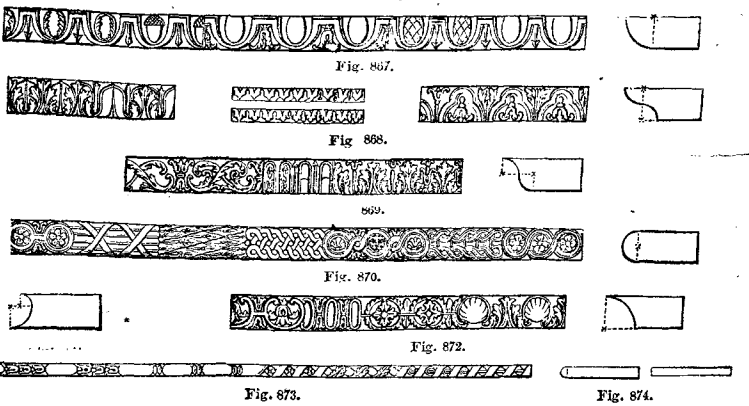

Fig. 867.

Fig 868.

869.

Fig. 870.

Fig. 872.

Fig. 873. Fig. 874.

(*fig.* 872.) is chiefly used as a crowning moulding, like the cyma recta. In bases and capitals it is never used. By workmen it is frequently called a *casement*. 7. The *astragal* (*fig.* 873.) is nothing more than a small torus, and, like it, seems applied for the purpose of binding and strengthening. The astragal is also known by the names of *bead* and *baguette*. 8. The *fillet*, *listel*, or *annulet* (*fig.* 874.) is used at all heights and in all situations. Its chief office is the separation of curved mouldings from one another.

2532. In Grecian examples, the sections of mouldings are obtained by portions of an ellipse, parabola or hyperbola, all parts of a conic section, so that they give a greater delicacy of outline than do the Roman examples. "These latter," writes J. B. Papworth, in his edition (1826) of the work by Sir W. Chambers on *Civil Architecture*, "produced *similar* quantities of middle tint, light, and shadow; the Greeks carefully avoided this sameness, and judiciously and tastefully made the shadows to prevail distinctly. Hence in all their works we find the result of a superior understanding of the principles and effects of light and shade, which are opposed to each other, and relieved with great skill; whereas, in the Roman style, being divided and broken, they are certainly less beautiful and less capable of affording the charms of reflected light than the vestiges of Grecian art,

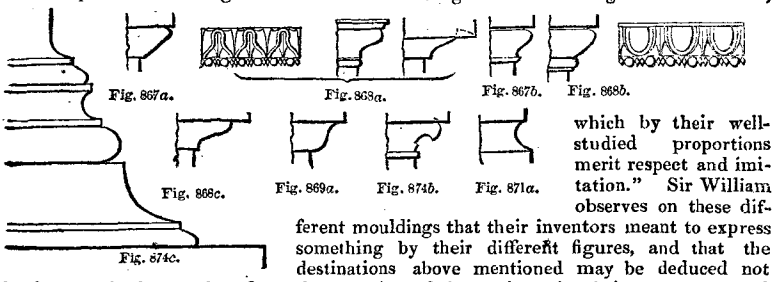

Fig. 867*a*. Fig. 868*a*. Fig. 867*b*. Fig. 868*b*.

Fig. 874*c*.

which by their well-studied proportions merit respect and imitation." Sir William observes on these different mouldings that their inventors meant to express something by their different figures, and that the destinations above mentioned may be deduced not only from their figures, but from the practice of the ancients in their most esteemed works; the cyma and cavetto are constantly used as finishings, and never applied where strength is required; the ovolo and talon are always employed as supporters to the essential members of the composition, such as the modillions, dentils, and corona; the chief use of the torus and astragal is to fortify the tops and bottoms of columns, and sometimes of pedestals; and the scotia is employed only to separate the members of bases, for which purpose the fillet is likewise used not only in bases but in all kinds of profiles.

2533. The names of the Greek mouldings are the same as those already mentioned; and there is another (*fig.* 874*b*.) called from its appearance a *bird's-beak moulding*, comprising the outline of the echinus hollowed out below and then brought down with a curve into the fascia. It is chiefly used in the capital of an *anta* or pilaster, as in *fig.* 883. *Fig.* 867*b*. is a quirked *ogee*, having a separation from the fascia above to obtain a depth of shadow. *Fig.* 868*b*. is a quirked *ovolo*. *Fig.* 867*a*. is used in the cap of the Doric order. *Fig.* 869*a*., *the cyma recta*, used as the crowning member of a cornice, was often elegantly decorated. *Fig.* 868*c*. is an ogee projecting further than the ordinary form. *Fig.* 874*c*. is an outline of the base of the Choragic Monument of Lysicrates at Athens, showing a combination of mouldings; three of the mouldings being inverted. Examples

of Greek capitals are given on pages 906 and 907, in addition to those in *Figs.* 883 and 887.

2534. The simplest method of describing the contours of mouldings in Roman or Italian architecture is to form them of quadrants of circles, as shown in Figs. 867 to 874. Where circumstances justify a variation, the ovolo, talon, cyma, scotia, and cavetto, may be either described from the summits of equilateral triangles, or be composed of portions of the ellipsis, but the section of the torus and astragal is always semicircular.

ORNAMENTS OF MOULDINGS.

2535. In ornamenting the profile of an order, repose requires that some mouldings should be left plain. If all were enriched, confusion instead of variety would result. Except for particular purposes, the square members are rarely carved. There are but few examples in the best age of the art in which the corona is cut; indeed at this moment the only one that occurs to us wherein work is in fine style is that of the three columns in the Campo Vaccino. So where the ovolo above and talon below it are carved, the dentil band between them should be uncut. Scamozzi, in the third chapter of his sixth book, inculcates that ornaments should be neither profuse nor abundant, neither are they to be too sparingly introduced. Thus they will be approved if applied with judgment and discretion. Above all things, they are to be of the most beautiful forms and of the exactest proportions; ornaments in buildings, being like the jewels used for the decoration of princes and princesses and persons of high rank, must be placed only in proper situations. Neither must variety in ornaments be carried to excess. We have to recollect that, being only accessories, they must not obtrude upon but be kept subordinate to the main object. Thus ornaments applied to mouldings should be simple, uniform, and combining not more than two distinct forms in the same enrichment; and when two forms are used on the same moulding they should be cut equally deep, so that an uninterrupted appearance may be preserved. Mouldings of the same form and size on one and the same profile should be similar; and it is moreover a requisite of the greatest importance, so to distribute the centres of the ornaments employed that the centre of one may fall exactly over the centres of those below, of which the columns of the Campo Vaccino form an example for imitation in this respect. Nothing is more offensive than, for example, to see the middle of an egg placed over the edge of a dentil, and in another part of the same moulding to see them come right, centre over centre, and the like negligent and careless distribution. This may always be avoided by making the larger parts regulate the smaller. Thus where there are modillions they must be made to govern the smaller ornaments above and below them, and these smaller ones should always be subdivided with a view to centring with the larger parts. The larger parts are dependent on the axes of the columns and their intercolumniations; but all these must be considered in profiling the order. It will of course be necessary to give the ornaments such forms as may be consistent with the character of the order they enrich. The enrichment of a frieze depends upon the destination of the building, and the ornaments may have relation to the rank, quality, and achievements of the proprietor. We do not agree with Chambers in condemning the introduction of arms, crests, and cyphers, as an unbecoming vanity in the master of the fabric. These may often be so introduced as to indicate the alliances of the family, and thus give a succinct history of its connections. In Gothic architecture we know the practice induced great beauty and variety. We have before observed, in Sect. I. of this Book (2520.), that the instruments and symbols of pagan worship are highly indecorous, not to say ludicrous, on edifices devoted to the Christian religion.

2536. In carving ornaments they must be cut into the solid, and not carved as if they were applied on the solid, because the latter practice alters their figure and proportion. In fact, every moulding should be first cut with its contour plain, and then carved, the most prominent part of the ornament being the actual surface of the moulding before carving, observing that all external and re-entering angles are kept plain, or have only simple leaves with the central filament expressed on or in the angle. In the circular temple of Tivoli the principle of cutting the ornament out of the solid is carried out so far, that the leaves, as usual in most examples of the Corinthian order, instead of being mere appliquées to the bell of the capital, are actually cut out of it.

2537. The degree of relief which ornaments ought to have is dependent on their distance from the eye and the character of the composition: these matters will also regulate the degree of finish they ought to possess. There are some mouldings whose profile is indicative of bearing weight, as the ovolo and talon, which by being deeply cut, though themselves heavy in character, are thereby susceptible of having great lightness imparted to them, whilst such as the cyma and cavetto should not be ornamented deep in the solid. The imitation from nature of the objects represented should be carefully observed, the result whereof will impart beauty and interest to the work on which such attention is bestowed.

CHARACTERS OF THE ORDERS.

2538. In the First Book of this work, Sect. XI. (133, *et seq.*) we have considered the history of the five orders of architecture; we shall here offer some general observations upon them before proceeding to the detail of each separately. The orders and their several characters and qualities do not merely appear in the five species of columns into which they have been subdivided, but are distributed throughout the edifices to which they are applied, the column itself being the regulator of the whole composition. It is on this account the name of orders has been applied to the differently formed and ornamented supports, as columns, which have received the names of the Doric, Ionic, Corinthian, Tuscan, and Composite orders, whereof the three first are of Grecian origin, and the two last, it is supposed, of Italian or Roman origin. Each of these, by the nature of its proportions, and the character resulting from them, produces a leading quality, to which its dimensions, form, and ornaments correspond. But neither of the orders is so limited as to be confined within the expression of any single quality. Thus the strength indicated in the Doric order is capable of being modified into many shades and degrees of that quality. We may satisfy ourselves of this in an instant by reference to the early compared with the later Doric column of the Greeks. Thus the columns of the temple at Corinth are only four diameters high, while those of the portico of Philip are six and a half.

2539. As the Doric seems the expression of strength, simplicity, and their various modes, so the Ionic, by the rise in height of its shaft and by the slenderness of its mass, as well as by the elegance of its capital, indicates a quality intermediate between the grave solidity of the Doric and the elegant delicacy of the Corinthian. Bounded on one side by strength, and by elegance on the other, in the two orders just named, the excess of elegance in the Corinthian order ends in luxury and richness, whereof the character is imprinted on it.

2540. We cannot here refrain from giving, in the words of the excellent Sir Henry Wotton, a quaint and homely, but most admirable description of these five orders, from his *Elements of Architecture*. "First, the *Tuscan* is a plain massive rural pillar, resembling some sturdy, well-limbed labourer, homely clad, in which kind of comparisons, Vitruvius himself seemeth to take pleasure." (Lib. iv. cap. 1.) . . . "The *Dorique order* is the gravest that hath been received into civil use, preserving, in comparison of those that follow, a more *masculine aspect* and little trimmer than the *Tuscan* that went before, save a sober garnishment now and then of *lions' heads* in the *cornice*, and of *triglyphs* and *metopes* always in the *frize*." . . . "To discern him will be a piece rather of good *heraldry* then of *architecture*, for he is knowne by his place when he is in company, and by the peculiar ornament of his *frize*, before mentioned, when he is alone." . . . "The *Ionique order* doth represent a kind of feminine slendernesse; yet, saith Vitruvius, not like a light housewife, but, in a decent dressing, hath much of the *matrone*." . . . "Best known by his trimmings, for the bodie of this *columne* is perpetually *chaneled*, like a thick-pleighted gowne. The *capitall* dressed on each side, not much unlike women's wires, in a spiral wreathing, which they call the *Ionian voluta*." . . . "The *Corinthian* is a columne lasciviously decked like a courtezan, and therefore in much participating (as all inventions do) of the place where they were first born, *Corinth* having beene, without controversie, one of the wantonest towns in the world." . . . "In short, as plainness did characterise the *Tuscan*, so, much delicacie and varietie the *Corinthian* pillar, besides the height of his rank." . . . "The last is the *compounded order*, his *name* being a briefe of his *nature*: for this pillar is nothing in effect but a *medlie*, or an *amasse* of all the precedent *ornaments*, making a new kinde by stealth, and though the most richly tricked, yet the poorest in this, that he is a borrower of his beautie." Each of the orders, says De Quincy, is, then, in the building to which it is applied, the governing principle of the forms, taste, and character of that system of moral order met with in Grecian architecture which alone seems to have suited the physical order of proportions with each part, so that what is agreeable, ornate, and rich is equally found in the whole as in the parts.

2541. On the two Latin orders we do not think it necessary to say more than that they will be fully described in following pages. The invention of new orders must arise out of other expressions of those qualities which are already sufficiently well and beautifully expressed; hence we consider, with De Quincy, to attempt such a thing would be vain. Chambers thus expresses himself on this subject, without the philosophy of De Quincy, yet with the feelings of a learned and experienced architect: "The ingenuity of man has, hitherto, not been able to produce a sixth order, though large premiums have been offered, and numerous attempts been made, by men of first-rate talents to accomplish it. Such is the fettered human imagination, such the scanty store of its ideas, that Doric, Ionic, and Corinthian have ever floated uppermost, and all that has ever been produced amounts to nothing more than different arrangements and combinations of their parts, with some trifling deviations, scarcely deserving notice; the whole tending generally more to diminish than to increase the beauty of the ancient orders." Again: "The suppression of parts of

the ancient orders, with a view to produce novelty, has of late years been practised among us with full as little success; and though it is not wished to restrain sallies of imagination, nor to discourage genius from attempting to invent, yet it is apprehended that attempts to alter the primary forms invented by the ancients, and established by the concurring approbation of many ages, must ever be attended with dangerous consequences, must always be difficult, and seldom, if ever, successful. It is like coining words, which, whatever may be their value, are at first but ill received, and must have the sanction of time to secure them a current reception."

2542. In the progress of the five orders, from the Tuscan up to the Composite, taking seven diameters for the height of the Tuscan column, and eleven for that of the Composite, if the entablature be taken of the same absolute height in all, and at the same time in height one quarter of that of the column, we shall have the height of the entablature in terms of the diameter of the column, as follows: —

In the Tuscan order	$\frac{1}{4}$ of $\frac{7}{1}$	$= 1\frac{3}{4}$ entablature diameters high.
In the Doric order	$\frac{1}{4}$ of $\frac{8}{1}$	$= 2$ entablature diameters high.
In the Ionic order	$\frac{1}{4}$ of $\frac{9}{1}$	$= 2\frac{1}{4}$ entablature diameters high.
In the Corinthian order	$\frac{1}{4}$ of $\frac{10}{1}$	$= 2\frac{1}{2}$ entablature diameters high.
In the Composite order	$\frac{1}{4}$ of $\frac{11}{1}$	$= 2\frac{3}{4}$ entablature diameters high.

HEIGHT AND DIMINUTION OF COLUMNS.

2543. Vitruvius tells us that the ancients were accustomed to assign to the Tuscan column seven of its diameters for the height; to the Doric, eight; to the Ionic, nine; and to the Corinthian and Composite, ten. Scamozzi, the leader of the moderns, adopts similar proportions. But these are not to be considered as more than an approximation to the limits, nor as relating to the proportions between the heights and diameters of the ancient Doric examples, whereof in our First Book we have examined certain specimens. This work cannot be extended to a representation of the variety under which the orders have appeared in their various examples of each order. The works in which they are contained must be consulted for particulars of detail in this respect. Our intention is to give general information on the subject, and to follow, with few exceptions, in that respect, the precepts of Vignola, as tending to the most generally pleasing results, and as being also those which have been adopted on the Continent for general instruction in the art.

2544. We have already spoken (2524, *et seq.*) of the general proportion of the height of the entablature to that of the column as one fourth, and, without returning to the discussion of the propriety of that proportion, will only here incidentally mention that Scamozzi, Barbaro, Alberti, and Palladio have not assigned so great a height to their entablatures, chiefly it appears, because they seemed to consider the slenderness of the columns in the more delicate orders unsuited to the reception of heavy burdens. If, however, the reader will bear in recollection what has been said at the beginning of this section relative to the supports and weights, it will directly occur to him that the practice these great masters sanctioned is not founded upon just deductions. Chambers seems to have had a glimpse of this theory, but without any notion of its developement, when he says, "It must be remembered that, though the height of an entablature in a delicate order is made the same as in a massive one, yet it will not, either in reality or in appearance, be equally heavy, for the quantity of matter in the Corinthian cornice A (*fig.* 875.) is considerably less than in the Tuscan cornice B, and the increased number of parts composing the former of these will of course make it appear far lighter than the latter." He was, however, nearer the exact truth where he speaks in a previous passage of the possibility of increasing the intervals between the columns.

2545. The diminution or tapering form given to a column, whereof all the authors find the type, whether truly or not, in that of the trunk of a tree, in the ancient examples, sometimes commences from the foot of the shaft, sometimes from a quarter or one third of its height, in which case the lower part is a perfect cylinder. Though the latter method has been mostly adopted by modern artists, the former seems more to have prevailed among the ancients. Of the method of entasis, that is, of swelling columns as they rise, we have already spoken in the First Book (144.). A curve of diminution, if we may so term it, in which the lower part does not much vary from the cylinder, but never much exceeding its boundary for the height of one third upwards, is the best, and to something like that we now come. Blondel (*Resolution des quatre principaux Problemes d'Architecture*) says, that the best and simplest instrument for the diminution of columns is that invented by Nicomedes for describing the first conchoid, which, applied at the bottom of the shaft, gives, by continued motion, both the swelling and the diminution. Vignola had not strictly anticipated Blondel in this method, which, it is said, was that used for the columns in the Pantheon; but the old master had come so near to it that we shall first describe Vignola's method, and then that proposed by Blondel. Vignola having already spoken of the common practice, says,

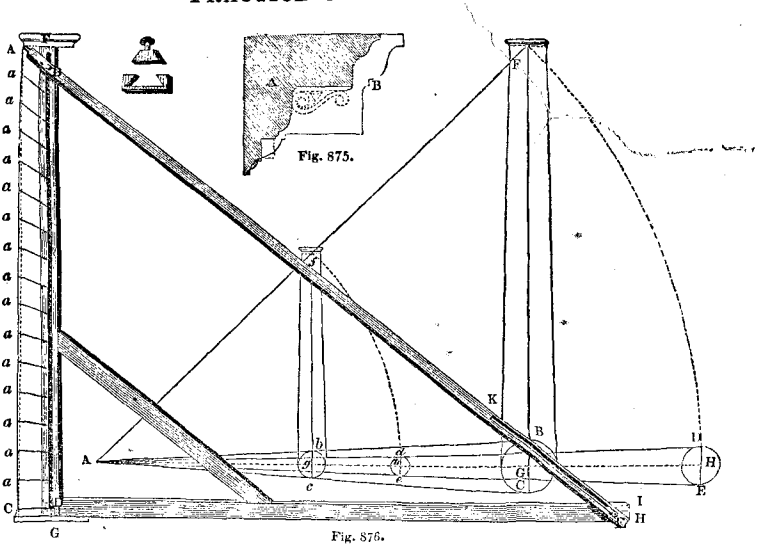

Fig. 875.

Fig. 876.

(Stampani's edit. *Dei cinque Ordini d'Architettura*, Roma, 1770, cap. 7. p. 51.), "In respect of this second mode, it is my own discovery, and will be soon understood by the figure, though not so well known as the first named. The measures of the column having been fixed, namely, the height of the shaft and its upper and lower diameters, from C (*fig.* 876.), draw an indefinite line through D perpendicular to the axis of the column. From A, the extreme point of the upper semi-diameter, to B, a point in the axis, set off CD the lower semidiameter. Through B from A draw the line ABE, cutting the indefinite line CD in E, and from the point of intersection E and through the axis of the column draw any number of rays, as EB*a*, whereon, from the axis towards the circumference, setting off the interval CD, any number of points *aaa* may be found, and through them a curve being drawn gives the swell and diminution of the shaft.

2546. This method is so far defective as to require the curve to be drawn by hand on the application of a flexible ruler through the points found. To remedy the defect, Blondel, who on investigation of the curve found it to be a conchoid, applied the instrument of Nicomedes for the purpose, the description of which instrument here follows. The height of the shaft and the upper and lower diameters of the column having been determined, as also the length (*fig.* 876.) of the line CDE, take three rulers, FG, ID, and AH, of which let FG and ID be fastened together at right angles in G. From top to bottom let a dovetail groove be cut down the middle of FG, and at E on the ruler ID, whose length from the centre of the groove in FG is the same as that of the point of intersection from the axis of the column, fix a pin. On the ruler AH set off the distance AB equal to the lower semidiameter of the column CD, and at the other end of the ruler cut a slit through it from H to K, the length whereof must at least be equal to the difference in length between EB and ED, and its breadth sufficient to admit the pin fixed at E to pass through the slit, and allow the ruler to slide thereon. Now, the middle of the groove in the ruler FG being placed exactly over the axis of the column, the ruler AH in moving along the groove will with its extremity A describe the curve A*aa*C, which curve is the same as that produced by Vignola's method, except that the operation is performed by the continued motion of the ruler AH. If the rulers be of an indefinite size, and the pins at E and B be made to move along their respective rulers, so as to be able to increase or diminish at pleasure the lengths AB and DE, the instrument will answer for drawing columns of any size.

2547. The diminution of the column as respects quantity is rarely in ancient examples less than one eighth of the lower diameter of the column, nor often more than one sixth, as will be seen in the subjoined examples. One sixth is the diminution recommended by Vitruvius, and followed by Vignola, in all his orders, except the Tuscan. In the following table the first column contains the order; the second, the example; the third, the height of the column in English feet and decimal parts of a foot; the fourth column shows its diameter in similar terms; and the fifth the ratio of diminution. The dimensions are from Perrault, reduced here from French to English feet.

Order.	Examples.	Height of Column in English Feet.	Diameter of Column in English Feet.	Ratio of Diminution.
Doric	Theatre of Marcellus	22·386	3·198	0·200
—	Coliseum	24·384	2·865	0·077
Ionic	Temple of Concord, now of Saturn	38·376	4·485	0·182
—	Temple of Fortuna Virilis	24·340	3·109	0·125
—	Coliseum	24·518	2·909	0·166
Corinthian	Temple of Peace	52·400	6·041	0·111
—	Portico of Pantheon	38·998	4·796	0·106
—	Altars of Pantheon	11·548	1·465	0·133
—	Temple of Vesta	29·226	3·109	0·111
—	Temple of the Sybil at Tivoli	20·254	2·487	0·133
—	Temple of Faustina	38·376	4·796	0·133
—	Temple of the Dioscuri	39·975	4·840	0·111

—	Temple of Bacchus	11·371	1·443	0·111
—	Arch of Titus	17·056	2·102	0·117
—	Arch of Septimius Severus	23·097	2·877	0·117

2548. The recommendation of Vitruvius (lib. iii. c. 2.) to give different degrees of diminution to columns of different heights has been combated by Perrault in his notes on the passage; and we are, with Chambers, of opinion that Perrault is right in his judgment, inasmuch as the proper point of view for a column fifty feet high (*fig.* 876. unshaded part) ought not to be at the same distance as for one of fifteen, the point being removed more distant as the column increases in height, and therefore the apparent relation between the upper and lower diameters would appear the same. For supposing A to be a point of view whose respective distance from each of the columns *fg* FG, is equal to the respective heights of each, the triangles *f*Ag FAG will be similar; and A*f*, or A*h*, which is the same, will be to A*g*, as AF, or its equal AH, is to AG: therefore, if *de* be in reality to *bc* as DE is to BC, it will likewise be apparent so: for the angle *d*A*e* will then be to the angle *b*A*c*, as the angle DAE is to the angle BAC; and if the real relations differ, the apparent ones will likewise differ. "When, therefore," observes Chambers, "a certain degree of diminution, which by experience is found pleasing, has been fixed upon, there will be no necessity for changing it, whatever be the height of the column, provided the point of view is not limited; but in close places, where the spectator is not at liberty to choose a proper distance for his point of sight, the architect, if he inclines to be scrupulously accurate, may vary; though it is, in reality, a matter of no importance, as the nearness of the object will render the image thereof indistinct, and, consequently, any small alteration imperceptible." Our author afterwards adds: "It must not, however, be imagined that the same general proportions will in all cases succeed. They are chiefly collected from the temples and other public structures of antiquity, and may by us be employed in churches, palaces, and other buildings of magnificence, where majesty and grandeur of manner should be extended to their utmost limits, and where, the composition being generally large, the parts require an extraordinary degree of boldness to make them distinctly perceptible from the proper general points of view."

SUBDIVISION OF ENTABLATURES.

2549. We have spoken of the entablature as the fourth part of the height of the column. In general terms, its subdivisions of architrave, frieze, and cornice are obtained by dividing its height into ten equal parts, whereof three are given to the architrave, three to the frieze, and four to the cornice; except in the Roman Doric order, in which the whole height of the entablature is divided into eight parts, of which two are given to the architrave, three to the frieze, and three to the cornice. From these general proportions variations have been made by different masters, but not so great as to call for particular observation. They deviate but little from the examples of antiquity; and the ease with which they may be recollected render them singularly useful.

MODE OF MEASURING THE ORDERS.

2550. Several methods have been used for forming the scale of equal parts, by which the orders are measured; but they are all founded on the diameter of the column at the bottom of the shaft; for those that use the module or semi-diameter as the measuring unit (which all have done in the Doric order) must still recur to the diameter itself. The authors have also usually divided it into thirty parts, but all concur in measuring by an unit founded on the diameter. We shall follow the practice of Vignola in describing the orders, that master dividing the diameter into two equal parts, of which each is the unit of the scale for

profiling the order. The *module* for the two first orders, the Tuscan and Doric, is divided into twelve parts or *minutes*; and for the Ionic, Corinthian, and Composite orders into eighteen parts, by which minute fractions are avoided.

2551. For drawing or *profiling*, as it is called, an order, the proper way is to set out the height of the leading parts and their projections, and then proceed to the subdivisions of each. As a general rule, we may mention that it is usual to make projections of cornices nearly or quite equal to their heights.

APPLICATION OF THE ORDERS.

2552. The application of the orders among the ancients was exceedingly extensive. Porticoes abounded about their cities; their temples were almost groves of columns, with which also were profusely decorated their theatres, baths, basilicæ, and other public buildings, as were no less the courts, vestibules, and halls of their private dwellings. The moderns have in a great measure imitated their example, and their use has very much exceeded the limits of propriety. The maxim of Horace, "Nec Deus intersit," has in no case been more violated by architects than in the unnecessary introduction of the orders on the façades of their buildings. The test of fitness being applied to their employment is the best that the young architect can adopt.

Sect. III.

THE TUSCAN ORDER.

2553. The reader, in *fig.* 877., has before him the geometrical representation of the Tuscan order and its details. A shows the plan of the sofite of the cornice, and B is a plan of the capital. The example is from Vignola's profile, whereon we consider it proper to remark, in conformity with an opinion before expressed (2532, 2533.), that the ovolo which crowns the cornice is an improper moulding for the situation it occupies. The substitution for it of a fillet and cyma recta would have been much more suitable, and would have also been more pleasant in effect.

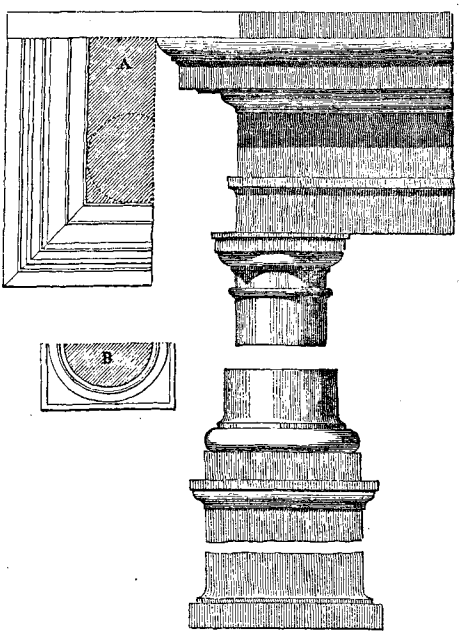

Fig. 877.

2554. "The Tuscan order," says Chambers, "admits of no ornaments of any kind; on the contrary, it is sometimes customary to represent on the shaft of its column rustic cinctures, as at the Palace Pitti in Florence, that of the Luxembourg in Paris, York Stairs in London, and many other buildings of note. This practice, though frequent, and to be found in the works of many celebrated architects, is not always excusable, and should be indulged with caution, as it hides the natural figure of the column, alters its proportions, and affects the simplicity of the whole composition. There are few examples of these bandages in the remains of antiquity, and in general it will be advisable to avoid them in all large designs, reserving the rustic work for the intercolumniations, where it may be employed with great propriety, to produce an opposition which will help to render the aspect of the whole composition distinct and striking." Our author proceeds to observe, that "in smaller works, of which the parts being few are easily comprehended, they may be sometimes tolerated, sometimes even recommended, as they serve to diversify the forms, are productive of strong contrasts, and contribute very considerably to the masculine bold aspect of

the composition." Le Clerc allows their propriety in the gates of citadels and prisons, and also considers them not out of place for gates to gardens or parks, for *grottoes*, fountains, and baths. Delorme made abundant use of them in several parts of the Thuilleries, covering them with arms, cyphers, and other enrichments. They are to be found in the detail of the Louvre, with vermiculated rustics. De Chambrai, who banishes the Tuscan order to the country, nevertheless admits that the Tuscan column may be consecrated to the commemoration of great men and their glorious actions, instancing Trajan's column, one of the proudest monuments of Roman splendour, as also the Antonine column.

2555. Having adjusted the size of the module with its subdivisions of twelve parts, so that the paper or other material on which the order is profiled may contain the whole of the order, it always being understood that the representation for practical purposes need not include the whole height of the shaft of the column, whose minutiæ of diminution may form the subject of a separate drawing, the first step is to draw a perpendicular line for the axis of the column. Parallel to the base lines are then to be drawn, according to the dimensions (parts of the module) given in the table subjoined; and the beginner, as well as the more practised man, is recommended not to set up these as they are given separately, but in every case to add the succeeding dimensions to those preceding rather than to set them off one by one, which, on a small scale, causes minute errors in reading off from the scale to become in the end large in amount. By the adoption also of such a practice the work corrects itself as it proceeds. As the heights are set up, the projection of each member from the axis of the column is to be set off, and this should be always done on both sides at the same time, by which *gulling* of the paper from the point of the compasses, and errors in other respects, are avoided. The *fig.* 878. is

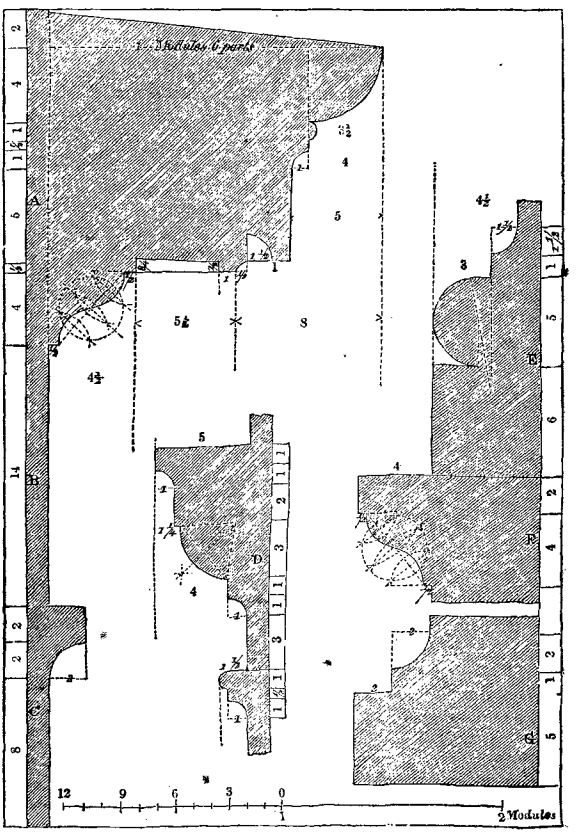

Fig. 878.

but the detail on a larger scale of the general representation exhibited in that preceding The measures of each part are given in the following table.

TABLE OF THE PARTS OF THE TUSCAN ORDER.

Mouldings whereof the Parts are composed.			Heights of Mouldings in Parts of a Module.	Projection from the Axis of Column in Parts of a Module.
ENTABLATURE.				
Cornice A, 16 parts.	Cymatium, and parts.	Quarter round	4	27½
		Astragal	1	
		Fillet	½	23½
		Congé, or cavetto	1	22½
		Corona	5	22½
		Drip	1	21½
		Sinking from corona, or hollow	½	19½
		Fillet	½	14
	Bed moulding	Ogee	4	13½
Frieze B, 14 parts.			14	9½
Architrave C, 12 parts.	Fillet.	Fillet, or listel	2	11½
	Fascia.	Congé, or small cavetto	2	9½
		Fascia	8	9½
The height of the drip under the corona is taken on that member, and that of the hollow in the height of the fillet.				
COLUMN.				
Capital D, 12 parts.	Abacus.	Fillet	1	14½
		Congé, or cavetto	1	13½
		Band	2	13½
	Cymatium.	Ovolo	3	13½
		Fillet	1	10½
		Congé, or cavetto	1	9½
	Neck, or Hypotrachelion		3	9½
Shaft, 12 modules.	Astragal, or necking.	Bead	1	11
		Fillet	½	10½
		Congé, or cavetto	1	9½
	Shaft.	Shaft	11 mod. 8 parts.	9½
		Congé, or apophyge	1½	12
Base, E, 12 parts.		Fillet	1	13½
		Torus	5	16½
		Plinth	6	16½
PEDESTAL.				
Cornice G, 6 parts.	Cymatium.	Listel	2	20½
		Ogee	4	20
Die F, 44 parts.		Die, or dado	3 mod. 4 parts.	16½
		Congé, or apophyge	2	16½
Base, 6 parts.		Fillet	1	18½
		Plinth	5	20½

2556. Vitruvius in this order forms the columns six diameters high, and makes their diminution one quarter of the diameter. He gives to the base and capital each one module in height. No pedestal is given by him. Over the capital he places the architrave of timber in two thicknesses connected together by dovetailed dowels. He however leaves the height unsettled, merely saying that their height should be such as may be suitable to the grandeur of the work where they are used. He directs no frieze, but places over the architrave cantilevers or mutuli, projecting one fourth part of the height of the column, including the base and capital. He fixes no measure for the cornice, neither does he give any directions respecting the intercolumniations of this order. The instructions are not so specific as those which he lays down for the other orders, and there have been various interpretations of the text, which unfortunately cannot in any of the suppositions be tested

on ancient remains. The whole height, according to the measuring unit which we have adopted from Vignola, is 16 modules and 3 parts.

2557. Palladio makes the height of his Tuscan column 6 diameters, and diminishes the shaft one fourth of a diameter. The height of the base and capital are each half a diameter. He provides no pedestal, but, instead thereof, places the base of the column on a zoccolo, or lofty plinth, whose height is equal to the diameter of the column. He leaves the intercolumniation unsettled, merely hinting that as the architraves are of timber, they, the intercolumniations may be wide. The whole height by him assigned to the order is 9 diameters and three quarters of the column. The whole height according to our scale is 19 modules and 6 parts.

2558. Serlio makes the column of the order 5 diameters exclusive of base and capital, each of which are half a diameter in height, and his diminution is one quarter of the diameter. He gives half a diameter to the height of the architrave, and an equal height to the frieze and to the cornice. His pedestal is with a plinth and base, a die, and cymatium, the whole being a third of the height of the column. He gives no rules for the intercolumniations, though in book 4. he inserts a diagram wherein intercolumns appear, merely saying that they are equal to 3 diameters. The total height according to our measure is 19 modules and 3 parts.

2559. Scamozzi makes the shaft of his column 6 diameters, and diminishes it one fourth part of its diameter. The heights of the base and capital are each half a diameter. To the entablature he assigns for height one fourth of the height of the column, including its base and capital, less half its diameter. He places a sort of triglyph in the frieze, which arises from a misconception of the text of Vitruvius. The height of his pedestal is a fourth part of that of the column, with base and capital, less half a diameter. The whole height in our measure is 21 modules and 9 parts.

SECT. IV.

THE DORIC ORDER.

2560. The Doric order of the moderns is of two sorts: mutular and denticular, the former is represented in *fig.* 879. A is a plan of the sofite of the corona; B, a plan of the

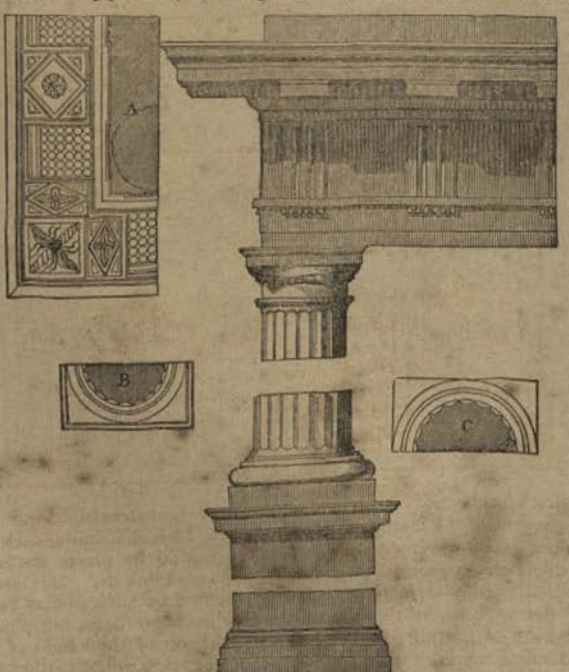

Fig. 879.

capital; and C, a plan of the base. In the frieze the channelled projections are called *triglyphs*, and the spaces between them *metopæ*, which should in breadth be equal to their

height, which is that of the frieze. The shaft is usually channelled with twenty *flutes*. Over the triglyphs are distributed *mutules* or modillions, and another peculiarity is the introduction of *guttæ* or *drops*, which decorate the sofite of the cornice and the feet of the triglyphs.

2561. Daviler, speaking of the two Doric entablatures given by Vignola, admires the elegance of their composition, and scarcely knows which of them to select as the most beautiful. "The first" (or denticular), hereafter immediately subjoined, says Chambers, following that author, "which is entirely antique, is the lightest, and consequently properest for interior decoration or objects intended for near inspection; the other, composed by Vignola himself from various fragments of antiquity, being bolder, and consisting of larger parts, seems better calculated for outside works and places where the point of view is either distant or unlimited. On polygonal plans, however, the mutule cornice must be avoided, because the sofites of the angular mutules would form irregular and very disagreeable figures: neither should it be employed in concaves of small dimensions, for the same reason; nor in places where frequent breaks are requisite, it being extremely difficult, often impossible, to prevent the mutules from penetrating and mutilating each other in various unsightly manners; and wherever this cornice is used on a convex surface, the sides of the mutules must be made parallel, for it would be both disagreeable and unnatural to see them broader, and consequently heavier in front than where they spring out of the mutule band." We have elsewhere observed that there is very great difficulty in distributing the parts of the Doric entablature, on account of the intervals between the centres of the triglyphs, which necessarily confine the composer to intercolumniations divisible by three modules, thus producing spaces which are often too wide or too narrow for his purposes.

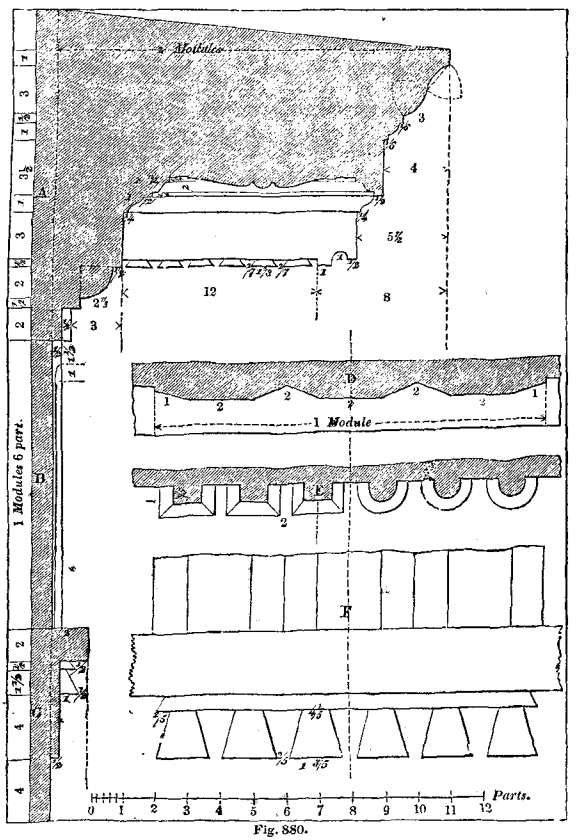

Fig. 880.

2562. In *fig.* 880. the entablature of the mutular Doric order is given to a larger scale than that of the preceding figure; and we subjoin, as in the Tuscan order,—

TABLE OF PARTS OF THE ENTABLATURE OF THE MUTULAR DORIC.

	Mouldings whereof the Parts are composed.	Heights of Mouldings in Parts of a Module.	Projections from Axis of Column in Parts of a Module.
Cornice A, 18 parts.	Fillet of the corona	1	34
	Cyma	3	31
	Fillet	$\frac{1}{2}$	31
	Cyma reversa	1	$30\frac{3}{4}$
	Corona	$3\frac{1}{2}$	30
	Cyma reversa	1	$29\frac{1}{2}$
	Mutule	3	$28\frac{1}{2}$
	Drip	$\frac{1}{2}$	28
	Gutta of the mutule	$\frac{1}{2}$	26
	Echinus, or quarter round	2	$13\frac{1}{2}$
	Fillet	$\frac{1}{2}$	$11\frac{1}{2}$
	Capital of the triglyph	2	11
Frieze B, 18 parts.	Triglyph	18	$10\frac{1}{2}$
	Metope	18	10
Architrave C, 12 parts.	Listel	2	12
	Capital of the guttæ	$\frac{1}{2}$	$11\frac{1}{2}$
	Guttæ	$1\frac{1}{2}$	$11\frac{1}{2}$
	First fascia	6	$10\frac{1}{2}$
	Second fascia	4	10

D is the plan of a triglyph to double the scale.
E is the plan of the round or square guttæ.
F is the elevation of the triglyph and its guttæ.

2563. To obviate the difficulties mentioned in 2561. relative to the triglyphs, they have often been omitted and the entablature left plain, as in the Coliseum at Rome, the colonnades of St. Peter's of the Vatican, and in many other buildings. This, says Chambers, is an easy expedient; but as it robs the order of its principal characteristic distinction, the remedy is a desperate one, and should only be employed as a last resource.

2564. The Doric order was used by the ancients in temples dedicated to Minerva, to Mars, and to Hercules. In modern buildings, Serlio (lib. iv. c. 6.) recommends it in churches dedicated to saints remarkable by their suffering for the Christian faith. Le Clerc suggests its use for military buildings. "It may," says Chambers, "be employed in the houses of generals, or other martial men, in mausoleums erected to their memory, or in triumphal bridges and arches built to celebrate their victories."

2665. As the difference between the mutular and denticular Doric lies entirely in the entablature, we give in the following table the whole of the details of the order,

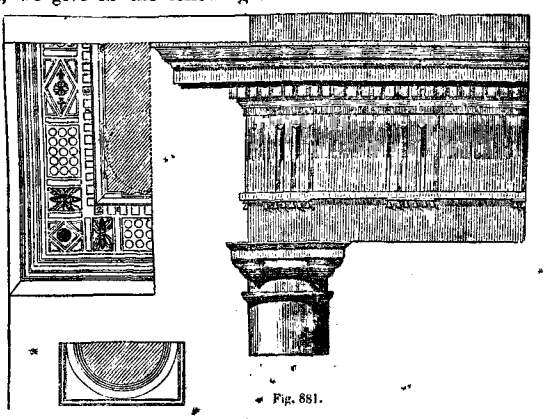

Fig. 881.

observing, that from the capitals downwards, the measures assigned to them are the same for each. *Fig.* 881. represents the entablature of the denticular Doric and its parts,

which, with those of the capital, base, and pedestal, are in *fig.* 882. given to a larger

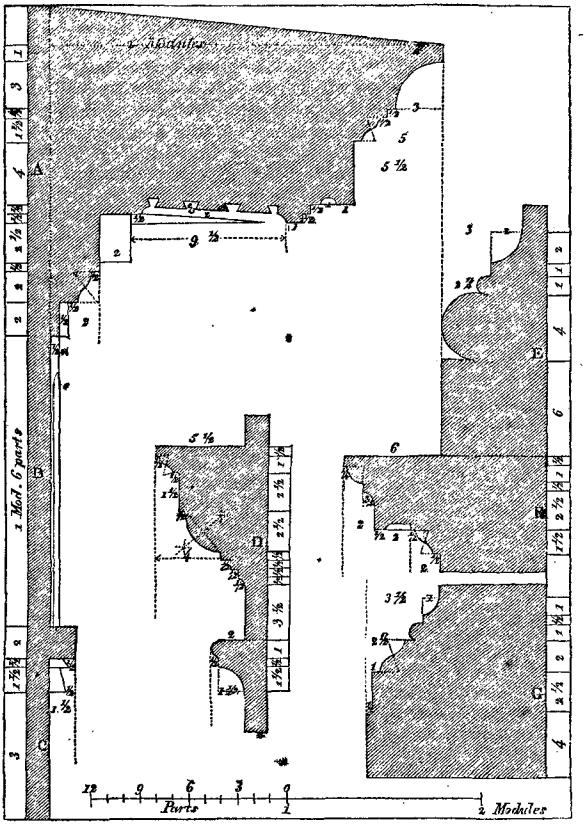

Fig. 882.

scale, as we have before represented the parts of the Tuscan order. The general table is subjoined: —

Members composing the Order.		Heights in Parts of a Module.	Projections in Parts of a Module from Axis of Column.
	Entablature.		
A, Cornice, 18 parts.	Fillet of corona	1	34
	Cavetto	3	31
	Fillet	$\frac{1}{2}$	26
	Cyma reversa	$1\frac{1}{2}$	30
	Corona	4	$28\frac{1}{2}$
	Drip	$\frac{1}{2}$	$27\frac{1}{2}$
	Fillet	$\frac{1}{2}$	25
	Gutta under the corona	$\frac{1}{2}$	$24\frac{1}{2}$
	Dentil	3	15
	Fillet	$\frac{1}{2}$	13
	Cyma reversa	2	$12\frac{1}{2}$
	Capital of triglyph	2	11
B, Frieze, 18 parts.	Triglyph	18	$10\frac{1}{2}$
	Metope	18	10

Members composing the Order.		Heights in Parts of a Module.	Projections in Parts of a Module from Axis of Column.
C, Architrave, 10 parts.	Listel	2	11½
	Capital of guttæ	½	11
	Guttæ	1⅓	11
	Fascia	10	10
	COLUMN.		
D, Capital, 12 parts.	Listel	½	15½
	Cyma reversa	1	15¼
	Band	2½	14
	Echinus or quarter round	2½	13¾
	Three annulets	1½	11½
	Neck of capital	4	10
	Astragal: Ovolo	1	12
	Astragal: Fillet	½	11½
	Astragal: Congé	1½	10
	SHAFT OF THE COLUMN, 14 modules.		
E, Base, 12 parts.	Apophyge or congé	2	12
	Fillet	⅔	14
	Astragal	1⅓	14¾
	Torus	4	17
	Plinth	6	17
	PEDESTAL.		
F, Cornice, 6 parts.	Listel	½	23
	Echinus	1	22¾
	Fillet	½	21¾
	Corona	2½	21
	Cyma reversa	1½	18½
	DIE OF THE PEDESTAL, 4 modules.		
G, Base, 10 parts.	Congé	1	17
	Fillet	½	18
	Astragal	1	18¾
	Inverted cyma	2	19
	Second plinth	2½	21
	First plinth	4	21½

2566. Vitruvius, with more clearness than in the others, describes the Doric order (book iv. chap. iii.). In order to set out its proportions, he tells us, though not giving a direct rule, that its pedestal is composed of three parts, the cymatium or cornice, the die, and the base; and that the base and cimatium are composed of many mouldings, whose individual proportions, however, he does not give. He assigns no particular base to the Doric order; but, nevertheless, places under half a diameter in height the attic base, whose members are the plinth, small fillet, scotia, and the upper torus with its superior and inferior fillets, together with the apophyge of the column. He gives to the projection of the base a fifth part of the diameter of the column. The height of the shaft he makes of 6 diameters, and its diminution a sixth part of the diameter. The capital's height he makes equal to half a diameter, and divides it into three parts, one for the abacus and its cymatium, another for the echinus and its fillets, the third for the hypotrachelium. To the architrave he assigns the height of one half diameter of the column, and to the frieze 50 parts of the module semidiameter divided into 30 parts), including the fascia, forming the capital of the triglyphs. His cornice consists of 30 parts of the module, and its projection 40. The whole height which he gives to the order is, in the measure here adopted, 17 modules and 20 parts.

2567. Palladio makes the Doric pedestal rather less than 2½ diameters of the column, dividing it into three parts, the base, die, and cymatium. To the die he assigns nearly a diameter and one third of the column. To the cymatium a little more than one third of the diameter. He uses the attic base to the order, but, for the sake of carrying off the water, turns the plinth into an inverted cavetto (*guscio*), ending in the projection of the

cymatium of the pedestal. To the shaft of the column he assigns various proportions, directing that if accompanied with pilasters, it should be of the height of $8\frac{5}{12}$ diameters, and if entirely isolated, 7 or at most 8 diameters high. He cuts the shaft into 24 flutes, and diminishes it the tenth part of its diameter. The height of his capital is half a diameter, and, like the annotators on Vitruvius, he decorates the neck or frieze, as they both call it, with roses, adding, however, other flowers, and making its projection a little more than a fifth part of the diameter. To the architrave, frieze, and cornice he gives a little more than one fourth part of the height of the column, so that the whole height of his order is in our measure 24 modules and a fraction above $2\frac{1}{2}$ parts.

2568. Serlio makes the height of the pedestal of his column a little less than 3 diameters, with its base, die, and cymatium. The height of the die is set up equal to the diagonal of a square, formed on the plinth of the column. The height of the cymatium, according to the strict text of Serlio, should not be less than that of the base; but he altogether omits any mention of its projection. His base is the attic base, to which he assigns a projection of a quarter of a diameter. The column is 6 diameters high, and has 20 flutes. His capital differs only from that of Vitruvius in its projection, which is rather more. The architrave and frieze do not much differ from those already described. The projection given to the cornice is equal to its height. The whole height in our measures amounts to 23 modules and 5 parts.

2569. The Doric order as described by Scamozzi is not very dissimilar to those already described. The pedestal is by him made 2 diameters and a little more than a quarter, with a base, die, and cymatium, and the projection barely a quarter of the diameter of the column, to which he gives the attic base. His column is $7\frac{1}{2}$ diameters high, and the diminution a fifth part of the diameter. There are 26 flutes on the shaft, separated from each other by fillets, whose width is one third of the flute. This author gives three different sorts of capitals for the order: the first has three annulets; the second has only the lower annulet, the two upper ones being changed to an astragal; the third, instead of the two lower annulets, has a cyma reversa. Lastly, above the corona he places a cyma reversa, and in the other parts does not vary much from the preceding authors, especially in the frieze and architrave, except that in the last he uses two fasciæ. To the cornice he assigns the projection of five sixths of a diameter of the column. His whole entablature is a little less than one fourth the height of the column, including base and capital. The whole height of the order in our measures is 23 modules and 8 parts.

2570. In *fig.* 883. the profile of the Grecian Doric from the Parthenon at Athens is given. Though very different to those we have already described of this order, the resemblance is still considerable. Its character is altogether sacred and monumental, and its application, if capable of application to modern purposes, can scarcely be made to any edifice whose general character and forms are not of the severest and purest nature. The various absurd situations in which the Grecian Doric has been introduced in this country, has brought it into disrepute; added to which, in this dark climate the closeness of the intercolumniations excludes light, which is so essential to the display of architecture under the cloudy skies with which we are constantly accompanied in high latitudes. The diameter of the columns in the original is 6 feet 2·7 inches.

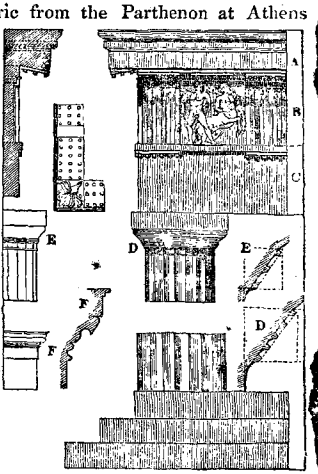

Fig. 883.

2571. Lest we may be reproached with neglecting to submit to the student in this place (and the remark equally applies to the following section on the Ionic order) more examples of the Grecian Doric, we would here observe that this work is not to stand in place of a parallel of the orders. Nothing would have been easier than to have placed before him an abundance of examples; but they must be sought elsewhere, inasmuch as the nature of our labours requires general, not special, information in this respect. We have not, however, refrained in the first book (142, *et seq.*) from entering into details respecting the Grecian Doric, which we consider much more valuable to the reader than would be the exhibition of a series of profiles of its principal examples. We have, moreover, at that place, suggested some criteria of their comparative antiquity. We do not think the nice copying of a profile into a modern work any other than a disgraceful exhibition of the want of ability in the man, we cannot call him artist, who adopts it, and shall be much better pleased to leave the student in doubt, so that he may apply himself *pro re natâ* to the matter which calls his genius into play. From what we have said of *the orders* in Sect. II. of this Book, (2523, *et seq.*), relative to the order, and on *moulding*

(2532, *et seq.*), it must be quite clear that the variety of every order, keeping to first principles, has not been yet exhausted, neither is it likely to be so.

TABLE OF THE PARTS OF THE GRECIAN DORIC (PARTHENON).

Members composing the Order.		Heights in Parts of a Module and Decimals.	Projections in Parts of a Module from Axis of Column.
	ENTABLATURE.		
A, Cornice, 15·32 parts.	Fillet	0·60	22·10
	Echinus	3·12	20·40
	Fillet, with sunk cyma reversa	2·20	
	Corona	4·88	18·98
	Fillet	1·10	18·80
	Capital of mutules	1·10	
	Mutules	0·32	18·66
	Bead and capital of triglyphs	2·00	11·46
B, Frieze, 14·88 parts.	Frieze (in metope)	15·12	
	Triglyph	14·88	11·40
C, Architrave, 17·10 parts.	Fillet	1·50	12·50
	Cap of guttæ	1·00	12·40
	Guttæ	0·20	
	Architrave below guttæ	14·40	11·20
	COLUMN.

	Fillets and hollows, with cavetto	0·80	
	Neck	2·20	9·44
	Groove or sinking	0·16	
	Shaft	20·30	at top 9·38; at bottom 12·00
	First step or plinth	6·90	12·80
	Second step or plinth	6·70	21·80
	Third step or plinth	6·90	30·84

2572. The minutiæ of the Grecian Doric, as we have just observed, cannot be given in a general work of this nature. In its smaller refinements it requires plates on a much larger scale than this volume allows. The reader, therefore, must be referred to *Stuart's Antiquities of Athens* (original edition), and the publications of the Dilettanti Society, for the information on the subject of the Grecian Doric. All that was here possible was to give a general idea of the order. In the figure, E is the section of the capitals of the inner columns of the temple on a larger scale. DD relate to the principal columns. F is a section of one of the antæ or pilasters to double the scale of the capital. The centre intercolumniation 4 modules $\frac{48}{100}$ from axis to axis of columns. The principal Grecian Doric temples are — the Parthenon, the temple of Theseus, the propylæum and the portico of the Agora at Athens; the temple of Minerva at Sunium; the temple at Corinth; of Jupiter Nemæus, between Argos and Corinth; temple of Apollo and portico of Philip in the island of Delos; the temple of Jupiter Panhellenius at Egina, and of Apollo Epicurius at Phigalia; the two temples at Selinus; that of Juno Lucina and Concord at Agrigentum; the temple at Egesta, and the three temples at Pæstum. (See 142, *et seq.*)

SECT. V.

THE IONIC ORDER.

2573. Of the Ionic order there are many extant examples, both Grecian and Roman; and, except the debased later examples of the latter, there is not that wide difference between them that exists between the Grecian and Roman Doric. The Ionic has been considered as deficient in appearance as compared with the other orders, on account of

the irregularity of its capital, which, on the return, presents difficulties in use. These difficulties are not obviated by the practice of the Greeks, who made an angular volute on each extremity of the principal façade, and then returned the face of the capital. With all our respect for Greek art, we think the expedient, though ingenious, a deformity; albeit, in the case of the type being a timber architrave, we must admit that the face of the capital should lie in the direction of the superincumbent beam.

2574. In the example given (*fig.* 884.) we have, as in the examples of the preceding

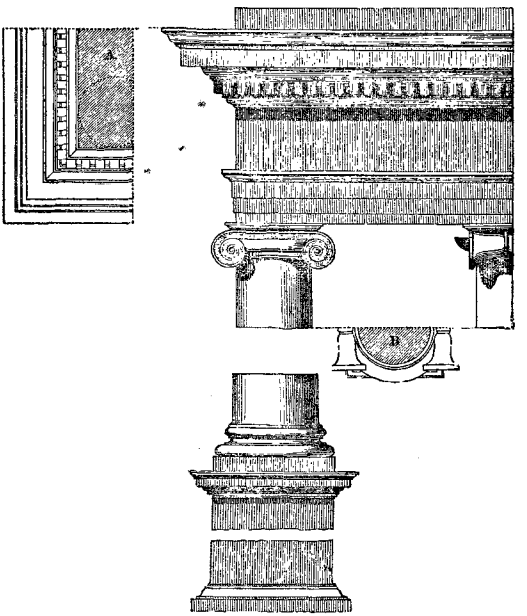

Fig. 884.

orders, selected the profile of Vignola as the most elegant of the moderns; and the reader will here recollect that in the Ionic, Corinthian, and Composite orders, the module or semi-diameter of the column is divided into 18 parts. In the figure, A is a plan of the soffite of the cornice, and B a plan of the capital. The method of tracing the volute will be given in a subsequent figure: previous to which, as in the orders already given, we subjoin a table showing the heights and projections of the parts of the order.

The flutes in this order are separated by a listel.

2575. The letters to the leading divisions of the above table refer to the *fig.* 885., wherein the parts are drawn to a larger scale, and wherein I is the eye of the volute, presently to be described.

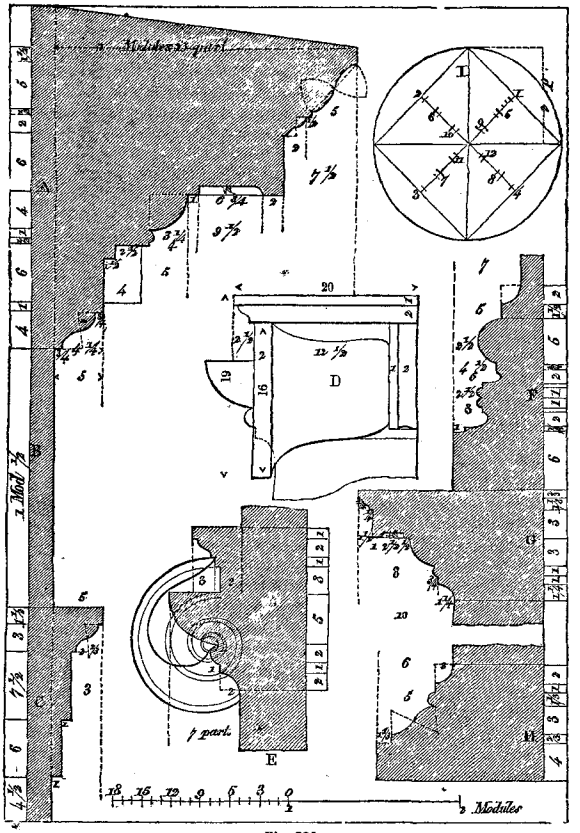

Fig. 885.

2576. *Fig.* 886. shows the method of drawing the volute, the centre of whose eye, as it is called, is found by the intersection of an horizontal line from E, the bottom of the

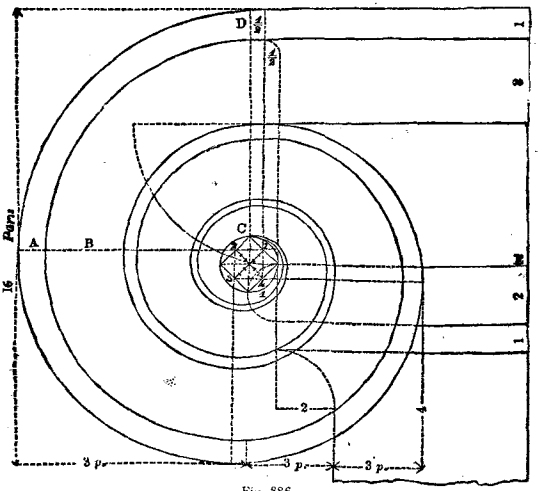

Fig. 886.

See fig. 618c.

echinus, with a vertical from D, the extremity of the cyma reversa. On the point of intersection, with a radius equal to one part, describe a circle. Its vertical diameter is called the *cathetus*, and forms the diagonal of a square, whose sides are to be bisected, and through the points of bisection (see I, *fig.* 885.) the axes 1, 3 and 2, 4 are to be drawn, each being divided into 6 equal parts. The points thus found will serve for drawing the exterior part of the volute. Thus, placing the point of the compasses in the point 1, with the radius 1 D, the quadrant D A is described. With the radius 2 A another quadrant may be described, and so on. Similarly, the subdivisions below the points used for the outer lines of the volute serve for the inner lines. The total height of the volute is 16 parts of a module, whereof 9 are above the horizontal from E, and 7 below it.

2577. Vitruvius, according to some authors, has not given any fixed measures to the pedestal of this order. Daniel Barbaro, however, his commentator, seems to think otherwise; and, on this head, we shall therefore follow him. The height of the pedestal is made nearly a third part (including its base and cymatium) of the height of the column. To the base of the column he assigns half a diameter, and to the shaft itself nearly 8 diameters, its surface being cut into 24 flutes, separated by fillets from each other. His method of describing the volute is not now thoroughly understood; and it is, perhaps, of little importance to trouble ourselves to decypher his directions, seeing that the mode of forming it is derived from mathematical principles, as well understood now as in the days of the author. The architrave he leaves without any fixed dimensions, merely saying that it must be larger or smaller according to the height of the columns. He prescribes, however, that the architrave, frieze, and cornice should together be somewhat less than a sixth part of the height of the column, with its base and capital. The total height he makes the order, according to our measures, is 25 modules and nearly 9 parts.

2578. Palladio gives to the pedestal 2 diameters and nearly two thirds of the height of the column. He adopts the attic, though without rejecting the Ionic base, and makes it half a diameter high, adding to it a small bead, which he comprises in the height of the shaft, which he makes 8 diameters in height. To the architrave, frieze, and cornice, taken together, he assigns a little less than one fifth of the height of the column, including its base and capital, and makes the projection of the cornice equal to its height. The total height of the order, in our measures, is, according to him, 27 modules and nearly 8 parts.

2579. Serlio, in this order more than any of the others, varies from Vitruvius. To the pedestal he gives, including base, die, and cymatium, a little more than a third part of the height of the column, with its base and capital. To the shaft of the column he gives 7 diameters, and diminishes it a sixth part of its diameter. His capital is that of Vitruvius, as far as we can understand that master. His mode of constructing the volute differs from other authors. His directions are, that having found the cathetus, which passes through the centre of the eye, it must be divided into eight parts, from the abacus downwards, one whereof is to be the size of the eye of the volute, four remain above the eye, and three below that part comprised below the eye. The cathetus is then divided into six parts, properly numbered by figures from 1 to 6. With one point of the compasses in 1, and the other extended to the fillet of the volute, he describes a semicircle, and so on with semicircles consecutively from 2 to 6, which will ultimately fall into the eye of the volute. We cannot speak in high terms of Serlio's method, and therefore have thought it unnecessary to accompany the description with a figure. It is rather a clumsy method, and we fear, if exhibited in a figure, would not satisfy our readers of its elegance. The height of his architrave, frieze, and cornice together is a little less than a fourth part of the height of the column, including the base and capital. The whole height of his order, in our measures, is 25 modules and 6 parts.

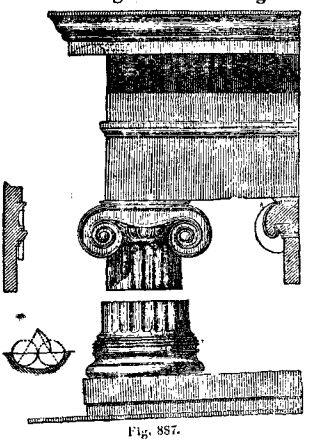

Fig. 887.

2580. Scamozzi directs that the pedestal shall be with its base and cornice two diameters and a half of the column. He uses the attic base, and, like Palladio, gives an astragal above the upper torus. To the shaft of the column he assigns a height of little less than 8 diameters, and makes its diminution a sixth part of the diameter. He adopts the angular capital, something like the example of that in the temple of Fortuna Virilis. The height of his architrave, frieze, and cornice is a little less than a fifth part of the height of the column, with its base and capital. The total height of his order, in our measures, is 26 modules.

2581. The principal examples of the Grecian Ionic are in the temples of Minerva Polias, of Erectheus, and the aqueduct of Hadrian, at Athens; in the temple of Minerva Polias at Priene; of Bacchus at

Teos; of Apollo Didymæus at Miletus; and of the small temple on the Ilyssus, near Athens, whereof in *fig.* 887. the profile is given, and below, a table of the heights and projections of the parts. It is to be observed, that in the Grecian Ionic volute the fillet of the spiral is continued along the face of the abacus, whilst in the Roman examples it rises from behind the ovolo. Some of the Athenian examples exhibit a neck below the echinus, decorated with flowers and plants. The entablatures of the early Ionic are usually very simple. The architrave has often only one fascia, the frieze is generally plain, and the cornice is composed of few parts. In Book I. Chap. II. (153, *et seq.*) we have already examined the parts of the Grecian Ionic, and thereto refer the reader.

Table of the Parts of the Grecian Ionic in the Temple on the Ilyssus.

	Fillet	0·450	23·640
	Torus	5·760	24·960
	Plinth	11·880	26·520

The height from the top of the echinus to the centre of the eye of the volute is 15·72 parts. Total projection of the volute from axis of column, 27·90. The flutes are elliptical on plan (*fig.* 887.), and the distance between axes of columns, 6 mod., 3·24 pts.

2581*a*. An Ionic capital from the celebrated Temple of Diana, at Ephesus, can now be seen at the British Museum, having been recovered during the explorations made in 1872, by Mr. J. T. Wood. The shaft was 6 feet 1 in. diam., and a part of its base was found *in situ*.

SECT. VI.

THE CORINTHIAN ORDER.

2582. For the Corinthian order, we must seek examples rather in Rome than in any part of Greece. The portico at Athens, and the arch of Hadrian at Athens, do not furnish us with specimens of art comparable with the three columns in the Campo Vaccino, belonging, as is generally supposed, to the temple of Jupiter Stator. Those in the temple near Mylassa, and the Incantata, as it is called, at Salonica, do not satisfy the artist, as compared with the examples in the remains of the temple of Mars Ultor at Rome, the temple of Vesta at Tivoli, and others, for which the reader may refer to Desgodetz.

2583. The reader is again here reminded that the module or semidiameter is to be

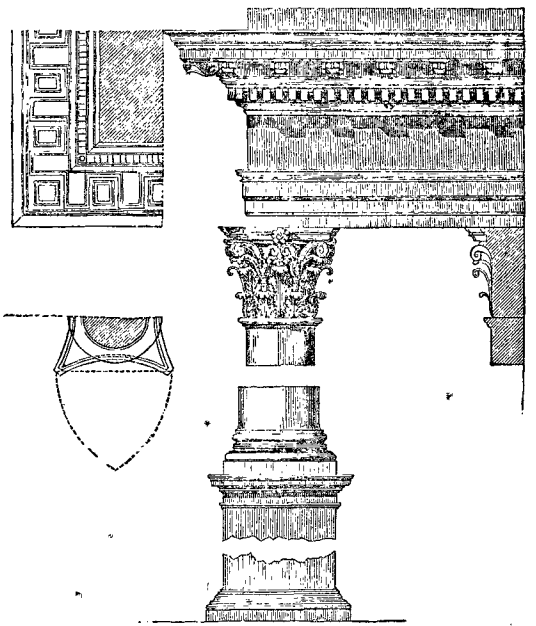

Fig. 888.

divided into eighteen parts. In *fig.* 888. is a representation of the Corinthian order, whose measures are given in the following table:—

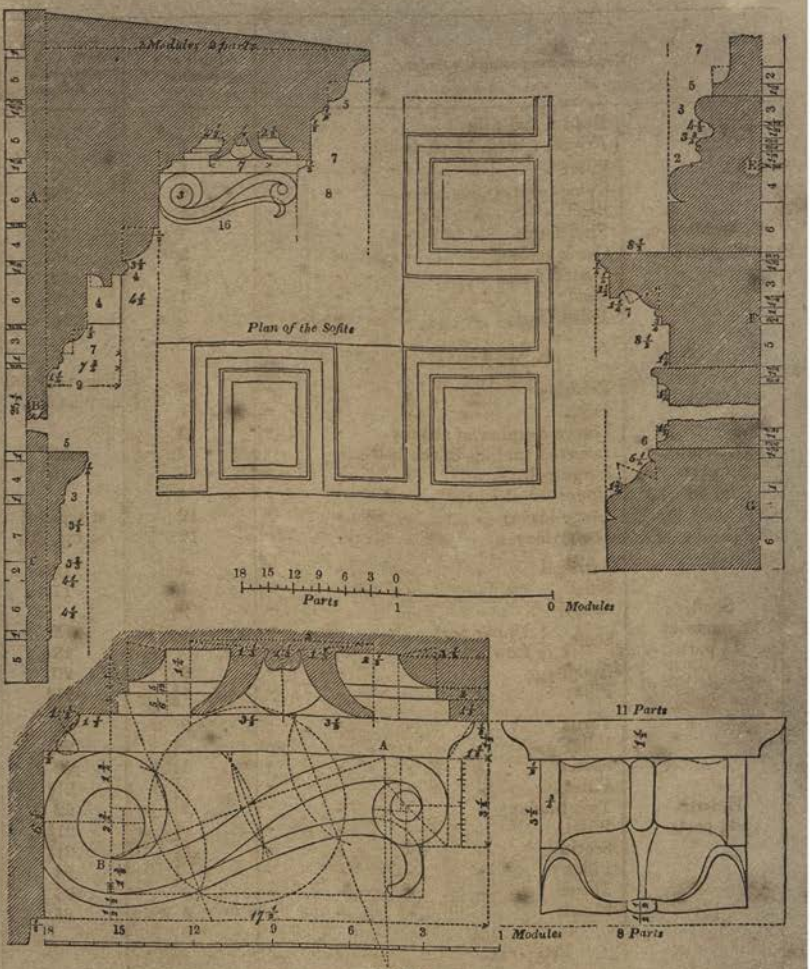

Fig. 889.

2584. *Fig.* 889. shows the details of the entablature, &c. and also the profile and front of the Corinthian modillion to a larger scale. On the profile is shown the caisson or sunk panel on the sofite of the corona. The height is six parts, and the projection sixteen. As seen in the figure, a distance equal to three parts and a half is taken for the height of the smaller volute, and on this distance a scale of sixteen equal parts is made; the figure shows the dimensions to be given to the small squares, whose angles serve as centres to describe the curves. Having drawn the line AB, it is divided into four equal parts by lines perpendicular to it, which, meeting vertical lines from A and B, give the points, which serve as centres for striking the curve of the modillions. The acanthus leaf which supports it, as well as the curves which form the profile of the roses in the caisson, are also struck by compasses.

2285. In *fig.* 890., which exhibits the method of drawing the Corinthian capital, one half of the plan shows the capital in plan, and the other half of it laid down diagonally. Having drawn the axis of the plan correspondent to the axis of the elevation of the capital, with a radius equal to two modules, describe a circle, which divide into sixteen equal parts. Their lines of division will each correspond to the centre of each leaf. The vase of the capital is determined by a circle whose radius is 14½ parts. The figure shows the circles which bound the leaves upwards on the vase.

2586. The elevation shows the heights whereon are carried the projections of the plan.

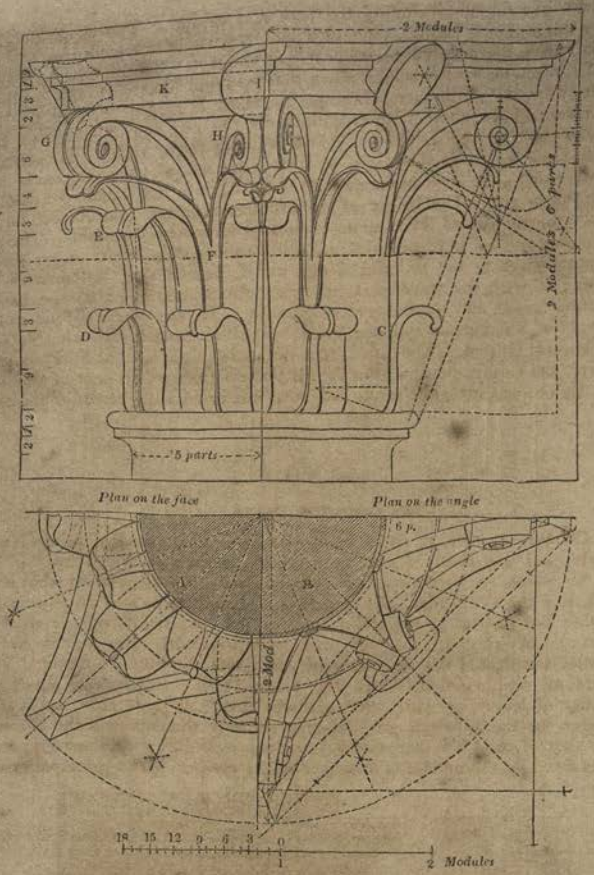

Fig. 890.

Above the leaves come the sixteen volutes, whereof the eight larger ones support the four angles of the abacus, and the eight smaller ones support the flowers which decorate the middle of the abacus. The volutes seen in profile may be drawn geometrically with the compasses, but they are always more agreeable and easy when drawn by the eye with a hand which feels the contours.

The different parts of the capital are as follow: A, plan of the leaves and abacus; B, plan of the larger and smaller volutes; C, the vase or body of the capital; D, the first tier of leaves; E, the second tier of leaves; F, the caulicolus; G, the larger volute; H, the smaller volute; I, the flower; K, the abacus; L, the lip of the vase.

2587. Vitruvius is scanty in the information he gives on the Corinthian order, and what he says respecting it relates more to the origin of the capital and the like than to the proportions of the detail. He makes the capital only 1 diameter high, and then forms upon the plan a diagonal 2 diameters long, by means whereof the four faces are equal according to the length of the arc, whose curve will be the ninth part in length and its height the seventh part of the capital. He forms the order with a pedestal, with base and cornice, as Daniel Barbaro would have it. The whole height given to it in our measures is about 27 modules and 2 parts.

2588. Palladio uses the pedestal with its ordinary subdivisions, making it between a third and fourth part of the height of the column, including its base and capital. To the base he gives 1 module, the shaft of the column a little less than 8 diameters, and places twenty-four flutes upon it, which two thirds downwards are channelled, and on the other or lower third neatly fitted with convex pieces of segments of cylinders called *cablings*. He makes the capital 1 diameter and a sixth in height, giving it two tiers of leaves, caulicoli, and abacus. To the architrave, frieze, and cornice he assigns a little less

than a fifth part of the column, including the base and capital. The whole height given to the order by this author is about 27 modules and 10 parts of our measures.

2589. Serlio makes his pedestal pretty nearly as the rest. To the base of the column he assigns half a diameter for the height, when that is about level with the eye, but when much above it he directs all the members to be increased in height accordingly, as where one order is placed above another, he recommends the number of parts to be diminished. To the shaft of the column he gives a little more than 7 diameters, and to the capital the same height as that given by Vitruvius, whom, nevertheless, he considers in error, or rather that some error has crept into the text, and that the abacus ought not to be included in the height. The height of the architrave, frieze, and cornice he makes a little less than a fourth part of the column, including its base and capital. The whole of the order, according to him, is 28 modules and a little more than 1 part of our measures.

2590. Scamozzi gives to the pedestal of this order the height of 3 diameters and one third, composing it with the usual parts of base, die, and cornice; to the base of the column the same height and mouldings as Palladio. To the shaft of the column he assigns the height of 8 diameters and one third, and diminishes it on each side an eighth part of its thickness at bottom. The capital is of the same height as that by Palladio. The architrave, frieze, and cornice he directs to be a little less than a fifth part of the height of the column. By our measures the whole height of his order is 30 modules and 20 parts.

SECT. VII.

THE COMPOSITE ORDER.

2591. The Composite order, as its name imports, is a compound of others, the Corinthian and Ionic, and was received into the regular number of orders by the Romans. Philander, in his notes on Vitruvius, has described its proportions and character. Its capital consists, like the Corinthian, of two ranges of acanthus leaves distributed over the surface of a vase, but instead of the stalks or branches, the shoots appear small and as though flowering, adhering to the vase and rounding with the capital towards its middle. A fillet terminates the vase upwards, and over the fillet an astragal is placed, and above that an echinus, from which the volutes roll themselves to meet the tops of the upper tier of leaves, on which they seem to rest. A large acanthus leaf is bent above the volutes, for the apparent purpose of sustaining the corner of the abacus, which is dissimilar to that of the Corinthian order, inasmuch as the flower is not supported by a stalk seemingly fixed on the middle of each face of the abacus. The principal examples of

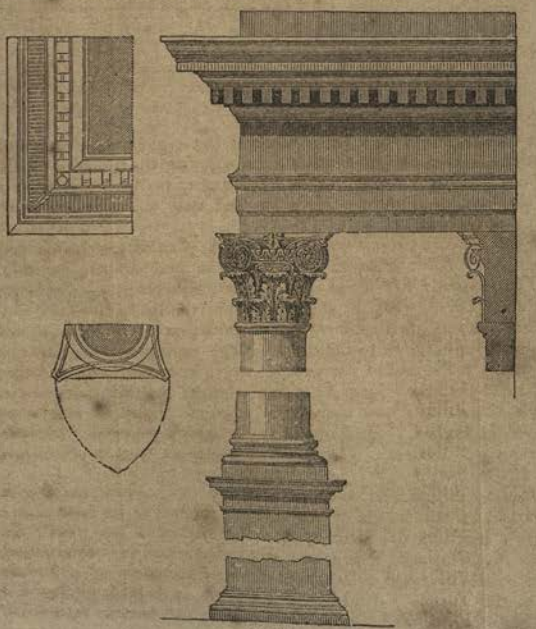

Fig. 891.

the order are at Rome, in the temple of Bacchus, the arches of Septimius Severus, of the Goldsmiths, and of Titus; also in the baths of Diocletian.

2592. *Fig.* 891. (see preceding page) is a representation of Vignola's profile of the order. Its measures are subjoined in the following table: —

Members composing the Order.		Heights in Parts of a Module.	Projections from Axis in Parts of a Module.
	ENTABLATURE.		
A, Cornice, 36 parts.	Fillet of cornice	1½	51
	Cyma recta	5	51
	Fillet	1	46
	Cyma reversa	2	45½
	Bead	1	43¾
	Corona	5	43
	Cyma under the corona	1½	41
	Fillet	1	33
	Cyma reversa	4	32½
	Fillet of the dentils	⅓	28
	Dentils	7½	29

	Inverted cyma reversa	3	$30\frac{1}{4}$
	Fillet	1	$31\frac{1}{4}$
	Torus	3	33
	Plinth	4	33

2593. The flutes in this order are separated by a fillet between them, and are, when used, twenty-four in number.

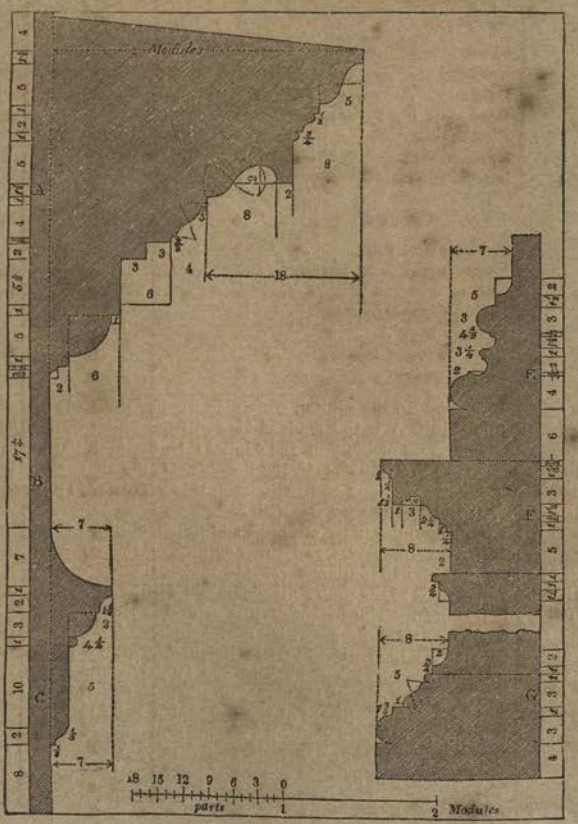

Fig. 892.

2594. *Fig.* 892. (see preceding page) shows the parts of the entablature, base, and pedestal to a larger scale, and *fig.* 893. gives, similarly, a more intelligible, because larger, represent-

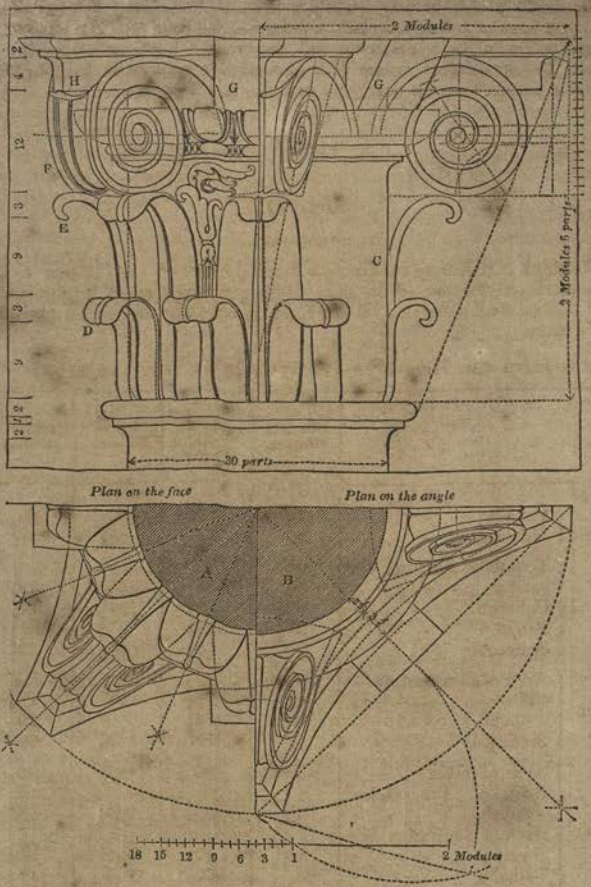

Fig. 893.

ation of the mode of setting up the capital, which, as we have already observed, has only eight volutes. In this figure A is the plan, as viewed frontwise; B, that of the capital viewed diagonally; C, the vase or body of the capital; D, the first tier of leaves; E, the second tier of the same; F, the volutes; G, the flower; H, the abacus.

2595. Vitruvius has not given any instructions on this order; we are therefore obliged to begin our parallel, as in the other orders, with —

2596. Palladio, whose examples of it are light and much decorated. To the pedestal's height this master assigns 3 diameters and three eighths of the column, adding to it a lower plinth of the height of half a diameter. He makes the base of the column half a diameter in height, and assigns to the shaft 8 diameters and a little more than one fourth, and cuts on it twenty-four flutes. The height of this capital is 1 diameter and a sixth, his volutes being very similar to those he prescribes for his Ionic. The architrave, frieze, and cornice he makes a little less than a fifth part of the height of the column. The whole height of his profile in our measures is 30 modules and 12 parts.

2597. Serlio seems to have founded his profile of this order upon the example in the Coliseum at Rome. He makes the height of the pedestal a little less than 4 diameters of the column. To the shaft of the column he assigns 8 diameters and a half. To the height of the capital he gives 1 diameter, differing therein from his profile of the Corinthian order in the disposition of the volutes and leaves. His entablature, which is a little less in height than one fourth of the column, he divides into three equal parts for the

architrave, frieze, and cornice. The total height of his profile in our measures is 32 modules and 9 parts, being much higher than that of Palladio.

2598. Scamozzi's profile greatly resembles that of Palladio. His pedestal is 3 diameters, and the base of his column half a diameter in height. The shaft of his column without base or capital, is 8 diameters and one twelfth high, and the capital 1 diameter and a sixth. The entablature is one fifth part of the column in height, and the whole of the profile in our measures is nearly 29 modules and 7 parts.

SECT. VIII.

PEDESTALS.

2599. We think it necessary to devote a small portion of our labour to the consideration of pedestals, on account of the great difference which exists in the examples of the orders, and this we shall place in a tabular form, previous to the general remarks it will be necessary to make.

TABLE SHOWING THE HEIGHT OF PEDESTALS IN ANCIENT AND MODERN WORKS.

		Plinth in Minutes.	Mouldings above Plinth in Minutes.	Die in Minutes.	Cornice in Minutes.	Total Height in Minutes.
Doric	Palladio	26	14	80	20	140
	Scamozzi	30	15	68 4/7	22 1/2	136 1/14
Ionic	Temple of Fortuna Virilis	44	19 3/4	93 3/4	23 1/4	180 3/4
	Coliseum	33 1/4	9 1/2	81 5/6	17	141 1/2
	Palladio	28 2/3	14 1/3	97 3/4	21 1/2	162 1/4
	Scamozzi	30	15	82 1/2	22 1/2	150
Corinthian	Arch of Constantine	17 1/2	29	153	29 1/2	228
	Coliseum	23	11 1/3	78	19 1/4	131 3/4
	Palladio	23 1/2	14 1/3	93	19	150
	Scamozzi	30	15	132 1/2	22 1/2	200
Composite	Arch of Titus	55	30	141	29	255
	Arch of the Goldsmiths	46	25 1/4	144 1/2	25 1/4	241
	Arch of Septimius Severus	30	30 5/6	140 1/2	29 5/6	182 1/3
	Palladio	33	17	133	17	200
	Scamozzi	30	15	112 1/2	22 1/2	180

2600. The minutes used in the above table are each equal to one sixtieth of the diameter of the shaft.

2601. Whether the pedestal is to be considered a component part of an order is of little importance. There are so many cases that arise in designing a building, in which it cannot be dispensed with, that we think it useful to connect it with the column and entablature, and have consequently done so in the examples already given of the several orders. Vitruvius, in the Doric, Corinthian, and Tuscan orders, makes no mention of pedestals, and in the Ionic order he seems to consider them rather as a necessary part in the construction of a temple than as belonging to the order itself.

2602. A pedestal consists properly of three parts, the base, the die, and the cornice. "Some authors," says Chambers, "are very averse to pedestals, and compare a column raised on a pedestal to a man mounted on stilts, imagining they were first introduced merely through necessity, and for want of columns of a sufficient length. "It is indeed true," he continues, "that the ancients often made use of artifices to lengthen their columns, as appears by some that are in the baptistery of Constantine at Rome; the shafts of which, being too short for the building, were lengthened and joined to their bases by an undulated sweep, adorned with acanthus leaves; and the same expedient has been made use of in some fragments which were discovered a few years ago at Nismes, contiguous to the temple of Diana. Nevertheless, it doth not seem proper to comprehend pedestals in

the number of these artifices, since there are many occasions on which they are evidently necessary, and some in which the order, were it not so raised, would lose much of its beautiful appearance. Thus, within our churches, if the columns supporting the vault were placed immediately on the ground, the seats would hide their bases and a good part of their shafts; and in the theatres of the ancients, if the columns of the scene had been placed immediately on the stage, the actors would have hid a considerable part of them from the audience; for which reason it was usual to raise them on very high pedestals, as was likewise necessary in their triumphal arches; and in most of their temples the columns were placed on a basement or continued pedestal (*stylobata*), that so the whole might be exposed to view, notwithstanding the crowds of people with which these places were frequently surrounded. And the same reason will authorise the same practice in our churches, theatres, courts of justice, or other public buildings where crowds frequently assemble. In interior decorations, where, generally speaking, grandeur of style is not to be aimed at, a pedestal diminishes the parts of the order, which otherwise might appear too clumsy; and has the farther advantage of placing the columns in a more favourable view, by raising their base nearer to the level of the spectator's eye. And in a second order of arcades there is no avoiding pedestals, as without them it is impossible to give the arches any tolerable proportion. Sometimes, too, the situation makes it necessary to employ pedestals, an instance of which there is in the Luxembourg at Paris; where, the body of the building standing on higher ground than the wings, the architect was obliged to raise the first order of the wings on a pedestal, to bring it upon a level with that of the body or *corps de logis* of the building, which stands immediately on the pavement."

2603. The dies of pedestals are occasionally decorated with tablets or with sunk panels whose margins are moulded; but, generally speaking, such practices are to be avoided. In very large pedestals the surface may be thus broken, as in single monumental columns, which, at best, are but paltry substitutes for originality. Habit has reconciled us to view with pleasure the Trajan and Antonine columns, the monument of London, and the column of Napoleon in the Place Vendôme at Paris, in each of which the pedestals are ornamented in some way or other, so as to tell in some measure the story of the person in whose honour they were erected, or, as in the basso-relievo of the London column, the event which it records. But care must be taken when inscriptions are used to preserve a rigid adherence to truth, and not to perpetuate a lie, as was the case in the monument just named, against a most worthy portion of the people of the British empire.

2604. As respects the employment of pedestals, we should advise the student, except under very extraordinary circumstances, to avoid the use of them under columns which are placed at a distance from the main walls of an edifice, as, for example, in porches, peristyles, or porticoes, — a vice most prevalent in the Elizabethan architecture, or rather the cinque-cento period, which the people of this day are attempting with all its absurdities to revive. Here we must again quote our author, Sir William Chambers, whose excellent work we have used above, and on which we shall continue to draw largely. "With regard," he says, "to the application of pedestals, it must be observed, that when columns are entirely detached, and at a considerable distance from the wall, and when they are employed to form porches, peristyles, or porticoes, they should never be placed on detached pedestals, as they are in some of Scamozzi's designs, in the temple of Scisi (Assisi) mentioned by Palladio, and at Lord Archer's house, now Lowe's hotel, in Covent Garden; for then they indeed may be compared to men mounted on stilts, as they have a very weak and tottering appearance. In compositions of this kind, it is generally best to place the columns immediately on the pavement, which may be either raised on a continued solid basement, or be ascended to by a flight of fronting steps, as at St. Paul's and at St. George's Bloomsbury; but if it be absolutely necessary to have a fence in the intercolumniations, as in the case of bridges or other buildings on the water, or in a second order, the columns may then, in very large buildings, be raised on a continued plinth, as the upper order of the western porch of St. Paul's, which in such case will be sufficiently high: and in smaller buildings, wherever it may not be convenient or proper to place a balustrade between the shafts, the columns may be placed on a continued pedestal, as they are in Palladio's designs for Signor Cornaro's house at Piombino, and at the villa Arsic near Vicenza, another beautiful building of the same master." The same author continues: "The base and cornice of these pedestals must run in a straight line on the outside throughout, but the dies are made no broader than the plinths of the columns, the intervals between them being filled with balusters, which is both really and apparently lighter than if the whole pedestal were a continued solid." The author quoted then proceeds to caution the student against the employment of triangular, circular, and polygonal pedestals, and such as are swelled and have their die in the form of a baluster, or are surrounded by cinctures.

These extravagances were rife in the age of Louis XV., but notwithstanding the zeal of the jobbing upholsterers and decorators of the present day, who are the curse of all architectural art, we hope they will never be permanently revived in this country, though their introduction has already proceeded to a considerable extent

SECT. IX.

INTERCOLUMNIATIONS.

2605. An intercolumniation is the clear distance between two columns measured at the lower diameter of their shafts. This distance must depend principally on the order employed: in the Tuscan, for example, the nature of its composition allows a greater width between columns than would be admissible in the Corinthian order, independent of what has already been stated in Sect. II. (2524, *et seq.*) in respect of supports and loading; and this because of the enrichments of the several orders requiring that they should take their departures (to use a phrase borrowed from another science) from the axes of their respective columns. The ancient names (which are still preserved) of the different intercolumniations are described by Vitruvius in his second and fourth books. They are — the *pycnostyle*, wherein the space between the columns is 1 diameter and a half, as its etymology from πυκνος and στυλος imports (thick in columns), an intercolumniation used only in the Ionic and Corinthian orders; the *systyle* (συστυλος, with columns a little more apart), wherein the interval between the columns is a little greater; the *eustyle* (ευστυλος, or well-contrived interval), wherein the intercolumniation is of 2 diameters and a quarter; the *diastyle* (διαστυλος, with a more extended interval between the columns), having an intercolumniation of 3 diameters; and the *aræostyle* (αραιοστυλος, with few columns), wherein the interval is 4 diameters. In the Doric order the triglyphs necessarily regulate the intercolumniations, inasmuch as the triglyph should fall over the axis of the column; hence the intercolumniations in this order are either systyle monotriglyph (that is, with a single triglyph in the intercolumniation), or 2½ diameter; diastyle, or of 2¾ diameters; or aræostyle, which will make the interval 4 diameters, as will be immediately understood on reference to *fig.* 894.; wherein A is the systyle monotriglyph intercolumniation of 3 modules; B, that of the diastyle, or 6 modules; and C, the aræostyle, or of 8 modules. The intercolumniation marked D serves for the application of coupled columns, wherein the rule seems necessarily to be that the space between the columns may be increased, so that the requisite number of supports according to the order and intercolumniation is preserved.

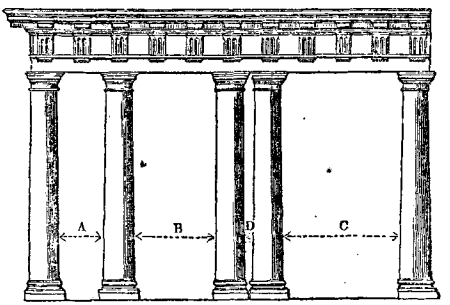

Fig. 894.

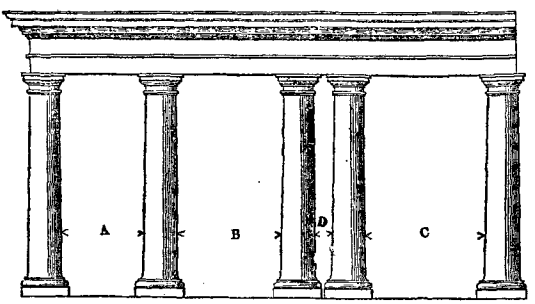

Fig. 895.

2606. The intervals of the Tuscan order are indicated in *fig.* 895., wherein A shows the intercolumniation called eustyle of 4½ modules; B, the diastyle of 6 modules; and C, the aræostyle of 8. D, of 1 module, is the space of coupled columns.

The intercolumniations in this order are scarcely susceptible of rules other than those we have indicated in our previous discussion on the orders generally in Sect. II. (2523, *et seq.*), wherein we have entered on the subject at such length that we refrain from saying more in this place. We may, however, observe, that the application of the principles there mentioned are so intimately connected with this section, that the separation of one from the other would destroy all our scheme for keeping the student in the right path. Hereafter the principles in question will be applied to and tested on arcades.

2607. In *fig.* 896., of Ionic intercolumniations, A is the eustyle arrangement; B, that of the diastyle; C, that of the aræostyle; and D, that of coupled columns.

Fig. 896.

2608. *Fig.* 897. is a similar application of the intercolumniations to the Corinthian order, wherein also A exhibits the eustyle; B, the diastyle; and C, the aræostyle intervals: D also showing the space used of 1 module for coupled columns.

Fig. 897.

2609. Sir William Chambers, for whose observations we have much respect, — and, indeed, to whose valuable labours we acknowledge ourselves much indebted, — seems to have had a distant glimpse of the doctrine of equal weights and supports, but knew not exactly how to justify his notions on the subject. He therefore avoids the main question by attributing the pycnostyle intercolumniation rather to necessity than choice; observing, that "as the architraves were composed of single stones or blocks of marble, extending from the axis of one column to that of another, it would have been difficult to find blocks of a sufficient length for diastyle intervals in large buildings." But this is a reason altogether unsatisfactory, inasmuch as we know that they were sufficiently masters of masonry to have conquered any such difficulty. We are much more inclined t agree with him when he says (always, however, reverting to the principle of equal support and weights), "With regard to the aræostyle and Tuscan intercolumniations, they are b much too wide either for beauty or strength, and can only be used in structures wher the architraves are of wood, and where convenience and economy take place of all othe considerations: nor is the diastyle sufficiently solid in large compositions." These consider ations, however, may be always safely referred to the doctrines laid down in Section II of this Chapter, already alluded to; and, indeed, that reference is justified by the instruc tions of Vitruvius in the second chapter of his third book, wherein he directs that th thickness of the column should be augmented in an enlarged intercolumniation: as, fo example, supposing the diameter of a column in the pycnostyle species to be taken on tenth of the height, it should in an aræostyle be one eighth; arguing, that if in an aræostyl the thickness of the columns exceed not a ninth or tenth part of their height, they appea too slender, and in the pycnostyle species the column at one eighth of its height is clums and unpleasant in appearance. Upon this passage Chambers observes, "that the intentio of Vitruvius was good, but the means by which he attempts to compass it insufficien His design was to strengthen the supports in proportion as the intervals between the were enlarged; yet according to the method proposed by him this cannot be effecte since one necessary consequence of augmenting the diameter of the column is enlarging t intercolumniation proportionably. Palladio and Scamozzi have however admitted th precept as literally just, and by their manner of applying it have been guilty of very considerable absurdity." We are not at all inclined to admit the truth of the opinion of Chambers; for, again reverting to the doctrine of the supports and loading, which was unknown to him, it is to be remembered that increase in the space of the intercolumniation immediately involves increase of weight in the load or entablature, and therefore seems to demand increase of diameter to the supports. Palladio and Scamozzi were not therefore guilty of the absurdity laid to their charge.

2610. Among the other reasons for our adopting the practice of Vignola is that he has observed so much uniformity in his intercolumniations, except of the Doric order, wherein the triglyphs prevent it, aware as we are that the practice has by many able writers been much condemned. Chambers even says that his practice in this respect is "preferable to any other, as it answers perfectly the intention of Vitruvius, preserves the character of each order, and maintains in all of them an equal degree of real solidity."

2611. With the exception of the Doric order, wherein the most perfect arrangement of the detail results from the interval produced by the ditriglyph, there can be no doubt that, abstractedly considered, the diastyle and eustyle intercolumniations are very convenient in use, and may be employed on most occasions, except, as just mentioned, in the Doric order.

2612. In setting out the intervals between columns especial care must be taken that the centres of modillions, dentils, and other ornaments in the entablature fall over the axes of the columns. It is on this account that Vignola gives about two diameters and a third to the intervals in all the orders except the Doric, instead of two diameters and a quarter, as required by Vitruvius; an alteration which removes the difficulty and greatly simplifies the rules.

2613. Cases from many circumstances often occur where greater intercolumniations than the eustyle and diastyle are too narrow for use, and the moderns, headed by Perrault, have adopted an interval which that master has called aræosystyle. This disposition is obtained without infringing on the law of weights and supports, to which we have already so often alluded. In it the columns are *coupled*, as shown in the preceding figures, the interval being formed by two systyle intercolumniations, the column separating them being, as Chambers observes, "approached towards one of those at the extremities, sufficient room being only left between them for the projection of the capitals, so that the great space is 3½ diameters wide, and the small one only half a diameter." One of the finest examples of this practice is to be seen in the façade of the Louvre, (see *fig.* 176.) which in many respects must be considered as the finest of modern buildings. The objections of Blondel to the practice are not without some weight, but the principal one is the extra expense incurred by it; for certain it is that it requires nearly double the number of columns wanted in the diastyle, besides which it cannot be denied that it causes considerable irregularities in the entablatures of the Doric, Corinthian, and Composite orders, which, however, are not apparent in the other two. It is, nevertheless, so useful in cases of difficulty which constantly arise, that we should be sorry to exclude the practice altogether, though we cannot recommend it for unlimited adoption.

2614. A great many expedients have been employed to obviate the irregularity of the modillions in the Corinthian and Composite orders, arising from the grouping of columns. We, on this head, agree with Chambers, whose instructions we subjoin in his own words: "The simplest and best manner of proceeding is to observe a regular distribution in the entablature, without any alteration in its measures, beginning at the two extremities of the building, by which method the modillions will answer to the middle of every other column, and be so near the middle of the intermediate ones, that the difference will not easily be perceivable. The only inconvenience arising from this practice is, that the three central intercolumniations of the composition will be broader by one third of a module than is necessary for eleven modillions: but this is a very trifling difference, easily divided and rendered imperceptible if the extent be anything considerable." In the Doric order, the grouping of columns is not so easily managed, and therein our author recommends the expedient employed by Palladio, in the Palazzo Chiericato, and in the Basilica at Vicenza. In the last-named, the coupled columns are only 21 minutes apart, thus making the space between the axes 2 modules and 21 minutes, that is, 6 minutes beyond the breadth of a regular metope, and 2 half-triglyphs. To conceal the excess, the triglyphs are 31 minutes broad, and their centres are carried 1 minute within the axis of the column, and the metope is 3 minutes broader than the others. These small differences are not perceptible without a very critical and close examination of the distribution. In this arrangement the attic base of Palladio should be employed, because of its small projection, and the larger intercolumniation must be aræostyle.

2615. Intercolumniations should be preserved of equal width in all peristyles, galleries, porticoes, and the like; but in loggias or porches, the middle interval may be wider than the others by a triglyph, a modillion or two, and a few dentils, that is, if there be no coupled columns at the angles nor groupings with pilasters, in which cases all the other intervals should be of the same dimensions. It has been observed by Blondel, that on occasions where several rows of columns are used, as, for instance, in the curved colonnades of the piazza of St. Peter's, the columns ought as much as possible to be in straight lines, because otherwise the arrangement can only be understood by viewing it from the centre of the figure employed. The observation is well worth the student's consideration, for the resulting effect of a departure from this rule, as Chambers has properly observed, is "nothing but confusion to the spectator's eye from every point of view." The same author condemns, and with justice, though in a smaller degree, the use of "engaged pilasters or half columns placed behind the detached columns of single, circular, oval, or polygonal peristyles, as may be seen in those of Burlington House. Wherefore," he says, "in buildings of that kind, it will perhaps be best to decorate the back wall of the peristyle with windows or niches only." We can hardly suppose it here necessary to caution the student against the use of intercolumniations without reference to the absolute

size of them; they must not be less than three feet even in small buildings, because, as Sir William Chambers seriously says, "there is not room for a *fat* person to pass between them."

2616. Before leaving the subject which has furnished the preceding remarks on intercolumniations, we most earnestly recommend to the student the re-perusal of Section II. of this Book. The intervals between the columns have, in this section, been considered more with regard to the laws resulting from the distribution of the subordinate parts, than with relation to the weights and supports, which seem to have regulated the ancient practice: but this distribution should not prevent the application generally of the principle, which may without difficulty, as we know from our own experience, be so brought to bear upon it as to produce the most satisfactory results. We may be perhaps accused of bringing a fine art under mechanical laws, and reducing refinement to rules. We regret that we cannot bind the professor by more stringent regulations. It is certain that, having in this respect carried the point to its utmost limit, there will still be ample opportunity left for him to snatch that grace, beyond the reach of art, with the neglect whereof the critics are wont so much to taunt the artist in every branch.

Sect. X.

ARCADES AND ARCHES.

2617. An arcade, or series of arches, is perhaps one of the most beautiful objects attached to the buildings of a city which architecture affords. The utility, moreover, of arcades in some climates, for shelter from rain and heat, is obvious; but in this dark climate, the inconveniences resulting from the obstruction to light which they offer, seems to preclude their use in the cities of England. About public buildings, however, where the want of light is of no importance to the lower story, as in theatres, courts of law, churches, and places of public amusement, and in large country seats, their introduction is often the source of great beauty, when fitly placed.

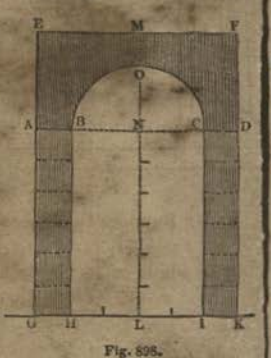

Fig. 898.

2618. In a previous section (2524.) we have spoken of Lebrun's theory of an equality between the weights and supports in decorative architecture: we shall here return to the subject, as applied to arcades, though the analogy is not, perhaps, strictly in point, because of the dissimilarity of an arch to a straight lintel. In *fig.* 898. the hatched part AEMFDCOB is the load, and ABGH, CDIK the supports. The line GK is divided into six parts, which serve as a scale to the diagram, the opening HI being four of them, the height BH six, NO two, and OM one. From the exact quadrature of the circle being unknown, it is impossible to measure with strict accuracy the surface BOC, which is necessary for finding by subtraction the surface AEMFDCOB; but using the common method, we have

$$AD \times AE - \frac{BC^2 \times 7854}{2} = \text{to that surface; or, in figures,}$$

$$6 \times 3 - \frac{4 \times 4 \times 7854}{2} = 11{\cdot}72.$$

Now the suports will be $IK \times IC \times 2$ (the two piers) $= 1 \times 6 \times 2 = 12{\cdot}00$ the piers; or, in figures,

That is, in the diagram the load is very nearly equal to the supports, and would have been found quite so, if we could have more accurately measured the circle, or had with greater nicety constructed it. But we have here, where strict mathematical precision is not our object, a sufficient ground for the observations which follow, and which, if not founded on something more than speculation, form a series of very singular accidents. We have chosen to illustrate the matter by an investigation of the examples of arcades by Vignola, because we have thought his orders and arcades of a higher finish than those of any other master; but testing the hypothesis, which we intend to carry out by examples from Palladio, Scamozzi, and the other great masters of our art, not contemplated by Lebrun, the small differences, instead of throwing a doubt upon, seem to confirm it.

2619. In *fig.* 898. we will now carry, therefore, the consideration of the weights and supports a step further than Lebrun, by comparing them with the void space they surround, that is, the opening HBOCI; and here we have the rectangle $HBCI = HB \times HI$, that is, $6 \times 4 = 24$, and the semicircle BOC equal, as above, to $\frac{4 \times 4 \times 7854}{2} = 6{\cdot}28$. Then $24 + 6{\cdot}28 = 30{\cdot}28$ is the area of the whole void, and the weight and support being $11{\cdot}72 +$

12=23·72, are a little more than two thirds the areas of the whole void; a proportion which, if we are to rely on the approval of ages in its application, will be found near the limits of what is beautiful.

2620. We shall now refer to the examples of Vignola alluded to; but to save the repetition of figures in their numbers, as referred to, each case is supposed in what immediately follows as unconnected with the entablatures which they exhibit, it being our intention to take those into separate consideration.

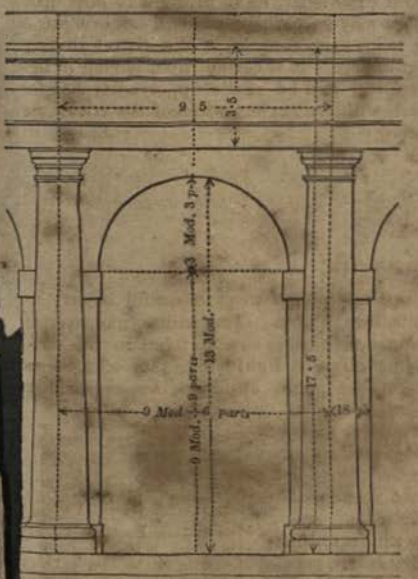

Fig. 899.

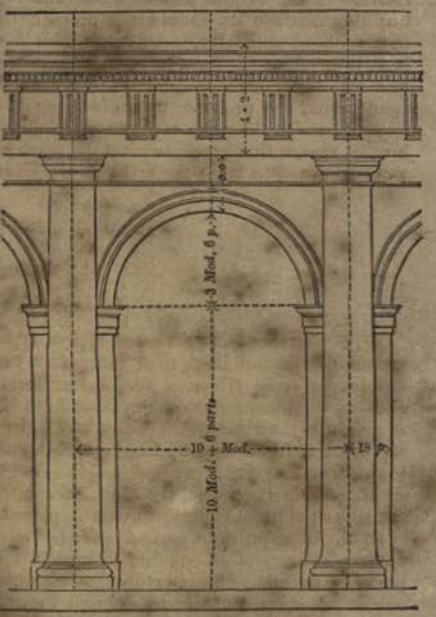

Fig. 900.

2621. Suppose the Tuscan example (*fig.* 899.) without an entablature, we have the

Supports, $9·75 \times 3$	=	29·25
The whole of rectangle above them, $4·25 \times 9·5$	=	40·375
Less semi-arch, $\frac{6·5 \times 6·5 \times ·7854}{2}$	=	16·6
		23·775
		53·025 solid parts.

The area of the void is $16·6 + \overline{9·75 \times 6·5} = 79·97$, whereof 53·025, the portion of solid parts, is not widely different from two thirds.

In Vignola's Doric example, (*fig.* 900.), again without the entablature, we have

Supports, $10·5 \times 3$	=	31·50
The whole rectangle above them, $5·5 \times 10·0$	=	55·00
Less semi-arch, $\frac{7 \times 7 \times ·7854}{2}$	=	19·24
		35·76
		67·26 solid parts.

The area of the void is $19·24 + \overline{10·5 \times 7} = 92·74$, whereof 67·26, the portion of solid parts, is not much different from two-thirds.

In the Ionic example (*fig.* 901.), still without considering the entablature, the following will result:—

Supports, $12·64 \times 2·66$	=	33·61
The whole rectangle above them, $10·88 \times 5·2$	=	56·57
Less semi-arch, $\frac{6·4 \times 6·4 \times ·7854}{2}$	=	16·08
		40·49
		74·10 solid parts.

The area of the void is $16·08 + \overline{12·64 \times 7·1} = 105·82$, whereof 74·10, the portion of solid parts, differs little in amount from two thirds of the void.

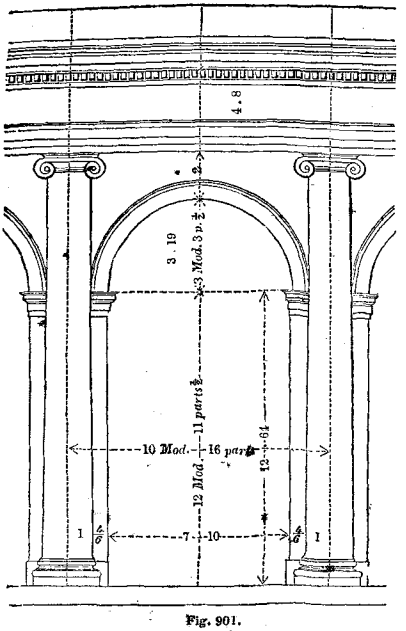

Fig. 901.

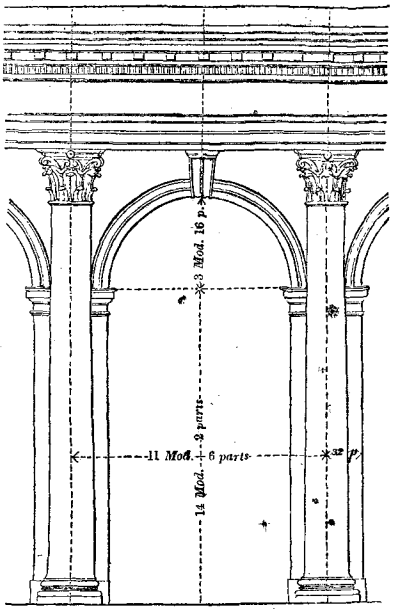

Fig. 902.

In the Corinthian example (*fig.* 902.), not taking into consideration the entablature, the following is the result:—

Supports,	$14{\cdot}11 \times 3{\cdot}55 =$	$50{\cdot}09$
The whole rectangle above them,	$11{\cdot}33 \times 5{\cdot}88 = 66{\cdot}62$	
Less semi-arch,	$\frac{7{\cdot}76 \times 7{\cdot}76 \times {\cdot}7854}{2} = 23{\cdot}65$	
	$= 32{\cdot}97$	
		$83{\cdot}06$ solid parts.

The area of the void is $23{\cdot}65 + \sqrt{14{\cdot}11 \times 7{\cdot}76} = 133{\cdot}15$, whereof 83·06, the portion of solid parts, is somewhat less than two thirds of the void.

2622. The result which flows from the above examination seems to be that, without respect to the entablature, the ratio of the solid part to that of the void is about ·666. Bearing this in mind, we shall next investigate the ratio of the supports and weights, considering the entablature above the arcade as a part of the composition; and still following Vignola, whose examples, as we have above stated, do not so much differ from those of other masters as to make it necessary to examine those of each, we will begin with that architect's Tuscan arcade, without pedestals, exhibited in *fig.* 899. on the preceding page. In this example, from centre to centre of pier,

The whole area, in round numbers,	$17{\cdot}5 \times 9{\cdot}5$	$= 166{\cdot}2$
Area of semi-arch,	$\frac{6{\cdot}5 \times 6{\cdot}5 \times {\cdot}7854}{2} = 16{\cdot}6$	
Rectangle under it,	$9{\cdot}75 \times 6{\cdot}5 = 63{\cdot}3$	
	Total void, therefore,	$= 79{\cdot}9$
		$86{\cdot}3$
Entablature,	$9{\cdot}5 \times 3{\cdot}5$	$= 33{\cdot}2$
Leaves for the supporting parts		$53{\cdot}1$

In this example, therefore, the supporting parts are 53, those supported 33, and the voids 79. The ratio between the solid and void parts = ·9, and the ratio of the supports to the weights is $\frac{33}{53} = {\cdot}62$.

The distance between the axes of the columns is 9 modules and 6 parts; the height of the semi-arch, 3 modules and 3 parts; and between the crown of it and the under side of the architrave is 1 module; the whole height, including entablature, being 17 modules and a half.

2623. Following the same general method, we submit the Doric arcade (*fig.* 900.) without pedestal. Measuring, as before, from centre to centre of piers,

The whole area, in round numbers, 20·2 x 10			=202·0
Area of semi-arch $\frac{7\times7\times\cdot7854}{2}$	=19·2		
Rectangle under it, 10·5 x 7	=73·5		
	Total void, therefore,	=	92·7
			109·3
Entablature, 10 x 4·2			42·0
Leaves for the supporting parts			67·3

In this example, therefore, the supporting parts are 67, those supported 42, and the voids 92. The ratio between the solid and void parts is ·85, and the ratio of the supports to the weights is $\frac{42}{67}$ = ·63.

The distance between the axes of the columns is 10 modules, the height of the semi-arch is 3 modules and 6 parts, and between the crown of it and the underside of the architrave is 2 modules; the whole height, including the entablature, being 20 modules 3½ parts.

2624. The Ionic arcade, without pedestal, is shown in *fig.* 901. The measurements, as above, from centre to centre of pier,

The whole area, 22·64 x 10·88 in round numbers			=246·3
Area of semi-arch, $\frac{6\cdot4\times6\cdot4\times\cdot7854}{2}$	=16·1		
Rectangle under it, 12·64 x 7·1	=89·7		
	Total void, therefore,	=105·8	
			140·5
Entablature, 10·88 x 4·8			52·2
Leaves for the supporting parts			88·3

Hence, in the example, the supporting parts are 88, those supported 52, and the voids 105; so that the ratio of the voids to the solids, in this order, is ·8, and the ratio of the supports to the weights does not materially differ from the other orders, being $\frac{53}{88}$ = ·6.

The distance between the axes of the columns is 10 modules 16 parts, the height of the semi-arch is 3½ modules 3 parts, and between the crown of it and the under side of the architrave is 2 modules; the whole height, including the entablature, being 22 modules 15½ parts.

2625. *Fig.* 902. represents the Corinthian arcade without pedestal. The measurement, as before, is from centre to centre of pier.

The whole area, 25·2 x 11·33, in round numbers			= 288·5
Area of semi-arch, $\frac{7\cdot76\times7\cdot76\times\cdot7854}{2}$ =	23·6		
Rectangle under it, 14·11 x 7·76 =	109·5		
	Total voids, therefore,	=	133·1
			155·4
Entablature, 10·36 x 5·6			58·0
Leaves for the supporting parts			97·4

In the Corinthian example, therefore, the supporting parts are 97, those supported 58, and the voids 133. The ratio between the solid and void parts = ·8, and the ratio of the supports to the weights $\frac{58}{97}$ = ·59. The distance between the axes of the columns is 11 modules and 6 parts, the height of the semi-arch is 3 modules 16 parts, and between the crown of it and the under side of the architrave is 2 modules 3½ parts; the whole height, including the entablature, being 25 modules 3½ parts.

2626. The laws laid down by Chambers for regulating arcades are as follow:—"The void or aperture of arches should never be much more in height nor much less than double their width; the breadth of the pier should seldom exceed two thirds, nor be less than one third of the width of the arch, according to the character of the composition, and the angular piers should be broader than the rest by one half, one third, or one fourth." . . . "The height of the impost should not be more than one seventh, nor need it ever be less than one ninth of the width of the aperture, and the archivolt must not be more than one eighth nor less than one tenth thereof. The breadth of the console or mask, which serves as a key to the arch, should at the bottom be equal to that of the archivolt, and its sides must be drawn from the centre of the arch. The length thereof ought not to be less than one and a half of its bottom breadth, nor more than double."

2627. The ratios that have been deduced by comparing the void and solid parts, if there be any reason in the considerations had, show that this law of making arches in arcades of the height of 2 diameters is not empirical, the following being the results of the use of the ratios in the arcade without, and that with pedestal, of which we shall presently treat. Thus in the

		Diameters.		Diameters
Tuscan arcade without pedestal,	$\frac{13{\cdot}5 \text{ height}}{6{\cdot}5 \text{ width}}$	$=2{\cdot}0$; with pedestals,		$\frac{17{\cdot}5}{9{\cdot}5}=1{\cdot}84$
Doric arcade without pedestal,	$\frac{14{\cdot}0}{7}$	$=2{\cdot}0$	—	$\frac{20{\cdot}0}{10{\cdot}0}=2{\cdot}00$
Ionic arcade without pedestal,	$\frac{15{\cdot}83}{7{\cdot}10}$	$=2{\cdot}2$	—	$\frac{22{\cdot}0}{11{\cdot}0}=2{\cdot}00$
Corinthian arcade without pedestal,	$\frac{18{\cdot}00}{7{\cdot}76}$	$=2{\cdot}3$	—	$\frac{25{\cdot}0}{12{\cdot}0}=2{\cdot}08$

2628. In the examples of the arcades with pedestals, we shall again repeat the process by which the results are obtained, first merely stating them in round numbers. *Fig.* 903 is a

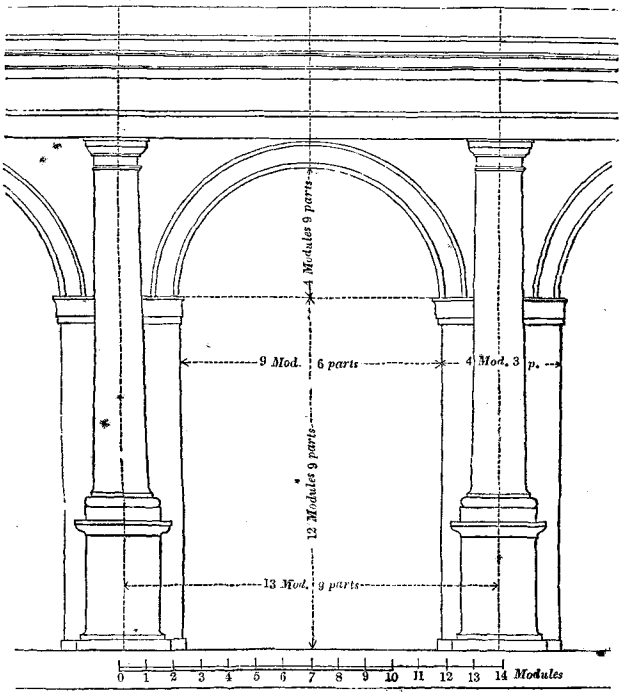

Fig. 903

Tuscan arcade from Vignola's example, as will be the following ones. In this the whole area is 306, omitting fractions, the area of the void is 156, that of the entablature 50, and the supports 100. The ratio of the supported part (the entablature), therefore, is $\frac{50}{100}=\cdot5$, and the supports and weights are very nearly equal to the void. The height of the pedestal is almost 3 modules and 8 parts, the opening 9 modules 6 parts, and the width of the whole pier 4 modules and 3 parts.

The detail of the above result is as follows. —

The whole area, $22{\cdot}30 \times 13{\cdot}75$		$=306{\cdot}62$
Area of semi-arch, $\frac{9{\cdot}5\times9{\cdot}5\times{\cdot}7854}{2}$	$=35{\cdot}43$	
Below that, $12{\cdot}75 \times 9{\cdot}75$	$=121{\cdot}12$	
Total voids, therefore,		$=156{\cdot}55$
		$150{\cdot}07$
Entablature, $13{\cdot}75 \times 3{\cdot}66$		$=50{\cdot}32$
Leaves for supporting parts		$99{\cdot}75$

It will be seen that we have taken the numbers in the preceding paragraph without supplying strictly the decimal parts that arise from the multiplication and subtraction of the several portions compared. The coincidence of the hypothesis with the apparent law is no less remarkable in this example than it will be found in those that follow; and, sceptical as we at first were on the appearances which pointed to it, we cannot, after the examination here and hereafter given, do otherwise than express our conviction that, in carrying out the principles, no unpleasant combination can result.

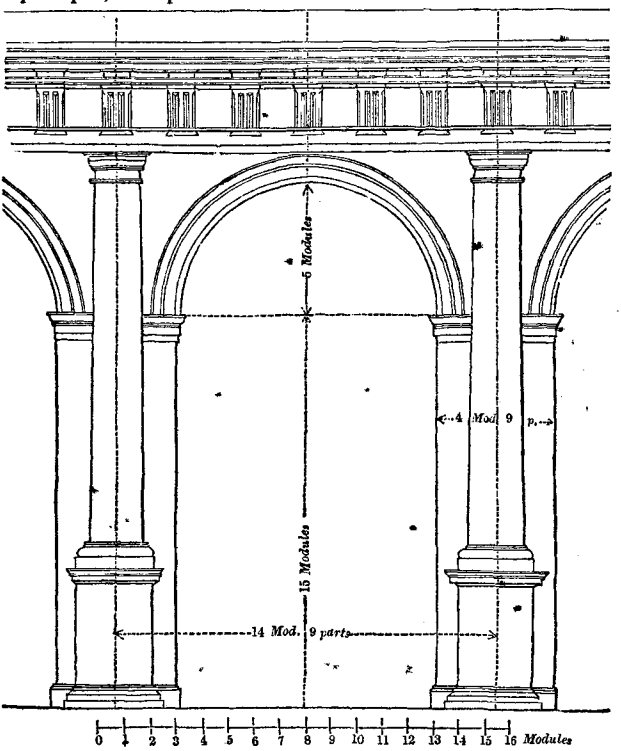

Fig. 904.

2629. *Fig.* 904. exhibits the Doric arcade, whose whole area from centre to centre of columns is 374. The area of the void is 189, that of the entablature 62, and of the supporting parts 112. The ratio of the entablature to the supports is therefore $\frac{62}{112} = .55$, and that of the supports and weights to the voids .9. The height of the pedestal is almost 5 modules and 4 parts, the opening 10 modules, and the width of a pier 4 modules and 9 parts.

As in the preceding example, we think it will be useful to detail the process by which the general results stated have been arrived at. It is curious and interesting to observe the similarity between the cases. It is scarcely possible to believe that accident could have produced it. May not the freemasons of the middle ages have had some laws of this nature which guided their operations? But we will now proceed to the calculation.

The whole area, $25{\cdot}4 \times 14{\cdot}75$		$=374{\cdot}65$
Area of semi-arch, $\frac{10{\cdot}0 \times 10{\cdot}0 \times {\cdot}7854}{2}$	$= 39{\cdot}27$	
Below that, $12{\cdot}75 \times 9{\cdot}75$	$=150{\cdot}00$	
Total voids, therefore,		$=189{\cdot}27$
		$185{\cdot}38$
Entablature, $14{\cdot}75 \times 4{\cdot}25$		$= 62{\cdot}68$
Leaves for supporting parts		$122{\cdot}70$

Herein, as before, the general result in the preceding paragraph has been given in round

numbers, that the mind of the reader may not be distracted from the general proportions. The detail again corroborates the hypothesis, as in the preceding subsection was predicated, and the further we proceed, as will be presently seen, its truth becomes more manifest.

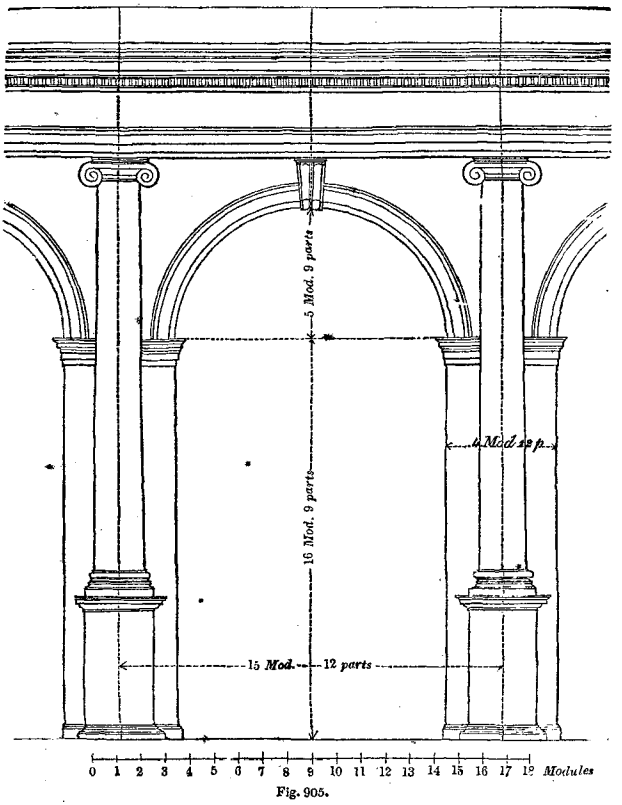

Fig. 905.

2630. The Ionic arcade with a pedestal is shown in *fig.* 905. The whole area is 448 between the axes of the columns; that of the void, 228. The entablature's area is 73, and the supporting parts 146. The ratio, therefore, of the load to the support is $\frac{73}{146} = \cdot 5$, and supports and weights are very nearly equal to the void. The height of the pedestal is 6 modules, the opening 11 modules, and the width of a pier 4 modules and 12 parts.

Once more returning to the detail on which the above proportions are based, and which in this as in the following example we think it better to supply, observing, as before, that the numbers above stated are given roundly, we shall have in the Ionic arcade,

Whole area, $28{\cdot}66 \times 15{\cdot}66$ - - - - - -		$=448{\cdot}81$
Area of semi-arch, $\frac{11 \times 11 \times {\cdot}7854}{2}$	$= 47{\cdot}01$	
Below it, $16{\cdot}5 \times 11$ -	$=181{\cdot}50$	
Total area of voids, therefore, *		$=228{\cdot}51$
		$220{\cdot}30$
Entablature, $15{\cdot}66 \times 4{\cdot}7$ - - - - - -		$= 73{\cdot}50$
Leaves for supporting parts - - - - - -		$146{\cdot}80$

Whence it will be seen that the round numbers first given are shown to be sufficiently accurate for exemplification of the law, and that the further we examine the hypothesis the more closely we find it connected with the theory of weights and loads that has occupied a very considerable portion of this Book, and which we hope may not have had the effect of exhausting the reader's patience. We trust we shall have his pardon for pursuing the course we have taken.

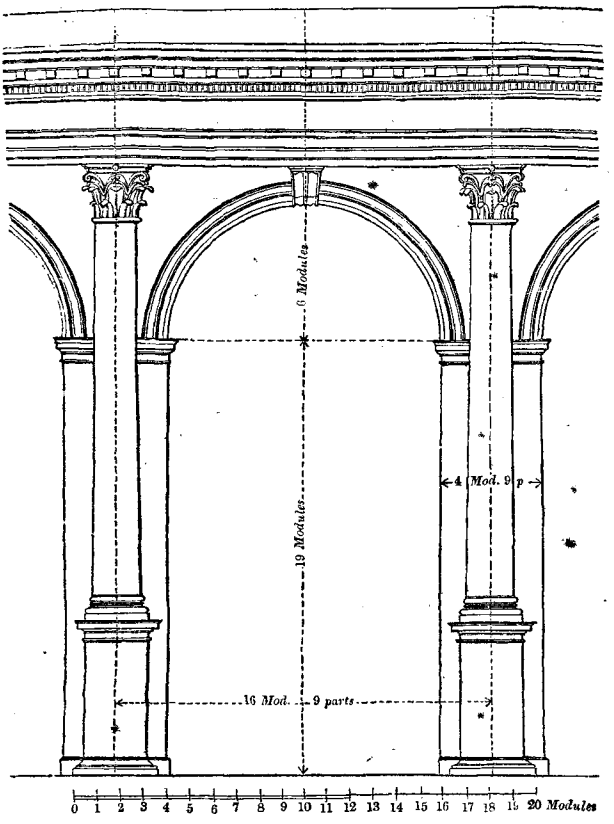

Fig. 906.

2631. *Fig.* 906. is an arcade with pedestals of the Corinthian order. Its total area is 528, that of the void 284, the area of the entablature 84, and that of the supporting parts 159. Hence, the ratio of the load to the support is $\frac{84}{159} = \cdot 52$, and the supports and weight are equal in area to the void within a very small fraction. The height of the pedestal is $6\frac{1}{2}$ modules, the opening is 12 modules wide, and the width of a pier is 4 modules and 9 parts.

We here close the curious proofs of a law whose existence, we believe, has never been suspected by modern architects. It was clearly unknown to Rondelet, and but for the work of Lebrun already quoted, we might never have been led to the investigation of it. That author himself, as we believe, did not entertain any notion of it.

In the Corinthian arcade with pedestal we have

Whole area, $32 \times 16 \cdot 5$		$= 528 \cdot 00$
Area of semi-arch, $\frac{12 \times 12 \times \cdot 7854}{2}$	$= 56 \cdot 05$	
Below it, 19×12	$= 228 \cdot 00$	
Total area of voids, therefore,		$= 284 \cdot 05$
		$243 \cdot 95$
Entablature, $16 \cdot 5 \times 5 \cdot 09$		$= 84 \cdot 10$
Leaves for supporting parts		$159 \cdot 85$

Thus, again, the law seems to be borne out, and to prove that the assumptions we have been making are not those of empiricism.

2632. In *fig.* 907. are collected the imposts and archivolts used in the arcades of the different orders.

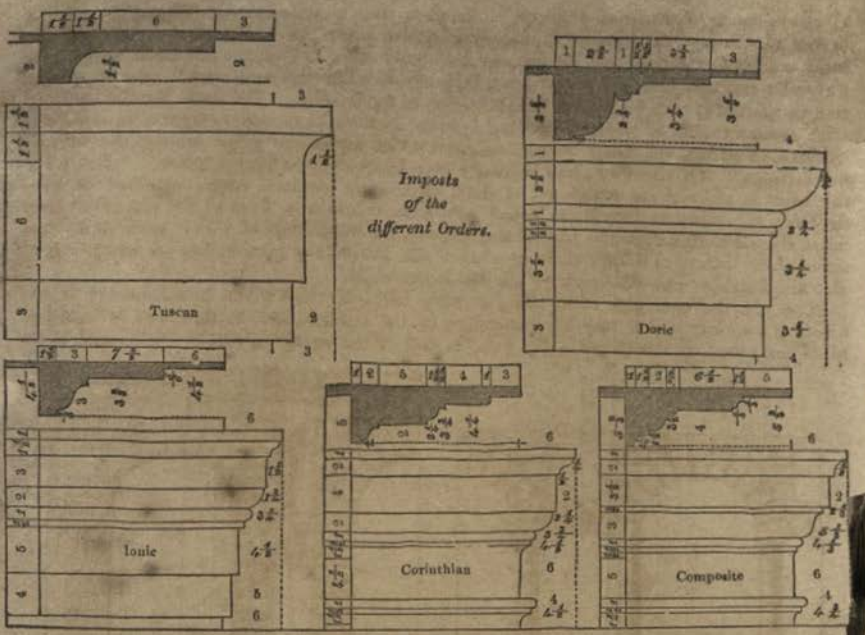

Fig. 907.

2633. We are not of the opinion of Sir William Chambers in respect of the arcades which Vignola has given; that author had not, we think, critically examined their composition, and we confess we do not think his own examples are improvements on those of the master in question; but we are willing to admit that in the examples of arcades with pedestals, they would have been much improved by assigning a greater height generally to the plinths of the pedestals, which are, doubtless, much too low, and might be well augmented by adding to them a portion of the dies of the pedestals.

2634. Great as is our admiration of Palladio, we do not think it necessary to say more relative to his arcades, than that he has given only designs of arches with pedestals, and that their height is from one and two thirds to two and a half of their width. His piers are generally 3¾ modules, except in the Composite order, wherein they are 4½ modules.

2635. Scamozzi makes his Tuscan arch a little less than double its width, increasing the height gradually to the Corinthian arch with pedestals to nearly twice and a half the width. He diminishes his piers as the delicacy of the order increases, his Corinthian piers being only 3¾ modules in width. We do not, however, think it necessary to dwell longer on this part of the subject, and shall close it by observing that the impost of the arch should not much vary from half a module in height, and that the width of the archivolt, which should touch the shaft of the column or pilaster in the geometrical elevation, at its springing, is necessarily prescribed by the width of pier left after setting out the column upon it. Where columns are used on piers, their projection must be such that the most prominent member of the impost should be in a line with the axis of the column on the transverse section. In Ionic, Composite, and Corinthian arcades, however, it may project a little beyond the axis of the columns, to avoid the disagreeable mutilations which are otherwise rendered necessary in the capitals. Arcades should project not less than their width from the front of the wall which backs them." With regard to their interior decoration," says Chambers, " the portico may either have a flat ceiling or be arched in various manners. Where the ceiling is flat, there may be on the backs of the piers, pilasters of the same kind and dimensions with the columns on their fronts; facing which pilasters there must be others like them on the back wall of the portico. Their projection as well as that of those against the back of the piers may be from one sixth to one quarter of their diameter. These pilasters may support a continued entablature, or one interrupted and running across the portico over every two pilasters to form coffers; or the architrave and frieze only may be continued, while the cornice alone is carried across the portico over the pilasters as before, and serves to form compartments in the ceiling, as is done in the vestibule of the Massini palace at Rome, and in the great stable of the King's mews, near Charing Cross," — no longer in existence, having been destroyed to make way on its site for the execrable mass of absurdity to which the government who sanctioned it have facetiously

given the name of National Gallery. Chambers thus continues: — "Where the portico is arched, either with a semi-circular or elliptical vault, the backs of the piers and the inner wall of the portico may be decorated with pilasters, as is above described, supporting a regular continued entablature, from a little above which the arch should take its spring, that no part of it may be hid by the projection of the cornice. The vault may be enriched with compartments of various regular figures, such as hexagons, octagons, squares, and the like, of which, and their decorations, several examples are given among the designs for ceilings." Of these we shall hereafter give figures in the proper place. "But when the vault is groined, or composed of flats, circular or domical coves, sustained on pendentives, the pilasters may be as broad as are the columns in front of the piers, but they must rise no higher than the top of the impost, the mouldings of which must finish and serve them instead of a capital, from whence the groins and pendentives are to spring, as also the bands or *arcs-doubleaux* which divide the vault."

2636. In the examples of arcades, we have followed those given by Chambers, as exhibiting a variety which may be instructive to the student, and at the same time afford hints for other combinations. *Fig.* 908. is one of the compositions of Serlio, and is an

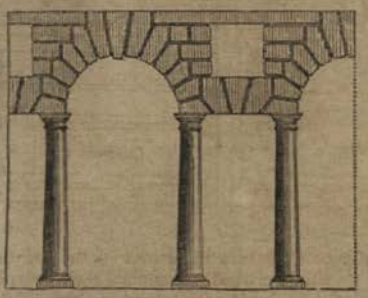

Fig. 908.

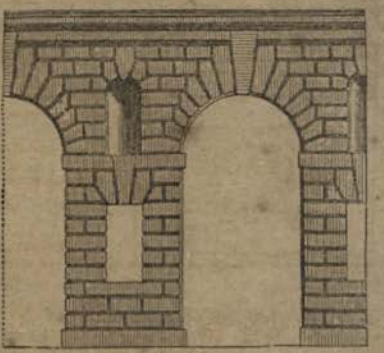

Fig. 909.

xpedient for arching in cases where columns have been provided, as in places where the se of old ones may be imposed on the architect. The larger aperture may be from ½ to 5 diameters of the column in width, and in height double that dimension. The maller opening is not to exceed two thirds of the larger one, its height being determined y that of the columns. Chambers thinks, and we agree with him, that this sort of disposition might be considerably improved by adding an architrave cornice or an entablature o the column, by omitting the rustics and by surrounding the arches with archivolts. It s not to be inferred, because this example is given, that it is inserted as one to be followed except under very peculiar circumstances. Where an arrangement of this kind is adopted, are must be used to secure the angles by artificial means.

2637. *Fig.* 909. is given from the cortile of the castle at Caprarola by Vignola, a structure which in the First Book of this work we have (346.) already mentioned. The height of he arches is somewhat more than twice their width. From the under side of the arch to he top of the cornice is one third of the height of the arch, the breadth of whose pier is qual to that of the arch, and the aperture in the pier about one third of its breadth.

2638. A composition of Bramante, executed in the garden of the Belvedere at Rome, is iven at *fig.* 910. The arch in height is somewhat more than twice its width, and the

Fig. 910.

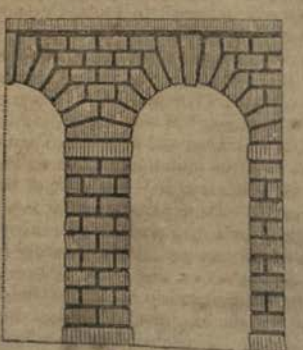

Fig. 911.

breadth of the pier equal to the opening. By dividing the latter into twelve parts we have a measure which seems to have prevailed in the mind of the architect, inasmuch as two of them will measure the parts of the pier supporting the archivolts, four the space for the two columns, two for the intervals between the niche and the columns, and four for the niche. Half the diameter of the arch measures the height of the pedestal; the columns are of the height of ten diameters, and their entablature one quarter of the height of the columns. The impost and archivolt are each equal to half a diameter of the column.

2639. *Fig.* 911. is an example whose employment is not uncommon in the designs of Palladio, and was considered by our great countryman Inigo Jones to be worthy of his imitation. The arch may be taken at about twice its width, and the pier not less than one nor more than two thirds of the width of the aperture.

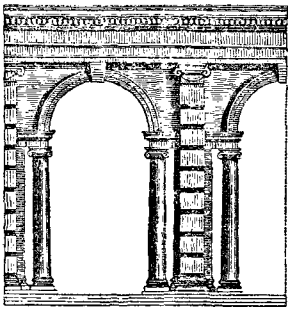

Fig. 912.

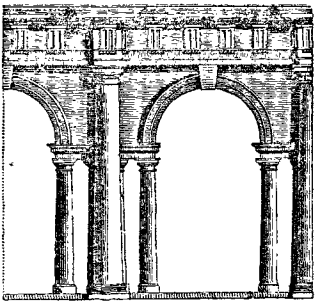

Fig. 913.

2640. The example in *fig.* 912. is from the hand of Vignola, and was executed for one of the Borghese family at Mondragone, near Frascati. In it the arch is a little more in height than twice its width, and the breadth of the pier columns supporting the arch includes a little less than the width of the arch itself. We are not quite satisfied in having here produced it as an example, though, compared with the following one, we scarcely know whether we should not on some accounts prefer it.

2641. The last example (*fig.* 913.) is one by that great master, Palladio, from the basilic at Vicenza. From the figure it is impossible to judge of its beauty in execution, neither can any imitation of it, unless under circumstances in every respect similar, produce the sensation with which the building itself acts on the spectator; yet in the figure it appears meagre and nothing worth. We can therefore easily account for the conduct of the critics, as they are called, who, never having seen this master's works, indulge in ignorant speculations of the pictorial effects which his compositions produce. Though not entirely agreeing with Chambers in his concluding observations on arcades and arches, we may safely transfer them to these pages. "The most beautiful proportion," he observes, "for compositions of this kind is, that the aperture of the arch be in height twice its width; that the breadth of the pier do not exceed that of the arch, nor be much less; that the small order be in height two thirds of the large columns, which height being divided into nine parts, eight of them must be for the height of the column, and the ninth for the height of the architrave cornice, two fifths of which should be for the architrave and three for the cornice. The breadth of the archivolt should be equal to the superior diameter of the small columns, and the keystone at its bottom must never exceed the same breadth."

Sect. XI.

Orders above Orders.

2642. Vitruvius, in the fifth chapter of his book "On the Forum and Basilica," in both which species of buildings it is well known that orders above orders were employed, instructs his readers: — "The upper columns are to be made one fourth less than those below" (*quarta parte minores quam inferiores sunt constituendæ*), "and that because the lower being loaded with a weight, ought to be the stronger; because, also, we should follow the practice of nature, which in straight-growing trees, like the fir, cypress, and pine, makes the thickness at the root greater than it is at top, and preserves a gradual diminution throughout their height. Thus, following the example of nature, it is rightly ordered that bodies which are uppermost should be less than those below, both in respect of thickness." It is curious that the law thus given produces an exactly similar

laid down by Scamozzi, p. 2. lib. v. cap. ii., whereon we shall have more presently to speak. Galliani, Chambers, and others have considered the above-quoted passage of Vitruvius in connection with another in chap. vii. of the same book, which treats of the portico and other parts of the theatre, wherein the author states, after giving several to this question unimportant details, "The columns on this pedestal" (that of the upper order) "are one fourth less *in height*" (quartâ parte minores *altitudine* sint) "than the lower columns." The reader will here observe the word *altitudine* is introduced, which does not appear in the passage first quoted; and we beg him, moreover, to recollect that the last quotation relates entirely to the scene of the ancient theatre, in which liberties were then taken with strict architectural proportion as much as they are in these later days. Those who think that because Vitruvius interlarded his work with a few fables, he is therefore an author not worth consulting, as ephemeral critics have done in respect of that great master of the art, Palladio, may opine we have wasted time in this discussion; but, adopting the old maxim of Horace, "Non ego paucis offendar maculis," we shall leave them to the exposure which, with the instructed architect, their own ignorance will ultimately inflict on them, and to the enjoyment of the felicity attendant on a slight knowledge of the subject a person is in the habit of handling.

2643. We will now place before the student our own reading and explanation of the passage of Vitruvius relative to the use of orders above orders, and attempt to show what we conceive to be its real meaning. In *fig.* 914. the diagram exhibits an Ionic placed above a Doric column: the entablature (which however does not belong to the consideration) being in both cases one fourth of the height of the column. Inasmuch as in our previous rules (following Vignola) it will be recollected that the module of the Doric order is subdivided into twelve, whilst that of the Ionic is subdivided into eighteen parts, we must, for the purpose of obtaining an uniformity of measures in both orders, reduce those of either to the other to obtain similar dimensions. Instead, therefore, of measuring the upper order by itself, which would not afford the comparison sought, we shall have to reduce its established measures to those of the lower one, or Doric, and this, as well as the measurement of the lower order itself, is taken in modules and decimal parts of its semidiameter. Thus, the lower order being 2 modules at its bottom diameter and 1·666 modules at its upper diameter, the mean, without descending to extreme mathematical nicety, may be taken at 1·833, which multiplied by the height, 18 modules = 32·994, the area of a section through the centre of the column. Now if the upper columns are to be the same thickness at the bottom as the lower ones are at the top, that is, 1·666 module of the lower order, their upper diameters will be 1·387 (that is, five sixths of the lower diameter), and the mean will be 1·526, which, multiplied by 16, the height, = 24·416 the area of a section down the centre of the column, and just one fourth less than that of the lower column. The investigation tends to show us that we should not lightly treat the laws laid down by Vitruvius and his followers at the revival of the arts, for we may be assured that in most cases they are not empirical, but founded on proper principles. We cannot, however, leave this point without giving another reason, which is conclusive against Chambers's construction of the passage; it is, that supposing the upper column's lower diameter to be the same or nearly so as the lower column's upper diameter, if the *fourth* part had relation to the height instead of the bulk, we should have had the absurdity in the illustration above given, of an *Ionic* column in the second order only six and three quarters diameters high, whilst the lower or Doric is nine diameters in height.

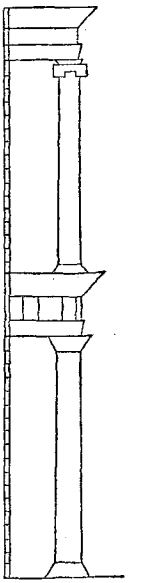

Fig. 914.

2644. Scamozzi, we doubt not, thought as we have expressed ourselves on this subject, and we here translate the words he uses in the eleventh chapter of his sixth book (second part). "Hence it is more satisfactory, and they succeed better and are more pleasing to the eye, when these columns (the upper ones) are made according to their proper diminution, so that the lower part of the upper column may be just the thickness of the upper part of the lower one, and so from one to the other, as may be seen in the Ionic order of the Theatre of Marcellus and other edifices; and this is the reason and natural cause that it is the same as though out of a long and single tree the shafts were cut out one after the other."

2645. The laws of solidity seem to require that where more than one order is used, the strongest is to occupy the lower situation; thus the Doric is placed on the Tuscan, the Ionic on the Doric, the Corinthian on the Ionic, and the Composite on the Corinthian; though, with respect to the last, we find examples of importance wherein the reverse has been the case. Two tiers of columns should not be of the same order, neither should an intermediate order be omitted; such, for instance, as placing the Ionic on the Tuscan column, or the Corinthian on the Doric; for by this practice many irregularities are introduced, especially in the details of the members.

2646. Frontwise the axes of the upper and lower columns must be in the same vertical plane, but viewed in flank this is not absolutely necessary; they should not, however, deviate too much from it. In the theatre of Marcellus the axes of the upper columns are nearly a foot within those of the Doric below them; but circumstances required this, and there is no great objection to the practice if the solidity of the structure be not lessened by it. Chambers observes that the retraction should never be greater than at the theatre of Marcellus, where the front of the plinth in the second order is in a line with the top of the shaft in the first. When the columns are detached, they should be placed centrally over each other, so that the axes of the upper and under ones may form one continued line, by which means solidity is gained as well as a satisfactory result to the eye. As to the false bearings of the bases of the upper order on the profile, this is a matter neither really affecting stability nor the appearance of the design.

2647. In England there are not many examples of orders above orders, while on the Continent the practice has not been uncommon; but it is always a matter of great difficulty so to arrange them as to avoid irregularities where triglyphs and modillions in the same design meet in the composition. We have used the figures of Chambers for our illustration here, because they are nearly coincident with the rules of Vitruvius and Scamozzi, and we shall now place them before the reader, observing that the irregularities alluded to are almost altogether avoided.

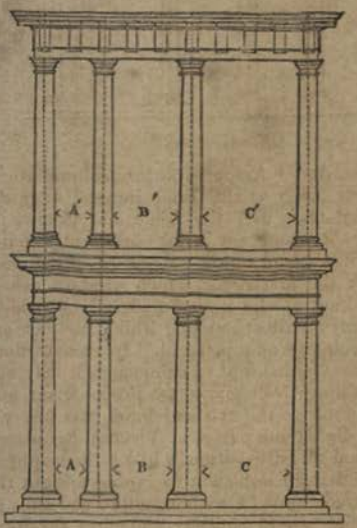

Fig. 915.

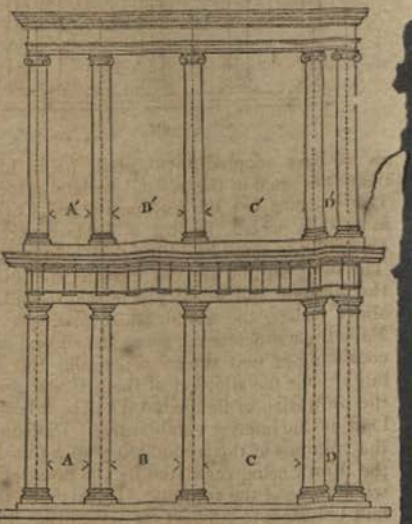

Fig. 916.

2648. *Fig.* 915. exhibits the Doric over the Tuscan order. The intervals A, B, and C are respectively $2\frac{1}{2}$, $4\frac{1}{2}$, and $6\frac{1}{2}$ modules; and A′, B′, and C′, 3, $5\frac{1}{2}$, and 8 modules of their order. The entablature of the lower order is $3\frac{1}{4}$ modules, the column, including base and capital, being 14 modules high; and the entablature of the upper order is 4 modules high, the column with its base and capital being 16 modules in height.

2649. The distribution of the Doric and Ionic orders is given in *fig.* 916., wherein the intervals A, B, and C are respectively 3, $5\frac{1}{2}$, and 8 modules; D, ·7 module; and A′, B′, C′, and D′ respectively 4, 7, 10, and $1\frac{1}{4}$ modules. The Doric order in this example is 20 modules high, whereof 4 are assigned to the entablature; the Ionic 22 modules high, whereof 4 belong to the entablature.

2650. In *fig.* 917. is represented the Corinthian above the Ionic order; the intervals A, B, C, D are respectively 5, 6, 7, and 1 modules, and those of A′, B′, C′ D′ respectively 6·4, 7·6, 8·8, 1·6 modules; the lower order is $22\frac{1}{2}$ modules high, 18 being given to the column with its base and capital; and the upper or Corinthian order is $24\frac{1}{2}$ modules high, whereof 20 belong to the height of the column, including its base and capital.

2651. The last (*fig.* 918.) is of the Corinthian order above and Composite below. In the lower order the intervals A, B, C, D are $4\frac{3}{4}$, 6, 7, and 1 modules respectively, and A′, B′, C′, and D′, in the upper order, 6, 7·6, 8·8, and 1·6 modules respectively The whole height of the Corinthian order is 25 modules, whereof 5 are given to the entablature; the Composite order here is $24\frac{1}{2}$ modules, of which 20 belong to the column, including the base and capital.

2652. We insert the observations of Chambers relative to the above four figures, which,

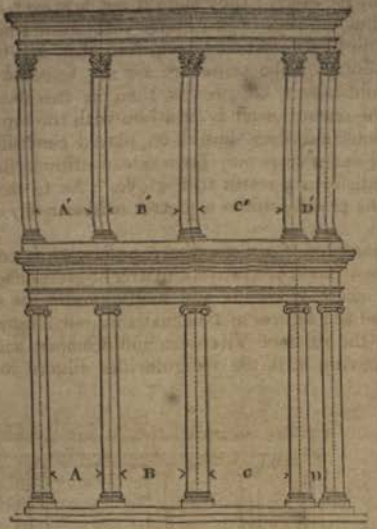

Fig. 917.

Fig. 918.

as we have adopted them, shall be in his own words. "Among the intercolumniations there are some in the second orders extremely wide, such as the Ionic interval over the Doric aræostyle; the Composite and Corinthian intervals over the Ionic and Composite aræostyle, which, having a weak meagre appearance, and not being sufficiently solid, excepting in small buildings, are seldom to be suffered, and should seldom be introduced. The most eligible are the eustyle and diastyle for the first order, which produce nearly the diastyle and aræostyle in the second." Speaking of the use of pedestals in orders above orders, the author thus proceeds: — "Many architects, among which number are Palladio and Scamozzi, place the second order of columns on a pedestal. In compositions consisting of two stories of arcades this cannot be avoided, but in colonnades it may and ought; for the addition of the pedestal renders the upper ordonnance too predominant, and the projection of the pedestal's base is both disagreeable to the eye and much too heavy a load on the inferior entablature. Palladio, in the Barbarano palace at Vicenza, has placed the columns of the second story on a plinth only, and this disposition is best; the height of the plinth being regulated by the point of view, and made sufficient to expose to sight the whole base of the column. In this case the balustrade must be without either pedestals or half balusters to support its extremities, because these would contract and alter the form of the column; its rail or cap must be fixed to the shafts of the columns, and its base made level with their bases; the upper torus and fillet of the columns being continued in the interval, and serving as mouldings to the base of the balustrade. The rail and balusters must not be clumsy; wherefore it is best to use double-bellied balusters, as Palladio has done in most of his buildings, and to give the rail a very little projection, that so it may not advance too far upon the surface of the column, and seem to cut into it. In large buildings the centre of the baluster may be in a line with the axis of the column; but in small ones it must be within it, for the reason just mentioned. The height of the balustrade is regulated in a great measure by its use, and cannot well be lower than three feet, nor should it be higher than three and a half or four feet. Nevertheless, it must necessarily bear some proportion to the rest of the architecture, and have nearly the same relation to the lower order, or whatever it immediately stands upon, as when a balustrade is placed thereon chiefly for ornament. Wherefore, if the parts are large, the height of the balustrade must be augmented, and if they are small it must be diminished; as is done in the Casino at Wilton, where it is only two feet four inches high, which was the largest dimension that could be given to it in so small a building. But that it might, notwithstanding its lowness, answer the intended purpose, the pavement of the portico is six inches lower than the bases of the columns, and on a level with the bottom of the plat-band that finishes the basement."

We must here leave this subject, recommending the student to an intimate acquaintance with the various examples that have been executed, and further advising him to test each of the examples that may fall under his notice by the principles first adverted to in this section, as the only true means of arriving at a satisfactory result.

Sect. XII.

ARCADES ABOVE ARCADES.

2653. As the disposition of one arcade upon another is, under certain regulations, subject to the same laws of voids and solids as the simple arcade of one story, which has formed the subject of a previous section, we shall no further enter into the rules of its combination than to offer a few general observations on the matter in question; and herein, even with the reproach of a want of originality, we shall draw largely on our much-quoted author, Chambers, whose language and figures we are about to use. So sound, indeed, is the doctrine of Chambers in this respect, and so well founded on what has been done by those whom we consider the greatest masters, that we should not be satisfied without transferring his dicta to these pages, and that without any alteration.

2654. "The best," says Chambers, "and, indeed, the only good disposition for two stories of arcades, is to raise the inferior order on a plinth, and the superior one on a pedestal, as Sangallo has done at the Pallazzo Farnese; making both the ordonnances of an equal height, as Palladio has done at the Basilica of Vicenza."

2655. "Scamozzi, in the thirteenth chapter of his sixth book, says that the arches in the second story should not only be lower, but should also be narrower, than those in the first; supporting his doctrine by several specious arguments, and by the practice, as he says, of the ancient architects in various buildings mentioned by him. In most of these, however, the superior arches are so far from being narrower, that they are either equal to or wider than the inferior ones. In fact, his doctrine in this particular is very erroneous, entirely contrary to reason, and productive of several bad consequences; for if the upper arches be narrower than the lower ones, the piers must of course be broader, which is opposite to all rules of solidity whatever, and exceedingly unsightly. The extraordinary breadth of the pier on each side of the columns in the superior order is likewise a great deformity; even when the arches are of equal widths it is much too considerable. Palladio has, in the *Carità* at Venice, and at the Palazzo Thiene in Vicenza, made his upper arches wider than the lower ones, and I have not hesitated to follow his example; as by that means the weight of the solid in the superior order is somewhat diminished, the fronts of the upper piers bear a good proportion to their respective columns, and likewise to the rest of the composition."

2656. "In a second story of arcades there is no avoiding pedestals. Palladio has, indeed, omitted them at the Carità, but his arches there are very ill proportioned. The extraordinary bulk and projection of these pedestals are, as before observed, a considerable defect; to remedy which in some measure they have been frequently employed without bases, as in the theatre of Marcellus, on the outside of the Palazzo Thiene, and that of the Chiericato in Vicenza. This, however, helps the matter but little; and it will be best to make them always with bases of a moderate projection, observing at the same time to reduce the projection of the bases of the columns to ten minutes only, that the die may be no larger than is absolutely necessary; and in this case particular care must be taken not to break the entablature over each column of the inferior order, because the false bearing of the pedestal in the second order will by so doing be rendered far more striking, and in reality more defective, having then no other support than the projecting mouldings of the inferior cornice. There is no occasion to raise the pedestals of the second order on a plinth, for as they come very forward on the cornice of the first order, and as the point of view must necessarily be distant, a very small part only of their bases will be hid from the eye."

2657. "The balustrade must be level with the pedestals supporting the columns; its rail or cornice and base must be of equal dimensions, and of the same profile with theirs. It should be contained in the arch and set as far back as possible, that the form of the arch may appear distinct and uninterrupted from top to bottom; for which reason, likewise, the cornice of the pedestals must not return nor profile round the piers, which are to be contained in straight perpendicular lines from the imposts to the bases of the pedestals. The back of the rail may either be made plain or sunk into a panel in form of an open surbase, for so it will be most convenient to lean upon, and it should be in a line with or somewhat recessed within the backs of the piers. The back part of the balustrade may be adorned with the same mouldings as the bases of the piers, provided they have not much projection; but if that should be considerable, it will be best to use only a plinth crowned with the two upper mouldings, that so the approach may remain the more free."

2658. In *fig.* 919. is a Doric above a Tuscan arcade, from the example given by Chambers, whereon, before giving the dimensions of the different parts, we shall merely observe of it that the voids or arcades themselves are in round numbers to the solids as 295 to 205, being vastly greater. We are inclined to think that the voids in this case are rather too great in volume, and that, had they been reduced to one half their height exactly, the

proportions would have been somewhat more pleasing. It is true that a trifling irregularity would have been introduced into the triglyphs of the upper order, or rather the metopæ between them; but that might have been easily provided against by a very trifling alteration in the height of the frieze itself. This fault of making the voids too large pervades Chambers's examples, and but that we might have been thought too presuming we should have slightly altered the proportions, little being requisite to bring them under the laws which we have thought to be founded on reason and analogy. We have indeed throughout this work refrained from giving other than approved examples, preferring to confine ourselves to observations on them when we have not considered them faultless.

Fig. 919.

2659. In the figure the clear width of the lower arcade is 7½, and its height 14½ modules. The width of each pier is 1 module. Of the upper arcade the width is 9½, and the height 18·233 modules. The width of the piers is 1½ module each. The height of the plinth of the lower order is 1½ module, that of the column, including base and capital, 14½ modules, the entablature 3½. The height of the pedestal of the upper order is 3·733 modules, of the column with its base and capital 16, and of the entablature 3·733 modules. In the proportions between the voids and solids above taken the balustrade is not considered as a solid, because, in fact, it is nothing more than a railing for the protection of those using the upper story. As we have expressed our desire to give the examples of others rather than our own, we feel bound to recommend the student to set up the diagram in question, with the simple alteration of reducing the solids nearly to an equality with the voids, which may be done with sufficient accuracy by assigning to the lower arcade a module less in width than Chambers has done; and we venture to say that he will be surprised at the difference, as regards grace and elegance, which will result from the experiment. It is to be understood that no change is proposed in the other dimensions of the ordonnance, the width of piers, orders, entablatures, all remaining untouched.

2660. In *fig.* 920. we give another example from Chambers, which, in our opinion, requires a rectification to bring it into proper form. Herein the Ionic is used above the Doric arcade, and the voids to the solids are as 3·33 to 2·98, being much more than equal to them. In this, as in the former example, we should have preferred a greater equality between the solids and voids, though in that under consideration there is a nearer approximation to it.

2661. In the figure the clear width of the lower arch is 8½, and its height 16½ modules; the width of each pier is 1 module. Of the upper arcade the width is 10½, and the height 20½ modules. The width of the piers is 1½ module each. The height of the plinth of the lower order is 1½ module that of the column, including the base and capital, 16½ modules, and of the entablature 4 modules. The height of the pedestal of the upper order 4 modules, of the column, including base and capital, 18 modules, and of the entablature 4, and of the balustrade above it 3½.

2662. The dimensions of the Ionic and Corinthian arcades in *fig.* 921. are as follow: — Clear width of lower arch 9 modules, its height 18½ modules. The width of each pier is 1 module. Of the upper arcade the width of an arch 15⅔ modules, and its height 23 modules. The width of

Fig. 920.

Fig. 921.

the piers is 1¼ module each. The height of the plinth to the lower order is 1⅞ module; of the column, including base and capital, 18 modules; the entablature 4½ modules. The pedestal of the upper order is 4½ modules high; column, including base and capital, 20 modules; entablature 4½ modules; and, lastly, the balustrade is 3¾ modules in height.

Fig. 922.

2663. *Fig.* 922. is an arrangement adopted by Palladio in his basilica at Vicenza, being the dimensions, or nearly, of the arcades on the flanks. The intermediate ones are much wider. In the basilica, however, the entablature breaks round the columns of the orders. The width between the axes of the columns of the lower order is 15 of their modules. The arch is 15 modules high and 7⅞ wide. The order wherefrom the arch springs is 10⅝ modules high; from axis to axis of the small columns in the lower arcade is 9 modules. The height of the plinth is 1½ module, of the principal columns, including bases and plinths, 16½ modules, and of their entablature 4 modules. In the upper arcade the distance between the axes of the principal columns is 18 of their modules. Their pedestals are 4 modules high, the columns, including bases and capitals, 18 modules, and entablature 4 modules high. The width of the arch is 9½ modules, and its height 20⅝ modules. The height of the small columns is 11·733 modules high, including their entablature.

2664. The use of arcades above arcades seems from its nature almost confined to public buildings, as among the ancients to their theatres and amphitheatres. In the interior quadrangles or courts of palaces they have been much employed on the Continent, and in the magnificent design made by Inigo Jones for the palace at Whitehall are to be found some very fine examples.

Sect. XIII.

Basements and Attics.

2665. When the order used for decorating the façade of a building is placed in the middle or second story, it is seated on a story called the *basement*. The proportion of its height to the rest must in a great measure depend on the use to which its apartments are to be appropriated. "In Italy," observes Chambers, "where their summer habitations are very frequently on that floor, the basements are sometimes very high. At the palace of Porti, in Vicenza, the height is equal to that of the order placed thereupon; and at the Thiene, in the same city, its height exceeds two thirds of that of the order, although it be almost of a sufficient elevation to contain two stories; but at the Villa Capra, and at the Loco Arsieri, both near Vicenza, the basement is only half the height of the order; because in both these the ground floor consists of nothing but offices." It may hence be gathered that no absolute law can be laid down in reference to the height of a basement story. Yet we may state, generally, that a basement should not be higher than the order it is to support, for it would in that case detract from the principal part of the composition, and, in fact, would be likely to interfere with it. Besides which, the principal staircase then requires so many steps, that space is wasted for their reception. "Neither," says Chambers, "should a basement be lower than half the height of the order, if it is to contain apartments, and consequently have windows and entrances into it; for whenever that is the case the rooms will be low, the windows and doors very ill formed, or not proportional to the rest of the composition, as is observable at Holkham: but if the only use of the basement be to raise the ground floor, it need not exceed three, four, or at the most five or six feet in height, and be in the form of a continued pedestal."

2666. Basement stories are decorated generally with rustic work of such various kinds, that we fear it would be here impossible to describe or represent their varieties. Many are capriciously rock-worked on their surface, others are plain, that is, with a smooth surface. The height of each course, including the joints, should on no account be less than one module of the order which the basement supports; their length may be from once and a half to thrice their height. As respects the joints, these may be square or chamfered off. When square joints are used, they should not be wider than one eighth part of the

height of the rustic itself, nor narrower than one-tenth, their depth not exceeding their width. When the joints are chamfered, the chamfer should be at an angle of forty-five degrees, and the whole width of the joint from one third to one fourth of the height of the rustic.

2667. The courses are sometimes (often on the Continent) laid without showing vertical joints; but, as Chambers says, this "has in general a bad appearance, and strikes as if the building were composed of boards rather than of stone. Palladio's method seems far preferable, who, in imitation of the ancients, always marked both the vertical and the horizontal joints; and whenever the former of these are regularly and artfully disposed, the rustic work has a very beautiful appearance." We shall presently make a few remarks on the subject of rusties; but here, to continue and finish that more immediately under consideration, have to add, that when a high basement is used, it is not uncommon to crown it with a cornice, as may be seen in *fig.* 909.; but the more common practice is to use a platband only (as in *fig.* 911.), whose height should not be greater than that of a rustic exclusive of the joint. Of a similar height should be made the zoccolo or plinth; but this may, and ought, perhaps, to be somewhat higher. When arches occur in basements, the platband, which serves for the impost, should be as high as a course of rustics, exclusive of the joint; and if the basement be finished with a cornice, such basement should have a regularly moulded base at its foot; the former to be about one thirteenth of the whole height of the basement, and the base about one eighteenth, without the plinth.

2668. The Attic — which is used instead of a second order where limits are prescribed to the height of a building, examples whereof may be seen at Greenwich Hospital, and in the Valmarano palace, by the great Palladio, at Vicenza — should not exceed in height one-third of the order whereon they are placed, neither ought they to be less than one quarter. Bearing some resemblance to a pedestal, the base, die, and cornice whereof they are composed may be proportioned much in the same way as the respective divisions of their prototypes. They are sometimes continued without, and sometimes with, breaks over the column or pilaster of the order which they crown. If they are formed with pilasters, such ought to be of the same width as the upper diameter of the order under them, never more. In projection they should be one quarter of their width at most. They may be decorated with sunk moulded panels if necessary; but this is a practice rather to be avoided, as is most especially that of using capitals to them — a practice much in vogue in France under Louis XV.

2669. We now return to the subject of the rock-worked rustic, whereof, above, some notice was promised. The practice, though occasionally used by the Romans, seems to have had its chief origin in Florence, where, as we have in a former Book (329.) observed, each palace resembled rather a fortification than a private dwelling. Here it was used to excess; and if variety in the practice is the desire of the student, the buildings of that city will furnish him with an almost infinite number of examples. The introduction of it gives a boldness and an expression of solidity to the rustics of a basement which no other means afford. In the other parts of Italy it was sparingly applied, but with more taste. Vignola and Palladio seem to have treated it as an accident productive of great variety rather than as a means of decoration. The last-named architect has in the Palazzo Thiene carried it to the utmost extent whereof it is susceptible. Yet, with this extreme extent of application, the design falls from his hands full of grace and feeling. To imitate it would be a dangerous experiment. De Brosse failed at the Luxembourg, and produced an example of clumsiness which in the Palazzo Pitti does not strike the spectator.

2670. Rustics and rockwork on columns are rarely justifiable except for the purpose of some particular picturesque effect which demands their prominence in the scene, or street view, as in the gateway at Burlington House in Piccadilly,—of which a good view, with the house itself, is to be seen in the "Builder" for 1854, p. 559. It was pulled down about 1867.

SECT. XIV.

PILASTERS.

2671. Pilasters, or square columns, were by the Romans termed *antæ*, by the Greeks *parastatæ*. This last word implies the placing one object standing against another, a sufficiently good definition of the word, inasmuch as in ninety-nine cases out of a hundred they are engaged in or backed against a wall, or, in other words, are portions of square columns projecting from a wall.

2672. It is usual to call a square column, when altogether disengaged from the wall, a *pillar* or *pier*; and we are inclined to think, notwithstanding the alleged type of trees, that the primitive supports of stone buildings were quite as likely to have been square

as round, and that the inconvenience attendant upon square angles may have led the earliest builders to round off the corners, and gradually to bring them to a circular plan. Isolated pillars are rarely found among the examples left us by the ancients; the little temple at Trevi furnishes, indeed, an example, but not of the best period of the art. The principal points to be attended to in their use are their projection, diminution, the mode of uniting the entablature over them with that of their columns, and their flutings and capitals.

2673. In respect of the projection of pilasters, Perrault says they should project one half, and not exceed that by more than a sixth, as in the frontispiece of Nero, unless circumstances require a different projection. The pilasters of the Pantheon project only a tenth part of their width; and sometimes, as in the forum of Nerva, they are only a fourteenth part. But when pilasters are to receive the imposts of arches against their sides, they are made to project a fourth part of their diameter; and this is a convenient proportion, because in the Corinthian order the capital is not so much disfigured. Hence, when pilasters are made to form re-entering angles, they should project more than half their diameter. Many and various opinions have been formed on the propriety of diminishing pilasters. Perrault, with whom we incline to agree, thinks that when one face only projects, pilasters should not be diminished. Those at the flanks of the portico of the Pantheon are without diminution. But when pilasters are on the same line as columns, we want to lay the entablature from one to the other without any projection, in which case the pilaster must be diminished in the same degree as the column itself, speaking of the front face, leaving the sides undiminished, as in the temple of Antoninus and Faustina. When the pilaster has two of its faces projecting from the wall, being on the angle, and one of those faces answers to a column, such face is diminished similarly to the column, as in the portico of Septimius, where the face not corresponding to the column receives no diminution. There are, however, ancient examples where no diminution is practised, as in the interior of the Pantheon, where it is so small as not to be very apparent, being much less than that of the column, as is also the case in the temple of Mars Ultor, and in the arch of Constantine. In these cases, the custom of the ancients is sometimes to place the architrave plumb over the column, which brings it within the line of the pilaster. This may be seen in the temple of Mars Ultor, in the interior of the Pantheon, and in the portico of Septimius. Sometimes this excess is divided into two parts, one whereof goes to the excess of projection of the architrave above the column, and the other half to the deficiency of extent above the pilaster, as in the forum of Nerva. The whole matter is a problem of difficult solution, which Chambers has avoided, but which, with reference to the examples we have cited, will not be attended with difficulty to the student in his practice.

2674. We have above seen that pilasters, when used with columns, are subject to the form and conditions of the latter. As to their flutings we are left more at liberty. In the portico of the Pantheon we find the pilasters fluted and the columns plain. This, however, may have been caused by the difficulty of fluting the latter, which are of granite, whilst the pilasters are of marble. On the other hand, we sometimes find the columns fluted and the pilasters plain, as in the temple of Mars Ultor, and the portico of Septimius Severus. Generally, too, it may be observed that when pilasters project less than half their diameter, their return faces are not fluted. In respect of the number of the flutes, if the examples of the ancients were any guide, there could have been no fixed rule, for in the portico of the Pantheon, the arch of Septimius Severus, and that of Constantine, seven flutes only are cut on the pilasters, whilst the flutes of the pilasters in the interior of the Pantheon are nine in number. This, however, is to be observed, that the flutes must always be of an odd number, except in re-entering pilasters, wherein four are placed instead of three and a half, and five instead of four and a half, when the whole pilaster would have nine. This is done to prevent the ill effect which would be produced in the capital by the bad falling of the leaves over the flutes.

2675. We shall hereafter give from Chambers some representations of pilaster capitals, which, except as regards their width, resemble those of the order they accompany. The practice of the ancients in this respect was very varied. Among the Greeks the form of the pilaster capital was altogether different from that of the column, seeming to have no relationship to it whatever; but on this point the student must consult the works on Grecian antiquities, an example whereof will be found in *fig.* 883.

2676. A pilaster may be supposed to represent a column and to take its place under many circumstances; and, notwithstanding all that was said on the subject by the Abbé Laugier, many years ago, against the employment of pilasters altogether, we are decidedly of opinion that they are often useful and important accessories in a building. It would be difficult to enumerate every situation wherein it is expedient to use pilasters rather than insulated or engaged columns. In internal apartments, where the space is restricted, a column appears heavy and occupies too much room. The materials, morever, which can be obtained, often restrict the architect to the use of pilasters, over which the projections of the entablature are not so great; indeed, as the author in the *Encyclopedie Methodique* ob-

serves, a pilaster may be considered as a column in bas-relief, and is thus, from the diminished quantity of labour and material in it, simpler and more economical in application. That in houses and palaces of the second class the decoration by pilasters is of great service may be amply shown, by reference to the works of Bramante, San Gallo, Palladio, and the other great masters of Italy, no less than in this country to those of Jones, Wren, and Vanbrugh.

2677. In profiling the capitals of Tuscan and Doric pilasters there can of course arise no difficulty; they follow the profiles of those over the columns themselves. In the capitals, however, of the other orders, some difficulties occur: these are thus noticed by Chambers. "In the antique Ionic capital, the extraordinary projection of the ovolo makes it necessary either to bend it inwards considerably towards the extremities, that it may pass behind the volutes, or, instead of keeping the volutes flat in front, as they commonly are in the antique, to twist them outwards till they give room for the passage of the ovolo. Le Clerc" (*Traité d'Architecture*) "thinks the latter of these expedients the best, and that the artifice may not be too striking, the projection of the ovolo may be considerably diminished, as in the annexed design" (*fig.* 923.), "which, as the moulding can be seen in front only, will occasion no disagreeable effect."

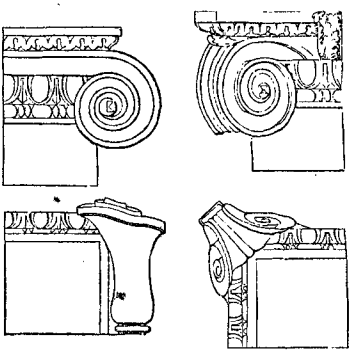

Fig. 923. Fig. 924.

2678. "The same difficulty subsists with regard to the passage of the ovolo behind the angular Ionic volutes. Le Clerc therefore advises to open or spread the volutes sufficiently to leave room for the ovolo to pass behind them, as in the design" (*fig.* 924.) "annexed; which may be easily done, if the projection of the ovolo is diminished. Inigo Jones has in the Banqueting House made the two sides of the volutes parallel to each other, according to Scamozzi's manner, and at the same time has continued the ovolo in a straight line under them, so that the volutes have an enormous projection; which, added to the other faults of these capitals, renders the whole composition unusually defective and exceedingly ugly."

2679. "What has been said with regard to the passage of the ovolo behind the volutes in the Ionic order is likewise to be remembered in the Composite; and in the Corinthian the lip or edge of the vase or basket may be bent a little inwards towards its extremities, by which means it will easily pass behind the volutes. The leaves in the Corinthian and Composite capitals must not project beyond the top of the shaft, as they do at San Carlo in the Corso at Rome, and at the Banqueting House, Whitehall; but the diameter of the capital must be exactly the same as that of the top of the shaft. And to make out the thickness of the small bottom leaves, their edges may be bent a trifle outwards, and the large angular leaves may be directed inwards in their approach towards them, as in the annexed design" (*fig.* 925.), "and as they are executed in the church of the Roman college at Rome. When the small leaves have a considerable thickness, though the diameter of the capital is exactly the same as that of the shaft, in each front of the Composite or Corinthian pilaster capital, there must be two small leaves with one entire and two half large ones. They must be either of olive, acanthus, parsley, or laurel, massed, divided, and wrought, in the same manner as those of the columns are, the only difference being that they will be somewhat broader."

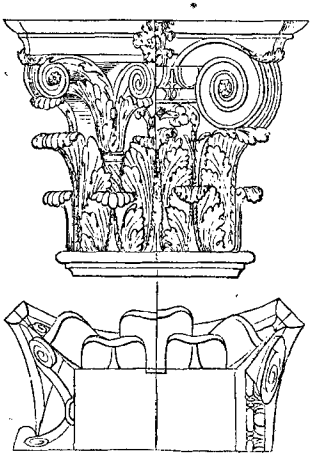

Fig. 925.

2680. It is desirable to avoid the use of pilasters at inward angles penetrating each other, because of the irregularity such practice produces in the entablatures and capitals. One break is quite as much as should be ever tolerated, though in many of the churches in Rome they are multiplied with great profusion of mutilated capitals and entablatures; "than which," observes Chambers, "nothing can be more confused or disagreeable."

2681. Neither should columns be allowed to penetrate each other, as they do in the court of the Louvre, inasmuch as the same irregularity is induced by it as we have also noticed in the case of pilasters.

Sect. XV.

CARYATIDES AND PERSIANS.

2682. The origin of caryatides we have in the First Book (165, *et seq.*) so far as regards our own opinions, explained, and in that respect we shall not trouble the reader. Our object in this section is merely to offer some observations on the use of them in modern practice. The figures denominated Persians, Atlantes, and the like, are in the same category, and we shall not therefore stop to inquire into their respective merits; indeed, that has already been sufficiently done in the book above alluded to. The writer of the article in the *Encyclopedie Methodique* has, we think, thrown away a vast deal of elegant writing on the subject of caryatides; and using, as we have done, to some extent, that extraordinary work, we think it necessary to say that we cannot recommend anything belonging to that article to the notice of the reader, except what is contained in the latter part of it, and with that we do not altogether agree.

2683. The object, or apparent object, in the use of caryatides is for the purpose of support. There is no case in which this cannot be better accomplished by a solid support, such as a column, the use of the attic order, or some other equivalent means. But the variety in quest of which the eye is always in search, and the picturesque effect which may be induced by the employment of caryatides, leads often to their necessary employment. The plain truth is, that they are admissible only as objects necessary for an extreme degree of decoration, and otherwise employed are not to be tolerated. There can, as we imagine, be no doubt that the most successful application of these figures as supports was by Jean Gougeon in the Louvre; as was the most unfortunate in the use of them in a church in the New Road, which at the time of its erection was much lauded, but which we hope will never be imitated by any British architect.

2684. As to the use of what are called Persians or male figures, originally in Persian dresses, to designate, as Vitruvius tells us, the victory over their country by the Greeks, the observations above made equally apply, and in the present day their application will not bear a moment's suspense in consideration.

2685. We have been much amused with the gravity wherewith Sir William Chambers, not with his usual sound sense, treats the claims of the personages whose merits we are discussing: he says, "Male figures may be introduced with propriety in arsenals or galleries of armour, in guard-rooms and other military places, where they should represent the figures of captives, or else of martial virtues; such as strength, valour, wisdom, prudence, fortitude, and the like." He writes more like himself when he says, "There are few nobler thoughts in the remains of antiquity than Inigo Jones's court" (in the design for the great palace at Whitehall), "the effect of which, if properly executed, would have been surprising and great in the highest degree." (See *fig.* 207.)

2686. What is called a *terminus*, which is, in fact, nothing more than a portion of an inverted obelisk, we shall not observe upon further than to say that it is a form, as applied to architecture, held in abhorrence. For the purpose, when detached and isolated, of supporting busts in gardens, it may perhaps be occasionally tolerated: further we have nothing to say in its favour. Those who seek for additional instruction on what are called termini, may find some account of them, as the boundary posts of land among the Romans, in books relating to the antiquities of that people.

2687. We shall now proceed to submit some examples of caryatides for the use of those whose designs require their employment. *Fig.* 926. is from a model of Michael Angelo

Fig. 926

Fig. 927

Fig. 928.

Fig. 929.

Buonarotti, and is extracted from the *Treatise on Civil Architecture*, by Sir William Chambers, as are the succeeding examples.

2688. *Figs.* 927. and 928. are also designs by Michael Angelo, which, though not designed for a building, are well adapted for the purpose under certain conditions.

2689. *Fig.* 929. is the design of Andrea Biffi, a sculptor of Milan, in the cathedral of which city it is one of the figures surrounding the choir. The statue possesses much grace, and was admirably suited to the edifice wherein it was employed.

2690. *Fig.* 930. comes from Holland, having been executed by Artus Quellinus in the judgment-hall of the Stadthouse at Amsterdam.

Fig. 930.

Fig. 931.

Fig. 932.

Fig. 933.

Fig. 934.

2691. *Fig.* 931. is by Michael Angelo, and is at the Villa Ludovisi at Rome.

2692. *Fig.* 932. is from the design by the last-named master for the monument of Pope Julius, whereof we have had occasion already to make mention in the First Book of this work. (335.)

2693. *Fig.* 933. is a representation of one of the celebrated caryatides by Jean Gougeon in the Swiss guard-room of the old Louvre at Paris, and does not deserve less admiration than it has received. The scale on which this and the preceding figures are given does not admit of so good a representation as we could wish.

2694. *Fig.* 934. is from the arch of the goldsmiths at Rome, being thereon in basso rilievo, but considered by Chambers as well as ourselves a suitable hint for carrying out the purpose of this section.

SECT. XVI.

BALUSTRADES AND BALUSTERS.

2695. A baluster is a species of column used as an ornamental railing in front of windows, or in arcades, or on the summit of a building, whose professed object is the protection of its inhabitants from accidents: analogously, too, it consists of a capital, shaft and base.

2696. The baluster is not found in the works of the ancients, and we believe it owed its introduction in architecture to the restorers of the arts in Italy, in which country a vast variety of examples are to be found. They made their first appearance in the form of stunted columns, not unfrequently surmounted by a clumsily-shaped Ionic capital. The term is said to have had its rise (with what truth we cannot pronounce) from the Latin *balaustium*, or the Greek βαλαυστιον, the flower of the wild pomegranate, to which in form the architectural baluster is said by some to bear a resemblance. The writer in the *Encyclopedie Methodique* has taken the opportunity, in the article "Balustre," of launching his anathema against the use of it, but we by no means agree with him; and instead of calling it, as he does, "*une invention mesquine*," we incline to think that it was almost the only invention of the modern architects that deserves our admiration. It is true that the form has been abused in every possible shape; but we are not, in art more than in morals, to arrive at the conclusion that anything is bad because it has been abused and misapplied. Such, then, being the case, we shall proceed in a serious vein to consider its proportions, founded on the best examples that have come to our hands. We must first premise with J. F. Blondel, that balusters and balustrades, which last are a series of the first, should in form and arrangement partake of the character of the edifice. They have even been in their species so subdivided as to be arranged under as many classifications as the orders themselves, a distinct sort having been assigned for employment with each order. We are not quite certain that such an arrangement is necessary, but are rather inclined to think it fanciful; though we are quite willing to allow that where the lighter orders are employed,

the balustrades to be used over them are susceptible of a more minute and lighter subdivision of their parts.

2697. The general rules to be observed in the use of the balustrade are, that its balusters be of an odd number, and that the distance between them should be equal to half their larger diameter, from which will result an equality between the open and solid spaces. Blondel disapproves of a half baluster on the flanks of a subdivision of a balustrade: in this we dissent from him, and would always recommend its adoption if possible. In respect of the detailed proportions of the balusters themselves, we are to recollect that the subdivisions are of the capital, the shaft or vase of the baluster, and its base. For proportioning these to one another, Chambers (and we think the proportions he uses not inelegant) divides the whole given height into thirteen equal parts, whereof the height of the baluster is eight, that of the base three, and of the cornice or rail two. If the baluster is required to be less, he divides the height into fourteen parts, giving eight to the baluster, four to the base, and two to the rail. He calls one of these parts a module for the measurement of the rest, and that measure we think convenient for adoption in this work. The module he divides into nine parts.

2698. Balusters intended for real use in a building, as those employed on steps or stairs, or before windows, or to enclose terraces, should not be less than three feet in height, nor more than three feet six inches; that is, sufficiently high to give security to the persons using them: but when merely used as ornamental appendages, as in crowning a building, they should bear some proportion to the parts of the building. Chambers says that their height never ought to exceed four fifths of the height of the entablature on which they are placed, nor should it ever be less than two thirds, without counting the zoccolo or plinth. the height of which must be sufficient to leave the whole balustrade exposed to view from the best point of sight for viewing the building. We can scarcely admit these rules to pass without noting the examples in Palladio's works, which give a much greater latitude for variety. When balusters fill in between the pedestals, as in the façade of the Palace Chiericato at Vicenza, the balustrade's height is of course regulated by that of the pedestal itself; but in the court of the Porti palace the crowning balustrade is not higher than the cornice of the entablature on which it stands. The same proportion is observed in the atrium of the Carità at Venice. In the Valmarana palace the height of the balustrade is equal to that of the entablature of the small order. It is true that in a few instances this master made the height of the balustrade equal to that of the whole entablature, and Inigo Jones has in some instances followed his example; but this was not the general practice either of the one or the other.

2699. We have already said that the baluster generally varies in form, so as to be appropriate to the order over which it is used. It is moreover to be observed that the baluster is susceptible of a pleasing variety of its form by making it square instead of circular on the plan, whereof examples are given in *figs.* 938, 939, and 940.; but when the situation requires an expression of solidity, almost all the circular examples we submit to the reader may be changed from a circular to a square form on the plan, and thus as required we may obtain the character suitable to their respective situations. These changes, from one to another form in details of this description, are in their adoption much more the index to the capacity and genius of the architect than the restless and capricious longing after variety recently exhibited in some of the latest works produced in the city of London, works which reflect no credit on the age in which we live. In *fig.* 935. is given a baluster

Fig. 935.

Fig. 936.

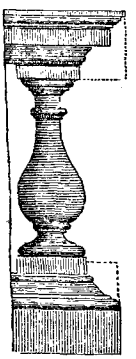

Fig. 937.

suitable to the Tuscan order; and using the module of nine parts above mentioned, the following is a table of its dimensions:—

	Members.	Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	3	27½
	Corona	8⅔	24⅓
	Quarter round	4⅔	
	Fillet	1⅔	
Baluster, 8 modules.	Abacus	5⅔	11½
	Cyma reversa	4	
	Neck	5	5¼
	Astragal } Fillet }	3⅓	
	Centre of belly	27	13
	From same to astragal	9	
	Astragal } Fillet }	2⅓	10½ fillet
	Inverted cyma	6⅓	
	Plinth	7⅓	13
Pedestal, 3 modules.	Inverted cavetto	5	
	Fillet	2	
	Astragal	5	
	Plinth	15	24

2700. In *fig.* 936. is given the form of a baluster suited to the Doric and Ionic orders, of which also the table of dimensions is subjoined: —

	Members.	Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	2	27
	Cyma reversa	3⅔	
	Corona	7	22
	Quarter round	4	
	Fillet	1⅓	
Baluster, 8 modules.	Abacus	5⅔	11
	Echinus	3⅓	
	Fillet	1	
	Neck	5	5
	Astragal } Fillet }	3	
	Centre of belly	27	12½
	From same to astragal	9	
	Astragal	2	
	Fillet	1	
	Inverted cavetto	6	10 (upper part)
	Fillet	2⅔	
	Plinth	7⅓	12½
Pedestal, 3 modules.	Fillet	1⅓	
	Inverted ogee	5	
	Fillet	1⅔	
	Astragal	4⅓	
	Plinth	15	23½

2701. A suitable baluster for the Corinthian or Composite order is exhibited in *fig.* 937., whereof the measures are as follow: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	1⅓	26⅓
	Echinus	2⅓	
	Fillet	1	
	Corona	6⅓	21½
	Cyma reversa	3⅓	
	Astragal and Fillet	2⅔	
Baluster, 8 modules.	Abacus	5	10⅓
	Echinus	3	
	Fillet and Cavetto	2⅓	
	Neck	5	4⅔
	Astragal and Fillet	2⅔	
	Centre of belly	27	12
	From same to astragal	9	
	Astragal and Fillet	2⅔	
	Scotia	4⅔	4⅔ (at top)
	Fillet	1	
	Astragal	3⅓	
	Plinth	6	12
Pedestal, 3 modules.	Fillet and Astragal	2⅔	
	Inverted cyma recta	4⅓	
	Fillet	1	
	Astragal	4	
	Plinth	15	23

2702. The Tuscan baluster (*fig.* 938.) is suitable for terraces and basements: its rail

Fig. 938.

Fig. 939.

Fig. 940.

Fig. 941

Fig. 942.

Fig. 943.

and pedestal may be the same height as in the *fig.* 935. Its principal measures being as follow: —

Members		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster 5 modules.	Abacus	3	6
	Cyma reversa	2	
	Neck and Fillet	4	3
	Rustic belly (at top)	27	4½
	Rustic belly (at bottom)		7½
	Bottom of belly and Fillet	2½	
	Inverted cavetto and fillet	8	3
	Plinth	8½	7½

Other forms of Tuscan balusters are given in *figs.* 939. and 940., but it is not necessary to give the detail of the parts, as the proportions are sufficiently preserved in the figures.

2703. The double-bellied baluster is used in situations where greater lightness is required from the smallness of the parts and the delicacy of the profiles. The proportions for the bases and rails need not vary from those already given. Perhaps they need not be quite so large.

2704. *Fig.* 941. is an example of a double-bellied baluster suitable to the Doric order. Its parts are as follow: —

Members.		Heights in Parts of a Module	Projections in Parts of a Module from Centre of Baluster.
Baluster, 8 modules.	Abacus	1/2	8
	Echinus and Fillet	1/2	
	Upper part	2 1/2	4 neck, 8 belly
	Middle part	1/2	6 centre
	Lower part	2 1/2	8 belly, 4 neck
	Fillet and Inverted echinus	1/2	
	Plinth	1/2	8

2705. In *fig.* 942. we give an example of the double-bellied baluster for the Ionic order, and its measures are subjoined: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 10 modules.	Abacus	1/2	9
	Fillet and cyma reversa	1/2	
	Upper part	3 1/2	4 1/2 neck, 9 belly
	Middle part	9	7 1/2 centre
	Lower part	3 1/2	9 belly, 4 1/2 neck
	Inverted cyma and fillet	1/2	
	Plinth	1/2	9

2706. The last example we shall give of the double-bellied baluster (*fig.* 943.) is suitable to the Corinthian order. The measures are as follow: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 12 modules.	Abacus	5	11
	Echinus and fillet	4	
	Neck	5 1/2	5 1/2
	Astragal and fillet	3 1/2	
	Upper part	29	5 1/2 at top, 11 at belly
	Middle	6	
	Lower part	29	11 at belly, 5 1/2 at bottom
	Fillet and astragal	3 1/2	
	Neck	5 1/2	5 1/2
	Fillet and inverted echinus	4	
	Plinth	5	11

2707. We do not deem it necessary to give any examples of the scroll and Guiloche balustrades, which were so much in vogue during the reigns of Louis XIV. and Louis XV., though the present taste seems almost to require it. As that taste has been mainly generated by house decorators, as they are called, and upholsterers, these gentry will soon find out another means of amusing the public, by driving them out of fashion and finding all that is beautiful in some renovated and equal absurdities.

2708. We have already observed that the intervals between balusters should not be more than half the diameter of the baluster at its thickest part; to this we may here add, that they should not be less than one third of that diameter. The pedestals for supporting the rail ought neither to be too frequent nor too far apart; for in the first case they impart a heavy appearance to the work, and in the last the work will seem weak. Seven or nine balusters are good numbers for a group, besides the two half ones engaged in the pedestals. The disposition, however, and number of the pedestals depend on the places below of the piers, columns, or pilasters, for over these a pedestal must stand; and when, therefore, it happens that the intervals are greater than are required for the reception of nine balusters, the distance may contain two or three groups each, flanked with half balusters, and the width of the dies separating the groups may be from two thirds to three quarters the width of the principal pedestals. The rail and base should not be broken by projections, but run in unbroken lines between the pedestals.

2709. When the principal pedestals stand over columns or pilasters, their dies should not be made wider than the top of the shafts, and on no account narrower; indeed, it is better to flank them on each side when the ranges are long with half dies, and give a small projection to the central pedestal, and to let the base and rail follow the projection in their profiles. This practice will give real as well as apparent solidity to the balustrade.

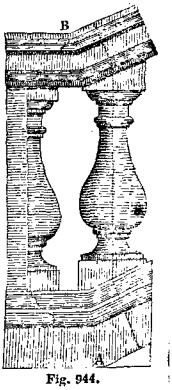

Fig. 944.

2710. *Fig.* 944. shows the application of a balustrade to a portion of a staircase, and herein the same proportions are observed as on level ranges. Some masters have made the mouldings of the different members of the baluster, follow the *rake* or inclination of the steps; but the practice is vicious: they should preserve their horizontality, as exhibited in the figure, in which, at A and B, is also shown the method in which the horizontal are joined to the inclined mouldings of the base and rail. In the balustrades of stairs the spaces between the balusters are usually made narrower than they are on level beds; and Le Clerc recommends that the height of the plinth should be equal to that of the steps; but this is not absolutely required, though it must on no account be less.

2711. The bulbs or bellies of balusters and their mouldings may be carved and otherwise enriched: indeed, in highly decorated interiors, this seems requisite.

2712. The following observations as to the height of statues placed upon balustrades are from Sir William Chambers: — "When statues are placed upon a balustrade their height should not exceed one quarter of the column and entablature on which the balustrade stands. Their attitudes must be upright, or, if anything, bending a little forwards, but never inclined to either side. Their legs must be close to each other, and the draperies close to their bodies, for whenever they stand straddling with bodies tortured into a variety of bends, and draperies waving in the wind, as those placed on the colonnades of St. Peter's, they have a most disagreeable effect, especially at a distance, from whence they appear like lumps of unformed materials, ready to drop upon the heads of passengers. The three figures placed on the pediment of Lord Spencer's house, in the Green Park, which were executed by the late ingenious Mr. Spang, are well composed for the purpose."

2713. "The heights of vases placed upon balustrades should not exceed two thirds of the height given to statues," says the same author. We are not altogether averse to the application of either statues or vases in the predicated situations, but we think the greatest discretion is required in their employment. When it is necessary to attract the eye from an indispensably obtrusive roof, they are of great value in the composition; but we shall not further enter on this point of controversy, for such it is, inasmuch as many object to their use altogether, and have considerable reason on their side. We must, however, briefly state the ground of objection, and Chambers's answer as respects statues. There are, he says, some "who totally reject the practice of placing statues on the outsides of buildings, founding their doctrine, probably, upon a remark which I have somewhere met with in a French author, importing that neither men, nor even angels or demi-gods, could stand in all weathers upon the tops of houses or churches."

2714. "The observation is wise, no doubt," (we doubt the wisdom of it,) "yet, as a piece of marble or stone is not likely to be mistaken for a live demi-god, and as statues, when properly introduced, are by far the most graceful terminations of a composition, one of the most abundant sources of varied entertainment, and amongst the richest, most

durable, and elegant ornaments of a structure, it may be hoped they will still continue to be tolerated." We fear that if the only reasons for their toleration were those assigned by the author, their doom would soon be sealed.

SECT. XVII.

PEDIMENTS.

2715. A pediment, whose etymology is not quite clear, consists of a portion of the horizontal cornice of the building to which it is applied, meeting two entire continued raking cornices, and enclosing by the three boundaries a space which is usually plain, called the *tympanum*. It is not, however, necessary that the upper cornice should be rectilinear, inasmuch as the cornice is sometimes formed by the segment of a circle. The arrangement in question was the Roman *fastigium*, and is the French *fronton*. The Greeks called pediments *αετοι*, or eagles; why, this is not the place to inquire. The origin of the pediment, according to authors, seems to have arisen from the inclined sides of the primitive hut. This is a subject, however, which in the First Book (subsec. 5.) has been already considered, and we shall therefore in this section confine ourselves to its employment in the architecture of the day.

2716. Of the varied forms which, by masters even of acknowledged talent, have been given to the pediment, whether polygonal, with curves of contrary flexure, with mixed forms, broken in the horizontal part of the cornice or in the raking parts of it, or reversed in its office with two springing inclined sides from the centre, we propose to say no more than that they are such abuses of all rules of propriety, that we shall not further notice them than by observing that in regular architecture no practice is to be tolerated where the pediment is composed otherwise than of two raking unbroken and one horizontal unbroken cornice, or of the latter and one continued flexure of curved line. To these only, therefore, we now apply ourselves.

2717. Generally, except for windows and doors, the pediment ought not to be used, but as a termination of the whole composition; and though examples are to be found without number in which an opposite practice has obtained, the reader, on reflection, will be convinced of the impropriety of it, if there be the smallest foundation for its origin in the termination of the slant sides of the hut.

2718. The use of the pediment in the interior of a building is, perhaps, very questionable, though the greatest masters have adopted it. We think it altogether unnecessary; if the pyramidal form is desirable for any particular combination of lines, it may be obtained by a vast number of other means than that of the introduction of the pediment. Hence we are of opinion that the attempted apology for them in Sir William Chambers's work, is altogether weak and unworthy of him, and only to be explained by that master's own practice.

2719. Vitruvius ordains that neither the modillions nor dentils which are used in the horizontal cornice should be used in the sloping cornices of a pediment, inasmuch as they represent parts in a roof which could not appear in that position: and the remains generally of antiquity seem to bear him out in the assertion; but the Roman remains seem to bear a different testimony to the validity of the law, and to our own eyes the transgression affords pleasure, and we should recommend the student not to feel himself at all bound by it; for, as Chambers most truly observes, "The disparity of figure and enrichment between the horizontal and inclined cornices are such defects as cannot be compensated by any degree of propriety whatever, and therefore to me it appears best, in imitation of the greatest Roman and modern architects, always to make the two cornices of the same profile, thus committing a trifling impropriety to avoid a very considerable deformity."

2720. Different sized pediments in the same façade are to be avoided; but as respects their forms in ranges of windows and niches a pleasing variety is often obtained by making them alternately curved and rectilinear, as in the temple at Nismes and in the niches of the Pantheon at Rome.

2721. In the horizontal part of a cornice under a pediment the two upper mouldings are always omitted, and the intersection of the inclined with the horizontal lines, supposing the inclined members of the cornice to be of the same height as those which are horizontal, will not fall into the profile (*fig.* 945.) whereof AB and BC are the leading lines. To obviate this inconvenience, some architects have made a break in the cymatium and fillet, as shown

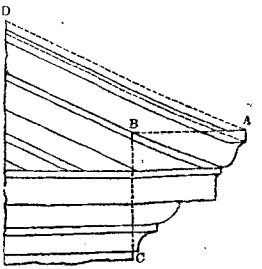

Fig. 945.

in the figure. But this is a bad practice, and to it we prefer either making the cyma and fillet higher, as the dotted line AD indicates, or altogether lowering the height of the cyma on the horizontal line If the inclined cornice is joined on each side by horizontal ones, the best expedient is to give only such small projection to the cyma as that it may meet the inclined sides.

2722. The heights of pediments should be regulated by their lengths, independent of the consideration of climate. (See Book II. Chap. III. Sect. IV. 2027.) Thus, when the base of the pediment is short, the height of the pediment may be greater; and when long, it should be diminished; for in the former case the inclined cornice leaves but scanty space for the tympanum, and in the latter case the tympanum will appear overcharged. From one fifth to one quarter of the length appears to have been agreed on as the limits; but we subjoin, from a work by Stanislas L'Eveillé (*Considerations sur les Frontons*, 4to. Paris, 1824), the method which we consider the best for determining the height of a pediment, observing, by the way, that a strict adherence to the ordinary rules for finding the height may produce the absurdity of a pediment higher than the columns by which it is borne, a condition which would not at all accord with the view we have taken of the orders in Sect. II.

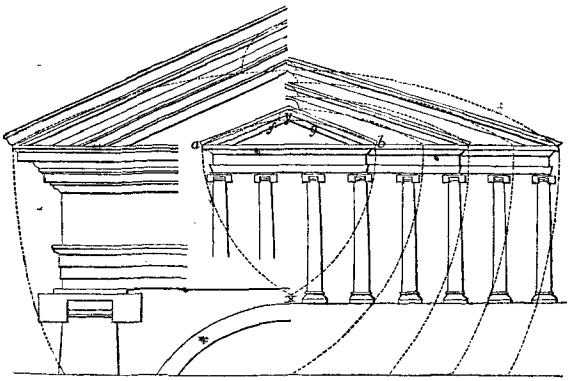

Fig. 946.

Chap. 1. of this Book. In fig. 946. we have a synoptical view of pediments of various extents, and as the letters applied to the central pediment will apply to all the rest, we shall restrict our description to that. Suppose the points *a* and *b* to be the extremities of the fillet of the corona. Then, with a radius equal to *ab*, from the points *a* and *b*, describe the arcs *ax*, *bx*, and from their intersection *x* with the same radius let the arc *ayb* be described. From *y*, as a centre, with a radius equal to the height of the horizontal part of the cornice, describe the portion of the circle *f g*, and from *a* and *b* draw thereto tangents intersecting in *y*. Then *yb* and *ya* will be the proper inclination of the fillet of the corona to which the other members of the inclined parts will necessarily be parallel.

2723. We conclude this section by the words of Chambers. "The face of the tympan is always placed on a line perpendicular with the face of the frieze; and when large, may be adorned with sculpture, representing the arms or cypher of the owner, trophies of various kinds, suited to the nature of the structure, or bas-reliefs, representing either allegorical or historical subjects; but when small it is much better left plain."

Sect. XVIII.

CORNICES.

2724. In many cases the façades of buildings are erected without any of the orders appearing in the design, other, perhaps, than those which are applied as the dressings of windows, niches, or doors. The palaces of Florence and Rome abound with such examples, in most of which the edifice is crowned with a cornice, which adds dignity to the building, producing a play of light and shadow about it of the utmost importance as regards its picturesque effect. The moderns have generally failed in this fine feature of a building; and it is only within the last few years, in this country, that a return to the practice of the old masters, a practice properly appreciated by Jones, Wren, Vanbrugh, and Burlington, has manifested itself. If a building be entirely denuded of pilasters and columns, and there are very few common instances that justify their introduction, it seems rational to

deduce the proportion of the height and profile of its cornice from the proportions that would be given to it if an order intervened.

2725. If we consider the height of the crowning cornice of a building in this way, and as the portion of an entablature whose height is, as in the case of an order, one fifth of that of the building, we should immediately obtain a good proportion by dividing the whole height into 25 parts and giving two of them to the height of the cornice. For the entablature being one fifth of the whole height, and its general division being into 10 parts, four whereof are given to the cornice, we have for its height the $\frac{4}{10}$ of $\frac{1}{5} = \frac{4}{50} = \frac{2}{25}$, or the twelfth and a half part of the total height of the building $= 0{\cdot}08$. Now there are circumstances, such as when the piers are large, and in other cases when the parts are not very full in their profiles, which may justify a departure from the strict application of this rule; but it will be seen that in the following ten well-known examples the practice has not much differed from the theory, nearly the greatest deviation being in the celebrated cornice of the Farnese palace, which is here placed (*fig.* 947.) as an extraordinary work of art in connection with the building it crowns. The examples alluded to are as follow, and we shall begin with those of earlier date, the diminution in height being almost a chronological table of their erection, with the exception of those by Palladio:—

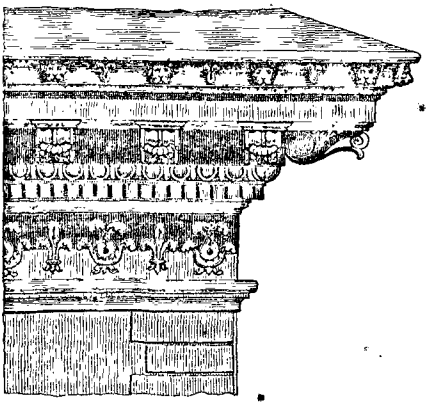

Fig. 947.

In the Spannocchi palace, at Siena, the cornice is $\frac{81}{1000}$ of the whole height of building, or $\frac{3}{37} = 0{\cdot}081$.

In the Picolomini palace, at Siena, the cornice is $\frac{74}{1000}$ of the whole height of building, or $\frac{2}{27} = 0{\cdot}074$.

In the Pojana palace, built by Palladio, at Pojana, in the Vicentine territory, the cornice is $\frac{71}{1000}$ of the whole height of building, or $\frac{1}{14} = 071$.

In the Strozzi palace, at Florence, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = 0{\cdot}069$.

In the Pandolfini palace, at Florence, by Raffaelle, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = 0{\cdot}069$.

In the Villa Montecchio, by Palladio, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = 0{\cdot}069$.

In the Villa Caldogno, by Palladio, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = 0{\cdot}069$.

In another villa by Palladio, for the family of Caldogno, the cornice is $\frac{66}{1000}$ of the whole height of building, or $\frac{1}{15} = 0{\cdot}066$.

In the Farnese palace, at Rome, the cornice is $\frac{59}{1000}$ of the whole height of building, or $\frac{1}{17} = 0{\cdot}059$.

In the Gondi palace, at Florence, the cornice is $\frac{57}{1000}$ of the whole height of building, or $\frac{2}{35} = 0{\cdot}057$.

From these examples it appears that the mean height of the cornices under consideration is something more than one fifteenth of the height of the building, and experience shows that, except under particular circumstances, much more than that is too great, and much less too little, to satisfy an educated eye. The grace beyond the reach of art is, if we may use an Hibernicism, in the power of few, but the bounds have been passed with success, as is testified in the Farnese palace. It may be objected to the system that we have generally adopted in this work, that we are too much reducing the art to rules. But this is a practice of which the painter is not ashamed in the proportions of the human figure, and we must remind our reader and the student that all rules are more for the purpose of restraining excess than bounding the flights of genius.

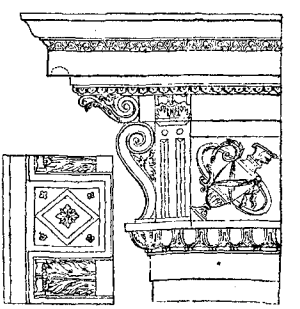

Fig. 948.

2726. *Fig.* 948. is an entablature by Vignola, which possesses great beauty, and has been often imitated in various ways for crowning a building; this must be con-

sidered more in relation to a building than a mere cornice, and requires rustic quoins, if possible, at the angles when used. Chambers, speaking of this example, says, that "when it is used to finish a plain building, the whole height is found by dividing the height of the whole front into eleven parts, one of which must be given to the entablature, and the remaining ten to the rest of the front." We suspect that the smallness which is assigned by this author to its height has been induced by some error, and that a better rule would be induced by assigning to the cornice its proper height, according to the laws above hinted at, and proportioning the rest of the entablature from the cornice thus obtained.

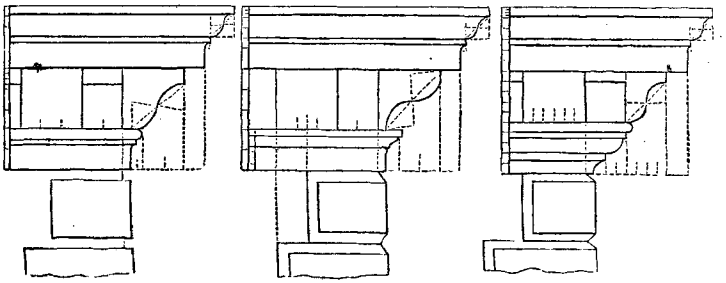

Fig. 951. Fig. 950. Fig. 949.

2727. In *figs.* 949, 950, and 951. are given three examples of block cornices (the second being by Palladio), whose proportions the figures sufficiently show without here giving a detail of their parts. The height of either should not be less than one fifteenth of the height of the building.

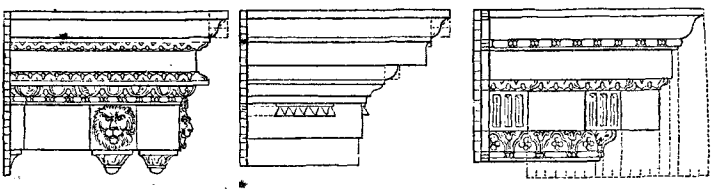

Fig. 952. Fig. 954. Fig. 953.

2728. *Figs.* 952. and 953. are block cornices, which we have adopted from Chambers, the first being from a palace at Milan, and the other, by Raffaelle, in a house in the Lungara at Rome. The height of these, says the author, and we agree with him, need not exceed one sixteenth part of the whole front, nor should either be less than one eighteenth. *Fig.* 954. is what is called an architrave cornice, which was frequently employed by the old masters. It seems well adapted to the entablatures of columns bearing arches, being rather in the nature of an impost; but it is useful, changing it to suit the order in cases where the height does not admit of the whole of the entablature being used over the order.

Sect. XIX

PROFILES OF DOORS.

2729. One of our objects in this work has been to impress throughout on the minds of our readers that architecture does not depend on arbitrary laws; and though we may not have proved satisfactorily to the student that the precise laws have been exactly stated, we trust we have exhibited sufficient to show and convince him that there was a method and limit in the works of the ancients which in the best times prevented the artists from falling on either side into excess.

2730. In *fig.* 955. we give a door with its architrave, frieze, and cornice, without relation to mouldings, but merely considered in the masses. Its proportions correspond with those most usually adopted; that is, its height is twice its width, the entablature is one fourth of the height of the opening, and the architraves on each side, together, two sixths of the width. The opening, therefore, measuring it in terms of the width of the architrave, will be 6 parts wide and 12 high, and its area consequently 72 parts. Now

it will be found that the solid parts of this are exactly on their face two thirds of this area; for up to the top of the opening each architrave being equal to 12, the sum will be 24; and the entablature being 8 wide and 3 (one fourth of twelve) high, $8 \times 3 = 24$; which added to 24 for the architraves gives 48 for the solids, and $\frac{48}{72} = \frac{2}{3}$, as above stated. The same analogy does not seem to hold in respect of doors and windows, of making the voids equal to the supports and weights, as in intercolumniations; nor indeed ought we to expect to find it, for the conditions are totally different, inasmuch as no door can exist except in a wall, whereas the office of columns is connected with the weight above only. We trust, therefore, we have shown enough to keep the reader's mind alive to some such law as above developed, without insisting very strongly on a minute attention to it in detail.

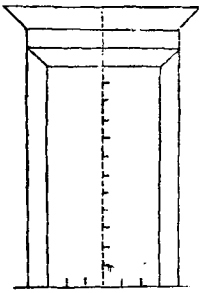

Fig. 955.

2731. We shall now, before submitting any examples of doorways to the reader, touch upon some important points that must be attended to; the first of which is, that all gates and doors, independent of all other considerations, must be of sufficient size for convenient passage through them. Hence internal doors must never be reduced under 2 feet 9 or 10 inches, and their height must not be under 6 feet 10 inches or 7 feet, so as to admit the tallest person to pass with his hat. These are minimum dimensions for ordinary houses in the principal floors; but for houses of a superior class, which are provided with what may be called state apartments, widths of 4, 5, and 6 feet, folding doors and the like, will not be too great for the openings, and the heights will of course be in proportion. The entrance doors of private houses ought not to be under 3 feet 6 inches, nor ordinarily more than 6 feet in width; but in public buildings, where crowds of people assemble, the minimum width should be 6 feet, and thence upwards to 10 or 12 feet. No gate should be less than 9 feet wide; and when loaded waggons or carts are to pass through it, 11 or 12 feet will not be too much. As a general observation we may mention that all doors should open inwards, for otherwise the person entering pulls the door in his face, which is an inconvenient mode of entering a room. Also when the width of a door is greater than 3 feet 8 inches it should be formed in two flaps, by which three advantages accrue: first, that the door will not occupy so much space for opening; second, that each door will be lighter; and, third, that the flaps will more nearly fold into the thickness of the wall. Chambers properly says, "That in settling the dimensions of apertures of doors regard must be had to the architecture with which the door is surrounded. If it be placed in the intercolumniation of an order, the height of the aperture should never exceed three quarters of the space between the pavement and the architrave of the order; otherwise there cannot be room for the ornaments of the door. Nor should it ever be much less than two thirds of that space, for then there will be room sufficient to introduce both an entablature and a pediment without crowding; whereas if it be less it will appear trifling, and the intercolumniation will not be sufficiently filled. The apertures of doors placed in arches are regulated by the imposts, the top of the cornice being generally made level with the top of the impost; and when doors are placed in the same line with windows, the top of the aperture should be level with the tops of the apertures of the windows; or if that be not practicable without making the door much larger than is necessary, the aperture may be lower than those of the windows, and the tops of all the cornices made on the same level."

2732. To say that the principal door of a building should if possible be in the centre of the front would seem almost unnecessary; but it is not so, perhaps, to inculcate the necessity of its being so situated in connection with the internal arrangement of the building as to lead with facility to every part of it, being, as Scamozzi observes (Parte Secunda, lib. vi. c. 4.), like the mouth of an animal placed in the middle of the face, and of easy communication with the *inside*. In the internal distribution the doors should as much as possible be opposite one another on many accounts, not the least whereof is the facility thus given to ventilation; but such a disposition also gives the opportunity of a far better display of a series of rooms, which on occasions of fêtes imparts great magnificence to the apartments. In this climate it is well to avoid too great a number of doors, and they should never, if it can be avoided, be placed near chimneys, because of subjecting to draughts of air those who sit near the fire. Generally the doors in a room should be reduced to the smallest number that will suit the distribution, and the practice of making feigned or blank doors, though sometimes necessary, should if possible be excluded.

2733. The ornaments with which doors are decorated must of course depend on the building in which they are used; and as this is a matter in which common sense must direct the architect, it is hardly necessary to say that the ornaments applied to them in a theatre would ill suit a church.

2734. The composition and designing of gates and their piers must of necessity suit the occasion, as well as the folding gates attached to them, for the enclosure of the parks,

gardens, and other places they are to serve. There are few finer examples in the higher class of this species of design than the celebrated gates at Hampton Court.

2735. The evil days on which we have fallen in this country, in respect of the arts, precludes the hope of again seeing the doors of our buildings ornamented with bassi relievi and bronze ornaments, a practice common among the ancients no less than among the revivers of the arts; witness the doors of St. Peter's, and, above all, those monuments of the art, the doors of the baptistery at Florence by Lorenzo Ghiberti, wherein art rises by being made only subservient to the holy purpose to which it is the mere handmaid. In the mention of doors those of San Giovanni Laterano at Rome must not be omitted; they have the credit of having been the enclosures to the temple of Saturn in the ancient city.

2736. The manufacture of doors has been already sufficiently noticed in the Second Book; and it therefore only remains for us to subjoin a few examples, which, we think among many others, deserve the attention of the student.

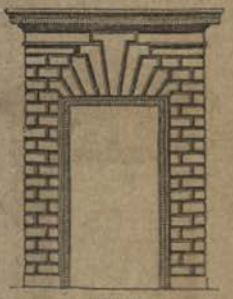

Fig. 957.

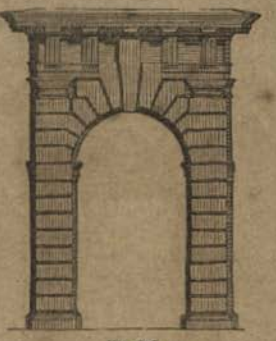

Fig. 956.

Fig. 958.

2737. Fig. 956. is an external doorway designed and executed by Vignola, at Caprarola, not a great distance north of Rome; it must speak for itself: if the reader be of our mind, he will see in it a beautiful handling of the subject; but we cannot further answer for our opinion, knowing as we do that some of the reviewers of these days may find out that it possesses no *æsthetic* beauties. There are cases where imitation has been permitted; and the sanction for our opinion is, that it has been imitated by one whom we and all others hold in reverence at Greenwich Hospital, though, as we think with Chambers, for the worse. "The aperture is in the form of an arch, and occupies somewhat more than two thirds of the whole height. It is adorned with two rusticated Doric pilasters and a regular entablature. The height of the pilasters is 16 modules, that of the entablature 4. The width of the aperture is 7 modules, its height 14, and the breath of each pier is 3 modules." To the detail of Chambers we have to add that the void in this example, which has no analogy to that which as a general rule we gave in the commencement of the section, is about one third of the area of the whole design, the void being to such area as 7·57 to 20·88.

2738. *Fig.* 957. is a design by the last-mentioned master, in which the void is as nearly as possible equal to one third of the area, the supports another, and the weights the other third: in other terms, the aperture occupies two thirds of the whole height and one half of the whole breadth, being, in fact, a double square. Its entablature has an alliance with the Tuscan order, and the cornice is equal to one fifteenth of the whole height of the door. These two examples are especially external; those which follow are from their nature applicable in general form to either external or internal doorways.

2739. *Fig.* 958. is a doorway in the Cancellaria at Rome, and is from the design of Vignola. The width is one half the height, and the height of the entablature is equal to one third of the height of the aperture. The breadth of the architrave is one fifth of the aperture's width, and the pilasters below the consoles are half as broad as the architrave. It is heavy, as might have been expected from the proportion between the voids and the solids.

2740. *Fig.* 959. is a design by Michael Angelo Buonarotti, and its aperture may be twice its height,

Fig. 959.

Fig. 960.

the whole entablature a quarter of its height, and the architrave one sixth of the width of the aperture. The face of the pilasters or columns at the sides must be regulated by the lower fascia of the architrave, and their breadth is to be a semidiameter.

2741. *Fig.* 960. is by Vignola, and is in the Farnese palace at Rome. The opening is twice the width in height, and the entablature is three elevenths of the height of the aperture, one of the foregoing elevenths being given to the architrave. The whole of the ornament on the sides is, including architraves and pilasters, equal to two sevenths of the width of the aperture. The cornice is Composite, with modillions and dentils, and the frieze is enriched with a laurel band.

2742. *Fig.* 961., another of the examples given by Chambers, is believed to be by Cigoli. The void is rather more in height than twice its width. The impost of the arch is equal to half a diameter, the columns are rather more than nine diameters high, and rusticated with five square cinctures. The entablature is not so much as one quarter of the height of the column, and its tablet is equal to the width of the aperture.

Fig. 961.

Fig. 962.

Fig. 963.

2743. *Fig.* 962. is by Inigo Jones, and the aperture may be twice as high as it is wide. The architrave may be a sixth or seventh of the width of the aperture, the top of it being level with the astragal of the columns, which are Corinthian, and ten diameters in height. They must be so far removed on each side from the architrave as to allow the full projection of their bases. The entablature may be from two ninths to one fifth of the column, and the pediment should be regulated by the rules given in Sect. XVII. (2722.).

2744. *Fig.* 963. is by Serlio. The aperture may be a double square, or a trifle less; the diameter of the columns a quarter of the width of the aperture, or a trifle less; their height 8 to 8½ diameters; the entablature about a quarter of the height of the columns, and the pediment should be drawn in conformity with the directions in Sect. XVII.

SECT. XX.

WINDOWS.

2745. Windows, of all the parts of a building, are those which require the greatest nicety in adjustment between the interior and exterior relations of them. The architect who merely looks to the effect they will produce in his façades has done less than half his work and deserves no better name or rank than that of a mere builder. It seems almost useless to observe that the windows of a building should preserve the same character, that those in each story must be of the same height, and that the openings must be directly over one another. Blank windows are, if possible, to be avoided: they always indicate that the architect wanted skill to unite the internal wants of the building with its external decoration. Windows, moreover, should be as far removed as the interior will permit from the quoins of a building, because they not only apparently, but really, weaken the angles when placed too near them.

2746. Vitruvius, Palladio, Scamozzi, and Philibert de l'Orme, besides many other masters, have given different proportions to them as connected with the apartments to be lighted. That these should be different is indicated by the different places in which those masters have written. Nothing, indeed, seems so much to disallow general laws as the proportion of windows to an apartment; according to the climate, the temperature, the

length of the days, the general clearness of the sky, the wants and customs of commerce and of life generally. In hot climates the windows are always few in number and small in dimension. As we approach those regions where the sun has less power and the winter is longer, we observe always an increase in their size and number, so as to enable the inhabitants to take as much advantage as possible of the sun's light and rays. It seems, therefore, almost impossible to give general rules on this subject. We shall on this account endeavour, in the rules that this section contains, to confine ourselves to the sizes which seem suitable in this climate, as respects the proportion of light necessary for the comfort of an apartment.

2747. It is a matter of experience that the greatest quantity of light is obtained for an apartment when lighted by an horizontal aperture in the ceiling. Of this a very extraordinary verification is to be found in the Pantheon at Rome. This edifice, whose clear internal diameter is 142 feet 6 inches, not including the recesses behind the columns, is nearly 74 feet high to the springing of the dome, which is semicircular. The total clear number of cubic feet in it may therefore be taken in round numbers at 1,934,460 cubic feet. Those who have visited it well know that it is most sufficiently and pleasingly lighted, and this is effected by an aperture (the *eye*, as it is technically called,) in the crown of the dome, which aperture is only 27 feet in diameter. Now the area of a circle 27 feet in diameter being rather more than 572 feet, it follows that each superficial foot of the area lights the astonishing quantity of nearly 3380 cubic feet. Independent of all considerations of climate, this shows the amazing superiority of a light falling vertically, where it can be introduced. But in a majority of cases the apertures for light are introduced in vertical walls; and the consequence is, that a far greater area of them for the admission of light becomes necessary. In considering the question it must be premised that a large open space is supposed before the windows, and not the obstructed light which it is the lot of the inhabitants of closely-built streets to enjoy. Again, it is to be recollected that in the proportioning of windows it is the apartments on the principal floor that are to be considered, because their width in all the stories must be guided by them, the only variety admissible being in the height. In this country, where the gloom and even darkness of wet, cloudy, and foggy seasons so much prevails, it is better to err on the side of too much rather than too little light, and when it is superabundant to exclude it by means of shutters and blinds. We are not very friendly to the splaying of windows, because of the irregularity of the lines which follows the practice; but, it must be admitted, it often becomes necessary when the walls are thick, and in such cases a considerable splay on the inside increases the light in effect by a great diminution of shade. It is well, if possible, to have an odd number of windows in an apartment: nothing wherein contributes more to gloom than a pier in the centre.

2748. We do not think it necessary to advert to the rule of Palladio for the dimensions of windows given in the first book of his work, chap. 25.; because, were it true for the climate of northern Italy, it would not be so for that of Great Britain; neither are we at all satisfied with that which in his practice Sir William Chambers says he adopted, and which is as follows, in his own words:—"I have generally added the depth and height" we suppose width "of the rooms on the principal floor together, and taken one eighth part thereof for the width of the window; a rule to which there are few objections: admitting somewhat more light than Palladio's, it is, I apprehend, fitter for our climate than his rule would be." This rule is empirical, as indeed is that on which we place most dependence, and to which we shall presently introduce the reader, being ourselves inclined to the belief that in the lighting a room there is a direct relation between the area of the aperture admitting the light and the quantity of cube space in the room. Indeed the law which we are about to give is one founded on the cubic contents of the apartment; and if the results bore a regular ratio to that quantity, the discussion would be at an end, for we should then have only to ascertain the cubic contents, and, knowing how much an area of light one foot square would illuminate, the division of one by the other would supply the superficies of windows to be provided. Our own notion on this subject is, that 1 foot superficial of light in a vertical wall, supposing the building free from obstruction by high objects in the neighbourhood, will in a square room be sufficient for 100 cube feet if placed centrally in such room. It will, however, immediately occur to the reader, that this rule cannot in many cases satisfy the requirements of an apartment as respects the quantity of light necessary for its proper illumination. The subject is beset with numerous difficulties, which to overcome requires the greatest skill. In the case of an apartment, long as compared with its width, it is well known to every practical architect that windows of the same collective area at either of the narrow ends of such apartment will light it much more effectively than if the same area of light were admitted on either of the long sides, and most especially so, if it should happen that on such long side there were a pier instead of a window in the centre of such side. In illustration of what we mean, let us refer the reader to the ball room at Windsor Castle, an apartment 90 feet long, 34 feet wide, and 33 feet high. This room is lighted from the northern narrower side by a window nearly occupying the

width, and is supplied by an abundance of light. But had the same quantity of light been admitted from either of the long sides of the room, so many masses of shadow would have been introduced through the interposition of piers, that its effect would have differed most widely from the cheerful and airy aspect it now presents. We have taken this as an example that more presently occurs to us, but the reader from his observation will have no difficulty in supplying instances in corroboration of our impressions on this subject.

But we shall now proceed to give, in the author's own words, the rules of which we have spoken. That author is Robert Morris, and the work quoted is *Lectures on Architecture, consisting of Rules founded on Harmonick and Arithmetical Proportions in Building.* London, 8vo. 1734. "There are rules, likewise, for proportioning of light according to the magnitude of the room by which any room may be illuminated, more or less, according to the uses of them, and at the same time preserve an external regularity; which, as it is on an uncommon basis, I shall explain to you as well as I conveniently can. Let the magnitude of the room be given, and one of those proportions I have proposed to be made use of or any other; multiply the length and breadth of the room together, and that product multiply by the height, and the square root of that sum will be the area or superficial content in feet, &c. of the light required."

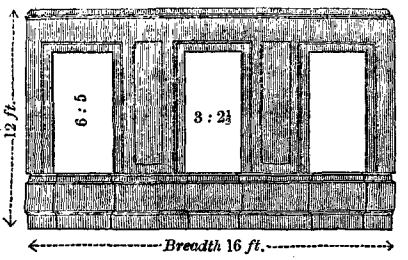

Fig. 964.

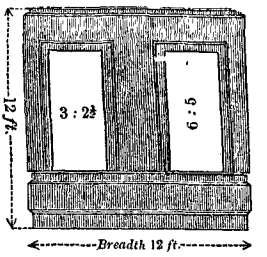

Fig. 965.

2749. "Example. Suppose a room (*fig.* 964.), whose magnitude is the arithmetical proportion of 5, 4, and 3, and is 20 feet long, 16 feet broad, and 12 feet high, the cube or product of its length, breadth, and height multiplied together is 3840, the square root of which sum is 62 feet. If the height of the story is 12 feet as before mentioned, divide that 62 feet into three windows; each window will contain 20 feet 8 inches of superficial light, and those will be found to be 6 feet 2½ inches broad, and 6 feet 5 inches high, which are windows of two diameters."

2750. "Let us now suppose another room on the same range whose height is 12 feet, as the preceding example is, and its proportion (*fig.* 965.) shall be the cube. The product of that cube is 1728, and its root is 41 feet 4 inches, or thereabouts: divide that 41 feet 4 inches in two parts for two windows, and each will be 20 feet 8 inches of superficial light, and those will be two diameters in height, and the magnitude the same as the preceding room."

2751. "For example sake, I will only suppose one more room (*fig.* 966) upon the same range, and 12 feet in height, whose proportion shall be the arithmetical of 3, 2, and 1; that is, its height being 12 feet, the breadth will be 24 and length 36, the product of those numbers multiplied together will be 10368, and its root 101 feet 8 inches, or thereabouts: divide this room into five windows, each window will have 20 feet 4 inches superficial light, and the magnitude will be near or equal to the others, and if the proportion be 6, 4, and 3, and coved, the light is the same."

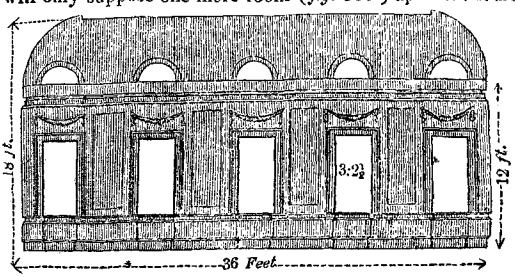

Fig. 966.

2752. "There is," says the author, rather perhaps simply, "but one objection to this rule to make it universal for all kinds of proportioned rooms on the same floor, and that is, the square root doth not always happen to be exact enough for to make them alike; but as the variation will be so small, it may be made use of; and if the area something exceeds the standard of the principal room, that room may be converted to a use which requires more than standard light, and the necessities of families sometimes require it. But, however, the rule will serve for the purpose near enough for any practice."

2753. "If you extend the rule to larger rooms, the same methods will be preserved even if the height be continued through two stories, if the upper windows be made square,

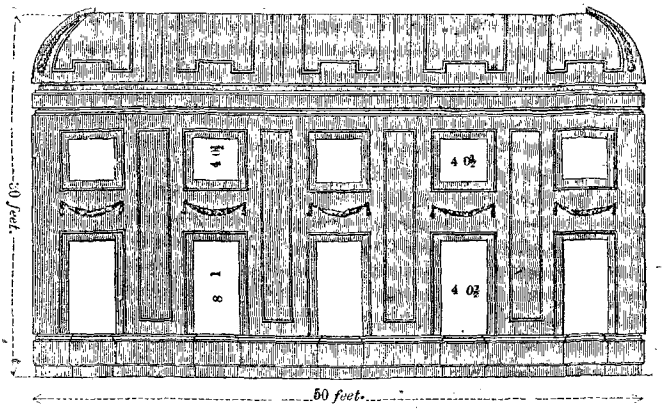

Fig. 967.

and to have two tire" (tiers) "of windows. Let us suppose the room (*fig.* 967.) with two tire of windows in height, to be 50 feet long, 40 feet wide, and 30 feet high, the arithmetical proportion of 5, 4, and 3, the product of those numbers multiplied together will be 60000, the square root of which sum is 245 superfical feet; divide that sum for the tire" (tiers) "of windows into three parts, or take one third of it, and that makes the attic or square windows 81 feet 8 inches superficial light; divide this into 5 windows, and they are 4 feet and half an inch square, and the five lower windows, consisting of 163 feet 4 inches superficial light, being what remains out of the 245 feet, the root, each of these windows is 4 feet and half an inch by 8 feet 1 inch, or two diameters, which 245 feet, the whole sum of the square root of the room, will sufficiently illuminate the same."

2754. The extreme piers should not, if possible, be less than half the width of the principal piers. This cannot always be obtained, but a much less width causes great irregularity, and that more especially when one of such end piers falls opposite a chimney breast, besides causing a great mass of shadow on the other side of the chimney, which has a tendency towards making the room dark and gloomy.

2755. Windows in the same story should be similar. There may be an occasional deviation for a great central window, but such deviation must be used with much caution. Another practice, most properly reprobated by Chambers, is that of intermitting the architrave and frieze of an order in the intervals between the columns to make room for windows and their enrichments, as on the flanks of the Mansion House in the city of London; a practice from which Sir Christopher Wren was, unfortunately, not exempt, as may be noticed in St. Paul's Cathedral.

2756. What are called Venetian windows are occasionally allowable, when so ranged and introduced as not to interfere with the composition, — a task often difficult to effect. They should not be much repeated, as in the front at Holkham, where they become actually disgusting. Though in the examples which follow there be two which are composed with semicircular-headed centres, we do not approve of the general use of examples designed on such principles, and would advise the student rather to study the composition of the Venetian window, when required, as in *fig.* 968., which we do not present as one of beauty, but rather of propriety, where the want of light to the apartment renders a Venetian window expedient. The method of making sashes, shutters, and the other accessories of windows has been described in a previous section; we therefore proceed to offer a few of the most celebrated examples of windows. It is not necessary, after the investigation relative to the voids and solids of doors, to pursue the inquiry into the relative proportions of windows as respects that part of the subject. They are, in a measure, in regard to windows, subject to the same principles, and this, by trial, will be immediately apparent to the student; and we therefore shall not stop for such investigation.

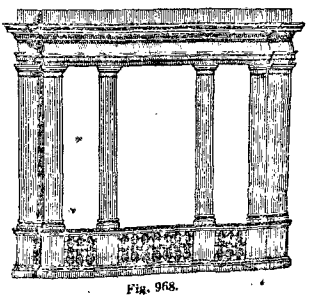

Fig. 968.

2757. *Fig.* 969. is after the lower story of windows at St. Peter's at Rome, by Michael Angelo, and is rather less than the double square in height. The architrave is one seventh

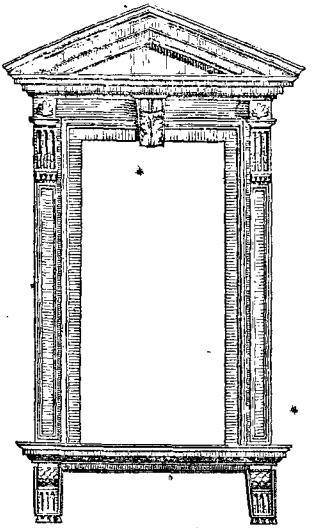

Fig. 969.

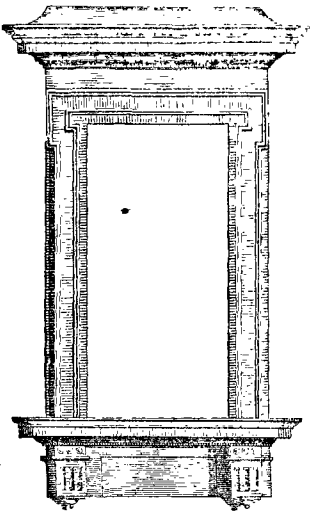

Fig. 970.

of the aperture's width, being the same as that of the pilasters. The length of the consoles is one third of the width of the aperture, and the entablature one quarter of its height.

2758. *Fig.* 970. is from the Mattei palace at Rome, and is the design of Bartolomeo Ammanati. It possesses, though rather heavy, considerable beauty, and well deserves the attention of the student. Chambers, from whom we have selected many of our examples in this and others sections, says, "the parts made somewhat less would succeed better, as would also a pediment instead of the sloped covering at top:" but we entirely disagree with him, and are of opinion that what he proposes would ruin the design.

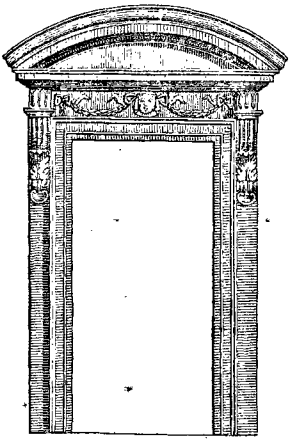

Fig. 971.

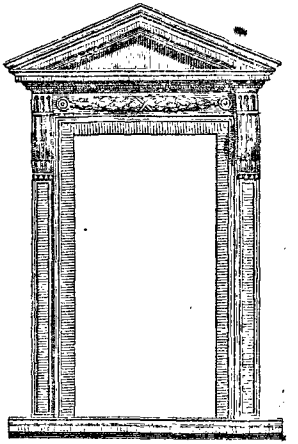

Fig. 972.

2759. *Figs.* 971. and 972. are the compositions of Bernardo Buontalenti. The apertures are a double square, or something less, the architraves a sixth or seventh of the apertures, and the pilasters may be about the same. The height of the entablature should not be more than a quarter that of the aperture, nor much less. The greatest length of the consoles should not exceed half the width of the aperture, nor should their least length be less than one third of it.

2760. *Fig.* 973. is from the old Louvre at Paris, and is by the celebrated Pierre Lescot,

abbot of Clugny in the reigns of Francis I. and Henry II. Its proportions are not much dissimilar from the two last examples.

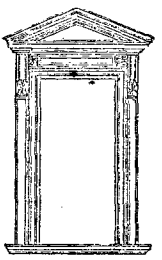

Fig. 973.

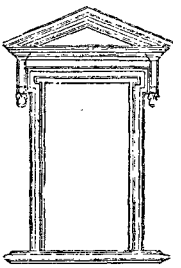

Fig. 974.

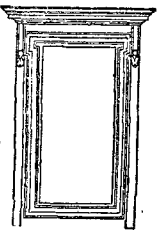

Fig. 975.

2761. *Fig.* 974. is a window constantly used by Palladio. The opening is a double square, the breadth of the architrave equal to one sixth of the aperture, and the frieze and cornice together equal to double the height of the architrave. The breadth of the consoles equal to two thirds the width of the architrave. The breaks over the consoles in the bed mouldings of the cornice are perhaps not strictly correct, but are deviations from propriety which may be tolerated. The breaks in the upper vertical parts of the architrave would perhaps be better omitted. The practice generally should be avoided, except in cases where a greater length of cornice is wanted for the purpose of filling the bare walls to which the windows are applied.

2762. *Fig.* 975. is from the Banqueting House at Whitehall, by Inigo Jones. The aperture is a double square, the entablature one fourth of its height, and the architrave somewhat more than one sixth of its width.

2763. *Fig.* 976. is by Michael Angelo, and executed at the Farnese palace at Rome. It possesses all the wildness and fancy of the master, and though abounding with faults, is redeemed by its grandeur and originality.

2764. In *fig.* 977. is given the design by Ludovico da Cigoli of a window from the ground floor of the Renuccini palace in Florence. It can scarcely be properly estimated without its connection with the façade, to the character whereof it is in every respect suitable.

2765. *Fig.* 978. is a design of Palladio, nearly resembling that executed in the Barbarano palace at Vicenza. It has been imitated by Inigo Jones, and perhaps improved on by him, in the flanks at Greenwich Hospital.

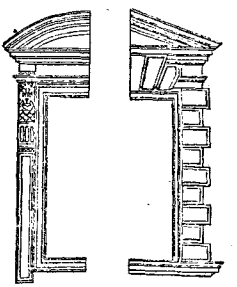

Fig. 976. Fig. 977.

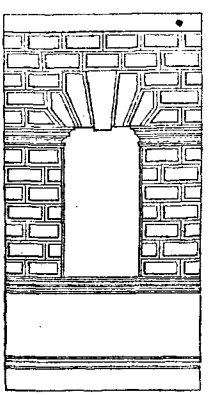

Fig. 978.

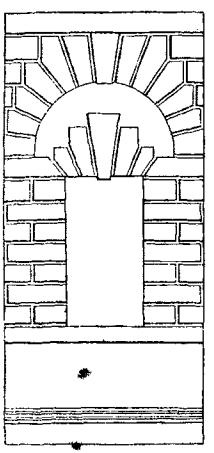

Fig. 979.

2766. *Fig.* 979. is also by Palladio, and executed by him in the Porto palace at Vicenza.

2767. *Fig.* 980. is the design of Raffaelle Sanzio, and worthy of the reputation of that

great painter and architect. It is executed in the Pandolfini palace at Florence, on the principal floor. The height of the aperture is a very little more than twice its width, the architrave is one seventh the width of the aperture. The columns, which are Ionic, are

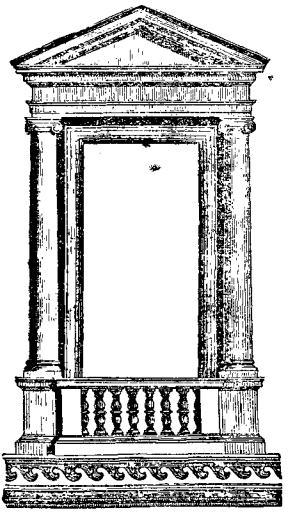

Fig. 980.

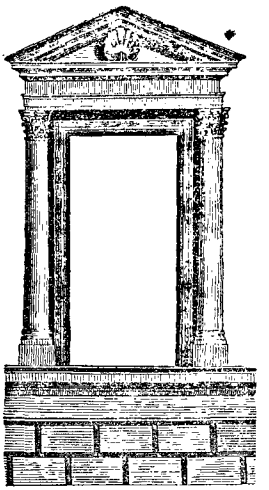

Fig. 981.

9 diameters high, and should be as much detached from the wall as possible. The distance of them from the architrave of the window is a quarter of a diameter, which is also the distance of the entablature from the top of the same architrave. The total height of the entablature is two ninths of that of the column, and the height of the pediment is one quarter of its base or somewhat less. The pedestals are one quarter of the height of the whole order.

2768. *Fig.* 981. is one of the windows of the Bracciano palace at Rome, by Bernini. The aperture is more than a double square, and the architrave about one sixth the width of the aperture. The entablature is only one fifth of the height of the columns, including their sub-plinths, and the pediment is less in height than one quarter of its extent.

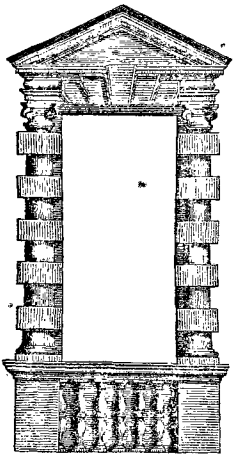

Fig. 982.

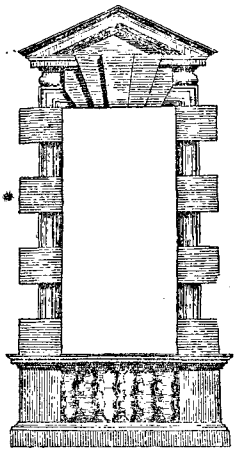

Fig. 983.

2769. *Fig.* 982. is from the principal floor of the Palazzo Thiene at Vicenza. The aperture is two and two tenths of its width in height; the columns are nine diameters high, and one quarter engaged in the wall. The under sides of the Ionic capitals are level with the top of the aperture, having angular volutes with an astragal and fillet below the volute. The bases are Tuscan, and there are on each shaft five rustic dies of an equal breadth.

whose inner sides are on a line with the sides of the aperture, and their projection equal to that of the plinth of the base, that is, one fifth of a diameter of the column. The keystones incline forwards towards the top, and they are hatched, only the surface being left rough, as are likewise the dies on the columns, except at their angles, which are rubbed smooth. The entablature is Ionic, the architrave consisting of only two fasciæ, the frieze swelled, and the dentil band placed immediately on the frieze, without any intervening mouldings, a practice not very unusual with Palladio. The pedestals are rather more than one-third the height of the columns. The dies and balusters stand on the platband of the basement, which was done to diminish the projection.

2770. *Fig.* 983. is a design by Inigo Jones, which has been much used in this country. It is rather higher than a double square. The width of the architrave is one fifth that of the aperture, and the rustics are a trifle less than the third of it.* The entablature is two ninths of the height of the opening, and the height of the pedestal is $\frac{37}{100}$, or nearly so, of the height of the aperture and pedestal taken together.

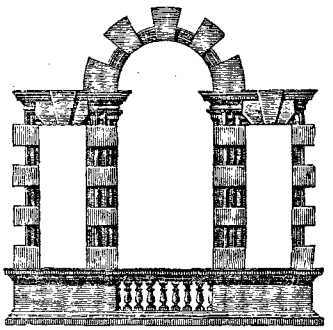

Fig. 984.

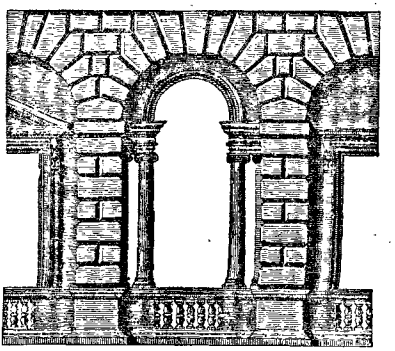

Fig. 985.

2771. *Fig.* 984. is the design of a Venetian window by Colin Campbell, the compiler of the three first volumes of the *Vitruvius Britannicus*; and

2772. *Fig.* 985. is very similar to the Venetian windows in the west façade of the Horse Guards, executed by Kent. It is perhaps as favourable an example of this species of window as can be produced.

Sect. XXI.

NICHES AND STATUES.

2773. A niche is a recess constructed in the thickness of a wall for the reception of different objects, such as statues more especially, but occasionally also for that of busts, vases, and tripods. Vitruvius makes no mention of niches, and but for an inscription published by Visconti in the *Monumenti Gabini* we should not have known that they were by the ancients called *zothecæ*, or places for the reception of a figure. Our English word niche is evidently derived from the Italian *nicchio*, a shell.

2774. In the early Greek temple the niche is not found; at a later period, as in the monument of Philopappus, we find a circular and two quadrangular-headed niches occupied in the time of Stuart by statues; and it does not seem improbable that in the Gymnasia, Agora, Stadia, &c. of the nation mentioned, the use of the niche was not uncommon. But the different forms of the ancient tomb, and the early methods of sepulture, would soon suggest to the Greeks and Romans the use of the niche, especially in such tombs as were devoted to the use of a particular family. These sepulchres, whose subdivisions were called *columbaria*, had their walls ornamented with small niches for the reception of cinerary urns, or those containing the ashes of the dead. In these, a large-sized niche occupies the principal place in the apartment, and in this was deposited the urn or sarcophagus of the head of the family.

2775. The small temples (*ædicula*) of the Romans are often found decorated with niches; and in the small building on the Lake of Albano, generally supposed to have been a Nympheum, we find each side of the interior dressed with six niches, whose height sufficiently indicates that they were provided for the reception of statues. In the temple of Diana, commonly called the *maison carrée*, at Nismes, which, however, is usually considered to

have been a building sacred to the Nymphs, the interior has two sides decorated with six Corinthian columns, and in the wall between each intercolumniation is a niche of the sort called tabernacles by the moderns. Each is placed on a pedestal, and is finished on the sides by pilasters alternately surmounted by segmental and triangular pediments. We do not, however, consider it necessary to enumerate the various Roman works wherein the niche finds a place, and shall therefore do no more than refer the student to the Pantheon, the temple of Peace, the arch of Janus, at Rome, and to its exuberant employment at Palmyra, Baalbek, and Spalatro. The buildings cited will furnish him with examples of all sorts and characters.

2776. The dresses of niches seem to bear an analogy to those of windows and doors in their form and decoration; the niche may really be considered as an opening in a wall, and indeed there are, in the arch of Claudius Drusus, now the Porta Maggiore, at Rome, openings used as niches, in which an object placed may be seen from either side of the wall. It therefore appears not improper to dress the niche with the ornaments which custom has sanctioned for doors and windows. The author of the article "Niche" in the *Encyclopedie Methodique*, has divided niches into three classes. The first are such as are square on the plan, and either square or circular-headed. These are the simplest, and are without dressings of any sort. Second, such as are square on their plans, and with square heads, but ornamented with dressings, or crowned with a simple platband supported by two consoles. In the third class are included all niches whose plan and heads are semicircular, either ornamented with festoons, or with dressings, or with columns and entablature. These, says the author, are to be introduced into buildings according to their several characters, from simple to highly enriched, as requisite.

2777. Some architectural authors have laid down positive rules for the proportions of niches. According to others the proportion is found in a niche twice and a half its width in height; and indeed this produces a proportion not inelegant. But in considering the classes separately, they have divided the width of the niches invariably into twelve parts. To a niche of the first class they give twenty-eight of such parts; to one of the second class, thirty; and to one of the third class, thirty-one parts. This reduction, however, of the proportions of a niche seems to us to partake of empiricism; and we would rather always trust to an educated eye than to rules which seem to have no basis on fitness and propriety. It is, moreover, to be recollected that all rules of art can be considered only as *mean terms*, serving more as approximations than positive laws for the guidance of the artist in the different combinations he imagines.

2778. The use of tiers of niches over each other is condemned by J. F. Blondel, unless separated by a line of entablature between them, which may seem to indicate the existence of a floor; otherwise, he observes, one figure seems to stand on the head of another. This, however, is an abuse of reasoning; not that it is to be understood that we think the practice very allowable. The recommendation of this master in respect of the relation between niches and the statues that are to occupy them is worthy of attention. He opposes, and we think with great propriety, the placing a statue without a plinth in the niche. The plinth is, indeed, necessary to the good effect of every statue; and to pretend that the imitation in marble could or ever was intended to be mistaken for the object it imitates, would be to leave behind all those matters of convention in art for which the spectator is well prepared. In architectural decoration, no less than in the abstract imitation of the objects of sculpture, no one is desirous of believing them natural and living, but only as models of imitation.

2779. The following observations are from Chambers, relative to the size of the statues used in niches. "The size of the statue depends upon the dimensions of the niche; it should neither be so large as to seem rammed into it, as at Santa Maria Maggiore, in Rome, nor so small as to seem lost in it, as in the Pantheon, where the statues do not occupy above three quarters of the height of the niche, and only one half of its width. Palladio, in arched niches, makes the chin of his statues on a level with the top of the impost (springing), so that the whole head is in the coved part. In the nave of St. Peter's, at Rome, the same proportion has been observed, and it has a very good effect. The distance between the outline of the statue and the sides of the niche should never be less than one third of a head, nor more than one half, whether the niche be square or arched; and when it is square, the distance from the top of the head to the soffite of the niche should not exceed the distance left on the sides. The statues are generally raised on a plinth, the height of which may be from one third to one half of a head; and sometimes, where the niches are very large in proportion to the architecture they accompany, as is the case when an order comprehends but one story, the statues may be raised on small pedestals, by which means they may be made lower than usual, and yet fill the niche sufficiently, it being to be feared lest statues of a proper size to fill such niches should make the columns and entablature appear trifling. The same expedient must also be made use of whenever the statues in the niches, according to their common proportions, come considerably larger than those placed at the top of the building. A trifling disparity will not be easily perceived, on ac-

count of the distance between their respective situations; but if it be great, it has a very bad effect; and therefore this must be well attended to and remedied, either by the above-mentioned method, or by entirely omitting statues at the top of the building, leaving the balustrade either free, or placing thereon vases, trophies, and other similar ornaments." Further on in the same work, the author says that "niches, being designed as repositories for statues, groups, vases, or other works of sculpture, must be contrived to set off the things they are to contain to the best advantage; and therefore no ornaments should ever be introduced within them, as is sometimes injudiciously practised, the cove of the niche being either filled with a large scollop shell, or the whole inside with various kinds of projecting rustics, with moulded compartments, either raised or sunken, or composed of different coloured marbles, for all these serve to confuse the outline of the statue or group It is even wrong to continue an impost within the niche, for that is of considerable disadvantage to the figures, which never appear so perfect as when backed and detached on a plain smooth surface. An excess of ornaments round the niche should likewise be avoided, and particularly masks, busts, boys, or any representation of the human figure, all which serve to divide the attention, and to divert it from the principal object."
